summary manner, and, if the report of the case be true and complete, we think he is fully justified in doing so, as the case was essentially one requiring complete investigation. There are cases in which the life history of the deceased, taken with other facts, is sufficient to warrant the coroner in declining to hold an inquisition, and in such cases it would be culpable to waste the public funds. On the other hand, in cases like the present, it is not only expedient but obligatory that an inquest should be held and a post-mortem examination made.

CAUSE OF GASTRIC DISTURBANCE IN PHTHISIS.

DR. GRUSDEFF suggests that the gastric disturbances so frequently associated with phthisis may be, in part at least, due to the copious night sweats, and that the indigestion so often met with in soldiers may very probably be connected with the large amount of perspiration occasioned by their long marches and heavy fatigue duty. He has found by a series of experimental observations that when a large amount of perspiration is induced in healthy subjects, the acidity, the quantity of free hydrochloric acid, and the digestive power of the gastric juice are diminished, and also that the quantity of the fluid secreted by the stomach is less than under ordinary circumstances. These effects, too, are not so transitory as might be imagined; their extent and duration depend upon the condition of the individual, and on the amount of the perspiration. Under some circumstances they persist for twenty-four hours. No effect appears to be produced upon the pepsin of the gastric juice or upon the acids of the urine.

SIR W. B. DALBY.

WE regret to learn that Sir W. B. Dalby has been confined to his bed for the past three weeks from synovitis of the right knee-joint following a sprain. We are glad to be able to state, however, that a turn for the better has taken place, and that the fluid is being rapidly absorbed. Mr. T. Pickering Pick is in attendance, and thinks that his patient will in a week or two be convalescent.

THE SANITARY STATE OF THE GOVERNMENT OFFICES.

NEWS often travels by a somewhat circuitous route; and we are now informed, through the *Northern Whig* office, that renewed complaints are being made as to the sanitary state of some of the Government offices in Whitehall, where several cases of typhoid fever are alleged to have taken place during the last few months, and where the drains are said to be in a very unsatisfactory state. The two offices especially referred to are the Local Government Board and the India Office. There is also complaint as to the "accommodation" of the Government officials, and the blame appears to attach primarily to the Office of Works.

REPORTED DEATH UNDER NITROUS OXIDE.

THE death is announced of Lady Milne, wife of Admiral Sir Alexander Milne, of Inveresk, Midlothian, who is stated to have "succumbed to the influence of 'gas' in a dentist's shop in Edinburgh, where she had gone, in company with her husband and daughter, in order to have a tooth extracted. After the administration of the anæsthetic she never recovered consciousness, the cause of death being presumably due to weakness of the heart." It will be interesting to hear further details concerning this sad event, the number of fatal cases on record being extremely small.

PREVENTING A POST-MORTEM EXAMINATION.

AT an inquest recently held at Farnham, Surrey, it transpired that one of the witnesses (we presume a relative of the deceased) had forbidden a medical man to make a post-mortem examination, although the coroner had issued orders for such. The witness in question asked the coroner if it was not imperative for the doctor to produce his authority when required. The matter ended with the coroner censuring the witness in question. There can be no doubt that the latter acted illegally in obstructing the medical man in the exercise of his duty. At the same time, we are of opinion that the doctor should be prepared to produce the coroner's order if demanded.

DR. BURDON SANDERSON.

DR. BURDON SANDERSON has been suffering from a local inflammatory affection, which has kept him to his room for some weeks. He is now practically convalescent, but has been advised to take a holiday away from home for the present, and will probably be unable to resume lecturing until after Christmas.

DOCTORS IN THE FRENCH CHAMBER OF DEPUTIES.

THE following list of medical men successful as candidates for the Chamber during the recent election in France is given by *La France Médicale*, No. 113. Twenty out of the twenty-two are Republicans, and the number is expected to be doubled by the second ballot. Ain: Dr. Herbet. Allier: Dr. Gacon. Alpes (Basses-): Dr. Isoard. Alpes-Maritimes: Dr Th. David, dentist at Paris. Corrèze: Dr. Labrousse. Dordogne: Dr. Theulier. Drome: Dr. Chevandier. Finistère: Dr. Le Borgne and Dr. Clech. Garonne (Haute-): Dr. Mandeville. Gironde: Dr. Alcée Froin. Hérault: Dr. Vernhes. Loiret: Dr. Viger. Lot: Dr. Rey. Marne: Dr. Thomas. Nièvre: Dr. Ducoudray. Pas-de-Calais: Dr. Haynaut. Pyrénées (Basses-): Dr. Quintaa. Rhin (Haut-): Dr. Grizez. Saône-et-Loire: Dr. Lucien Guillemant. Tarn: Dr. Compayré. Vendée: Dr. Bourgeois. The last Chamber contained fifteen medical men.

DANGERS OF CELLULOID ARTIFICIAL EYES.

DR. MEURER, of the Lyons Ophthalmic Clinic, has published a paper warning medical men against the practice of ordering their patients who may require artificial eyes to get those made of celluloid. Such eyes are cheap, it is true, and have a good appearance. At first, too, they seem to suit very well, but after three or four months they appear to undergo some chemical change and set up a serious amount of irritation. He has repeatedly seen this inflammation disappear on the removal of the celluloid eye by means of simple antiseptic treatment; reappearing, however, as soon as the old eye was put in again, but remaining absent if a glass eye was substituted.

METROPOLITAN HOSPITAL SUNDAY FUND.

WE are glad to learn that this fund has now reached the sum of £41,600, an amount which is just £1000 in excess of the best collection in years past. This is a very satisfactory fact, and one that detractors of the fund will do well to consider.

"THE ELECTROPATHIC AND ZANDER INSTITUTE: A PROTEST."

WE are informed by our solicitors that the Medical Battery Company, Limited, have given formal notice of discontinuance of the action brought by them against the Proprietors of this journal for libel (*vide* THE LANCET, April 20th, 1889, page 804).

Digitized by Google

THE report on the composition and quality of the metropolitan water-supply during the month of August, by Messrs. Crookes, Odling, and Meymott Tidy, shows that of the 175 samples examined two manifested a "very slight turbidity." The remaining 173 samples were found to be clear, bright, and well filtered. The improvement in the London waters apparent in July was well maintained during August. Dr. Frankland, in his analysis, states that, taking the average amount of organic impurity contained in a given volume of the Kent Company's water during the nine years ending December, 1876, as unity, the proportional amount contained in an equal volume of water supplied by each of the Metropolitan Water Companies and by the Tottenham Local Board of Health was:—Kent, 0·4; New River, 1·1; East London, 1·2; Colne Valley, 1·3; Tottenham and West Middlesex, 1·6; Southwark and Grand Junction, 1·8; Chelsea and Lambeth, 1·9.

THE Italian Pharmaceutical Association opens its second general Congress in Rome at the close of the present week. The members, upwards of 3000 in number, will be largely represented, many of the leading pharmacists from Turin to Palermo having signified their intention of assisting at the proceedings. Besides discussions on the new edition of the "Pharmacopœia Italica," on the status of the profession, and on its claims to recognition by the Government, the programme will include the special consideration of the higher culture of the pharmacist, for which object the universities will be memorialised to grant greater facilities; while, for the possessors of academic qualifications, the Ministry of Health will be approached with a view to their being made eligible for appointments in the department of State medicine, especially as directors of laboratories of chemistry in its application to public hygiene.

A SERIES of four demonstrations on the subject of Bacteriology are about to be given in Glasgow, by Mr. Ernest Maylard, to practitioners. They will be held in the Pathological Theatre of the Western Infirmary, on Tuesdays and Fridays, commencing on Friday, Oct. 18th, at 2 o'clock. They will be open free to all medical men on intimating to the superintendent of the Western Infirmary their desire to attend.

AT the meeting last Tuesday of the London County Council, on the motion of Dr. Longstaff, it was agreed, "That it be an instruction to the Sanitary and Special Purposes Committee to report to the Council as to the desirability of establishing public slaughter-houses throughout London, and as to the facilities which such a system would afford for the better inspection of the meat-supply."

MR. H. N. MILTON, medical officer at the Kasr-el-Aini Hospital, Cairo, informs us that Porro's operation was performed in the hospital on Sept. 5th. The child was extracted alive, the uterus removed, the pedicle tied with an elastic ligature, and fixed to the abdominal wound. Death of the mother occurred on the third day from septic peritonitis.

THE Gresham Lectures on Heredity or Inherited Characteristics will be delivered on October 8th, 9th, 10th, and 11th, at 6 P.M., by Dr. E. Symes Thompson, at Gresham College, Basinghall-street, E.C. The lectures are illustrated by diagrams.

DR. J. S. CAMERON, medical officer of health for Huddersfield, was on Wednesday last appointed medical officer of health for Leeds, at a salary of £700 a year and allowances, in place of Mr. Goldie, resigned.

AS will be seen in another column, the Committee for the proposed Voluntary Examination in Shorthand for Medical Students have made arrangements to hold this examination on October 11th. It will be interesting to observe to what extent the pursuit of this subject has been followed by those who are entering upon a medical career or who are already students of medicine.

IT is announced from Vienna that an "Anglo-American Medical Association" has been formed in that city (offices, 12, Landesgerichts-strasse), with the object of forming a reunion among the numerous English-speaking medical men who go there for study, and providing them with every information. Such an office, properly directed, should prove of great service.

THE French Congress of Surgery will commence its sittings on Monday next, the 7th inst., in the large amphitheatre of the Faculty of Medicine, under the presidency of Baron Larrey. The serious business of the Congress will begin on the following day.

THE sudden death on Wednesday last is announced of Mr. R. E. Power, L.R.C.P. Lond., L.R.C.S. Edin., the Governor of Woking Female Prison. Mr. Power was for many years medical officer of the Portsmouth convict prison.

MR. JONATHAN HUTCHINSON, jun., F.R.C.S. Eng., has been elected Assistant Surgeon to the London Hospital, in the vacancy caused by the resignation of Mr. Couper.

THE Harveian Oration will be delivered at the Royal College of Physicians on Friday, the 18th inst., at 4 P.M., by Dr. James E. Pollock.

DR. DAVID W. FINLAY, F.R.C.P., has been appointed Consulting Physician to the Royal Caledonian Asylum, in the room of the late Dr. G. Owen Rees, F.R.S.

THE PARIS UNIVERSAL EXHIBITION.

(FROM OUR SPECIAL CORRESPONDENT.)

The British Food Section.—International Free Education Congress.

THAT we must eat to live and not live to eat is an excellent maxim; but, like many other hard-and-fast principles, it is exposed to inconsistent compromises when introduced into actual practice. In visiting the great galleries, the immense stretch of space allotted at the Exhibition to all that is embraced within the generic term "alimentary products," grave doubts will be entertained as to whether we do not live to eat instead of eat to live. The truth presumably lies somewhere between the two propositions; and, though we must eat to live, it is very certain that if eating is not rendered pleasant, we shall not live well. Prominent among the purveyors of food to the world, and acting evidently according to the middle course just suggested, may be mentioned the numerous exhibitors in the British Food Section. It is a curious fact that although France is essentially the country for *bouillon*, yet it is in the English section that the greatest number of broths are exhibited. And here a word of praise must be accorded to the displays made by Messrs. Brand and Co. with their essences of meat, peptones, meat lozenges, and other preparations useful in cases of prostration; as also to the various meat extracts prepared by Baron Liebig, Messrs. Mason and Co., Messrs. Johnston with their "Bovril," and by the manufacturers of "Bouillon Fleet," all of which find patrons amongst the visitors to the Exhibition. But intermingled with all these there are Yorkshire

Digitized by Google

pies and turtle soups, sauces and various delicacies, which certainly suggest that it is worth while to live for the sake of eating. This is, indeed, the lesson of the whole section, and the only difficulty is to know how to select out of such an array of so many good things. Commendation is also called for by the displays made by Messrs. Macfarlane, Lang, and Co., of Glasgow, with their biscuits, fancy and otherwise, but notably a digestive biscuit called "Granola;" and by Messrs. Fry and Sons, with their chocolates and other sweets.

By the side of these food exhibits we have numerous stalls where British beverages tempt the thirsty foreigner. English beer enjoys, perhaps, an exaggerated reputation in France. Even in England we are seeking to imitate the German beers, which have the advantage of being much lighter. Thus, the Tottenham, export Pilsener beer has many admirers, whilst ordinary English ales, such as those exhibited by Messrs. J. Stocks and Co., of Halifax, Messrs. Shillingford and Co., and, again, Messrs. Mitchell and Co., of Smethwick, are in great demand. The large sale of English beer in France is undoubtedly a fact of growing importance. First, we are led to ask how far such beer can advantageously replace the wine usually drunk? Will the beer be purer, more free from adulteration than the wine? The increase of dipsomania has been very marked in France since wine has become difficult to procure in consequence of the phylloxera. Can beer, and especially English beer, advantageously take its place? By the immense preference given to German or Strasbourg beer, it would seem that this is not probable.

The increase of drunkenness, especially in the northern parts of France, is due, not only to the dearness of wine and the consequent sale of bad or semi-artificial wines, but also to the increased consumption of spirits naturally resulting from the difficulty of getting good wine. The question then arises whether English distillers could throw on to the French market more wholesome alcohols, and thus in a measure counteract the evil effects produced by the vile spirits drunk in France, especially by the poorer classes. One thing is certain: the Food Section contains some excellent English alcohols, amongst which may be specially mentioned the Irish whiskies of Bushmill's Old Distillery Co., county Antrim, and of Dunville and Co.; the Scotch whiskies of John Stewart, of Edinburgh, and Archibald Lander, of Glasgow; whilst English alcohols are well represented by Holland and Co., Deptford, whose gin seems of excellent and wholesome quality. The stall of the Salutaris Water Company also calls for praise. Important, as likely to promote the cause of temperance, if we admit that excess is largely due to the impurity of wines and spirits, is the very imposing show of the South Australian Wine Growers' Association. This is a collective exhibit, which has received a Government subsidy of £1000. No merchants or intermediaries are concerned in this exhibit; the wines come direct from the wine growers, and it is a Government agent who represents them. Of their purity there can be little doubt; the difficulty will be to get the wines into the hands of the public in a manner as direct as that by which they are exhibited in Paris. These wines reproduce, by imported vines planted and grown in South Australia, some of the most celebrated *crues* of Europe; some also that in Europe have ceased to exist. For instance, the Frontignan grape at Frontignan has been completely killed; but from Australia we now get a very good Frontignac wine. It is such wines—that is, sweet dessert wines—which have been most appreciated at the Exhibition. A wine named Sercial, grown in two or three of the largest vineyards of South Australia, seems to specially flatter the French palate. Then there is also the celebrated Tokay. The Australian Tokay is, however, somewhat lighter and sweeter than what I have tasted in Hungary. Some of these wines are very well suited for mixing with quinine and for other medical purposes. The clarets are about 20 per cent. stronger than French *vin ordinaire*, and, in proportion to strength, about the same price. Of course, they will stand travelling better, and also exposure. There is, or there should be, greater guarantee of their purity, and the supply is evidently destined to become unlimited. Thus, from Australia we may receive the answer to the vexed question how to give the masses a cheap, pure, and wholesome drink that, though stimulating, is not too strong.

An interesting International Congress has been held this week to promote the cause of free education; education free from dogma, from excessive official control, and absolutely *integral*. By this very useful French word the idea of completeness is conveyed; it means that everything is to be taught if the pupil is capable of learning. From the public health point of view the doctrines enunciated by this congress were important. M. Desmoulin, till quite recently Municipal Councillor of Paris, was in the chair at most of the sittings, but after the opening meeting held at the Hôtel de Ville the Congress, out of compliment to the foreign nationalities represented, elected Mr. Adolphe Smith (for England) as President, and Madame Polousky (for Russia) as Vice-President. There were a great many Russian and Polish teachers present, and delegates from Belgium, Italy, Mexico, the United States, and Switzerland. The greater number were teachers, but I noted also a few medical men, and the women delegates were nearly as numerous as the men. So far as the debates bore on questions connected with public health, the following were the principal points elucidated. Firstly, teaching was to be based exclusively on scientific principles, deductions from actual experiments. Instead of being told, the child was to be made to discover, if possible, that which it is desired to teach. Every natural proclivity was to be encouraged; a child should never be forced in any direction, and should never be overworked. The classes were to follow each other in such a manner as to provide the greatest possible change, and thus prevent weariness. But, above all, the children were to be fed, and well fed. The delegates were unanimous in denouncing the hardship endured by underfed children, and the impossibility of teaching under such conditions. The Swiss delegate declared that in primary schools of several cantons not only were free meals provided, but even articles of clothing were given away, so that the children of the poor should not suffer from cold while at their lessons.

For the preservation of the morality of children the congress was strongly in favour of mixed schools. Just as brothers and sisters were brought up together in the family, so ought boys and girls to work together at school, and they should have both masters and mistresses. Each sex had its special capacities, and the children should profit by both. There was far more decency when the sexes were together. Sometimes a master married one of the schoolmistresses; sometimes even among the children playmates later in life became husband and wife; but there was not that immorality which prevails to so large an extent in both boys' and girls' schools or convents where the sexes are separated. The experience of mixed schools in Switzerland and in Germany helped to confirm, the delegates maintained, these theories. Also there was far more emulation when the sexes were mixed.

Mr. Adolphe Smith introduced a resolution demanding that, "In view of preserving public health, it should be obligatory to teach in all schools and to both sexes the elementary laws of hygiene, including the principles of drainage, ventilation, and disinfection." He explained how the mortality in different centres of population in England had been reduced by one-third in consequence of the application of sanitary laws. But it was necessary that each person should be sufficiently acquainted with these laws to apply them in his own home and to vote for the election of such municipal councilmen, vestrymen, and members of Parliament as would promote wise legislation on the subject. For all these reasons it was necessary to teach the good doctrine early; and no better lesson could be given than the object lesson of a school properly built and free from all sanitary defect. In this respect it was fortunate that the Congress was international, for the Congress would have a great deal to learn from English schools so far as the drainage was concerned; but the English had much to learn from France with respect to the unilateral light and to the ventilation and warming of school-rooms which was more scientifically arranged in France. The Swiss delegate, in supporting the resolution, insisted forcibly on the necessity of building schools in accordance with sanitary laws; as the masters would be placed in an absurd position if they taught pupils principles of hygiene which were not applied in the *locale* where the lessons are given A Polish delegate protested that, while most persons talked of hygiene, very few persons knew anything at all about the question. It was time that the science was properly and systematically taught. The Congress then unanimously voted in favour of the resolution.

A considerable sensation was produced by Madame Chéliga-Loévy's report on the condition of education in

Digitized by Google

Poland. Everything was done to prevent the free development of thought. The Government wanted doctors and engineers; but, on the other hand, looked on education as a danger, as a power that menaced social order. Hence the universities and the upper schools were checked in their development by all manner of prohibitory decrees. In one province, possessing 7,000,000 inhabitants, there were only twenty schools for secondary education. The children of poor parents were by law excluded from the universities, and only those who were very rich and considered favourable to the Government were admitted. The want of doctors, engineers, and educated men in Russia would soon assume the proportions of a national calamity. Madame Corradi, a Russian delegate, described the torture of children set to uninteresting tasks of Latin and Greek, taught like parrots, not allowed to think, and so uselessly and stupidly overworked that suicide among school children had become quite epidemic in Russia.

The Congress, at its last sitting, decided to constitute itself into an International Association of Educators, and M. Francolin, 174, Faubourg St. Denis, was elected international secretary. The Association will seek to promote in every country the cause of free and scientific education.

SANITATION IN BENGAL.[1]

THE Report of the Sanitary Commissioner for Bengal just issued comprises four subjects: (1) The vital statistics of the general population; (2) general history of the chief diseases; (3) sanitary work (civil); and (4) personal proceedings. As regards the first of these—the vital statistics of the general population,—the system of registration in Bengal is still so very imperfect that no reliance can be placed upon the returns either of births or deaths. Dr. Gregg gives several instances of the results of the imperfect registration of births, and remarks, "it is needless to observe that these figures are ridiculously inaccurate." As regards the deaths, the Lieutenant-Governor, in calling attention to fourteen municipalities in which the reported death-rate ranged between 6·67 and 12·79 per 1000, "is constrained to remark that these results are very discreditable to the municipal committees, especially in the case of those municipalities in which the Act has been in force for many years. It is obvious, as remarked by the Sanitary Commissioner, that the registration both of births and deaths is still so extremely defective that no trustworthy conclusions can be drawn from it, either with regard to the general health of the province, or the healthiness of the year under report, as compared with that of previous years." We hope, though we are by no means sanguine, that the steps recommended to be adopted to improve the registration may result in obtaining more reliable data on these important points.

The history of the chief diseases, though wanting in numerical accuracy as a measure of the death-rate of the people, may be usefully studied as indicating the chief causes of mortality and leading to a study of those measures by which they may be ameliorated or removed. The death-rate in the Province as shown by the returns amounted to 22·94 per 1000 of population, and of this 16·53, or upwards of two-thirds, appear under the head of fever. The months in which the mortality from this cause is highest are October to January inclusive, and those in which it is lowest are June and July. "The high mortality during the last three months of the year is undoubtedly due to malarial fever caused by the marshy and waterlogged condition of the country after the rains." The cause of fever was pointed out many years ago by Dr. D. B. Smith, the late lamented Professor of Hygiene at Netley, to be chiefly want of drainage, partial or complete stagnation of watercourses, and saturation of the soil with moisture. The adoption of a well-devised and efficient system of drainage, therefore, would appear to be the most likely means of combating this source of disease and death, and with it provision should also be made for the supply of wholesome water, as there can be no doubt that a considerable amount of fever is due to the impure and filthy quality of that which is too often the only available. The disease next in importance as a cause of death is cholera, by which in 1888 there were 11,391 deaths registered, being 1·68 per 1000 of the population at the last census. It was most fatal in May and July. "The departmental reports do not cast any new light upon the etiology of cholera. ..... The civil surgeon's reports, however, contain evidence which is in the main confirmatory of the view that outbreaks of cholera are traceable to pollution of drinking water, and that dissemination of the disease is largely dependent on water fouling." This affords an additional reason for improving the water-supply and protecting it from contamination. Of the other diseases none gave rise to a high death-rate; that from bowel complaints was 0·79 per 1000, and from injuries 0·40. Of the latter, wounds and accidents caused one-half, snake-bites and wild beasts one-fourth, and suicide one-tenth. It is worthy of remark that the number of suicides recorded was greater among women than men, in about the proportion of 3 to 2, but it is possible this may be a result of the defective registration. Under the head of "Sanitary Works (Civil)," Dr. Gregg calls attention to the very insignificant amount expended on sanitary works and improvements, such as drainage, water-supply, and public latrines, which are among the most urgent requirements of the province; and he also strongly advocates the disposal of the dead by cremation, which, he states, when completely and properly carried out, is free from anything offensive either to sight or smell. The abstracts of the inspection reports afford melancholy evidence of how little has been done to improve the towns since the last inspection, and of how much remains to be done before they can be deemed in a fairly good sanitary condition.

[1] Twenty-first Annual Report of the Sanitary Commissioner for Bengal for the year 1888, by Surgeon-Major W. H. Gregg, M.B.

HOSPITAL REUNIONS.

St. Bartholomew's.—The annual dinner of the old students of St. Bartholomew's Hospital was held on Tuesday evening in the great hall of the hospital, Mr. John Langton in the chair. About 120 sat down to dinner, and grace was said by the Vicar of the parish, which is completely covered by the hospital. The usual loyal toasts, as well as those of the school, the hospital, the visitors, the chairman, and the secretary of the dinner were drunk with enthusiasm. Dr. Hill, Master of Downing College, Cambridge, a former scholar of the school, was one of the guests of the evening, as also were Professors Humphry and MacAlister, the Registrar of the Royal College of Physicians, and Sir Frederick Abel. After dinner coffee was served in the library.

St. Thomas's.—On Tuesday afternoon the Medical Session at the School attached to this hospital was inaugurated by the usual delivery of an introductory lecture. Mr. W. Anderson gave the address in the afternoon at three o'clock in the large female operating theatre. Mr. Anderson had selected for his subject, the "History of Surgery," and throughout there was the greatest attention paid by the large audience present to a most interesting and learned address. At 6.30 P.M. the annual dinner was held in the Governor's Hall of the hospital, and there was a large meeting of members of the staff, and old and present students of the hospital. The chair was taken by Dr. John Harley, who, after the usual loyal toasts, proposed the "Army, Navy, and Reserve Forces," to which Surgeon Harris, A.M.D., Mr. Mackellar, and Sir W. MacCormac responded. To the toast of "St. Thomas's Hospital," proposed by the Chairman, Mr. J. G. Wainwright, one of the governors, and an almoner of the hospital for sixteen years, responded, in the absence of Mr. Alderman Stone, the treasurer. Mr. Wainwright referred to the financial condition of the hospital and to the good understanding which exists between the medical staff and the hospital authorities. Mr. John Croft proposed the "Health of the Chairman," who briefly replied. Mr. Nettleship, the Dean, responded to the toast of the "Medical School," proposed by Professor Charles Stewart. Dr. Ord proposed the "Old Students," and Mr. H. Lavers of Colchester and Mr. W. F. Haslam of Birmingham replied. The "Health of the Secretaries" (Dr. H. P. Hawkins and Mr. H. B. Robinson) was proposed by Mr. Sidney Plowman, and they each briefly replied. At the termination of the official toast list Mr. W. F. Haslam proposed the "Health of Mr. Plowman," the sentiments to which he gave utter-

Digitized by Google

ance being enthusiastically received, and Mr. Plowman briefly replied.

Middlesex.—The annual dinner of the past and present students of this hospital was held on Tuesday evening in the Venetian Salon of the Holborn Restaurant. There was an unusually large number present, and the festival was most successful. Dr. Douglas Powell was in the chair, and was supported by nearly all his colleagues, by several members of the Weekly Board of the hospital, and by a large number of old Middlesex men. After dinner the usual toasts were duly honoured. In a very happy speech Dr. Powell proposed the toast of the evening, the "Middlesex Hospital and Medical School," which was responded to by Mr. Bell-Sedgwick, the vice-chairman of the Weekly Board, who has been a member of the board for over thirty-five years, and by the dean, Mr. Pearce Gould. The toast of the "Past and Present Students," proposed by Mr. Hulke, was responded to by Mr. Freeman, who is now mayor of Bath, and by Mr. Daniel, the senior Broderip Scholar. During the evening Mr. Wilhelm Ganz played a pianoforte solo, and Mr. Hulbert Fullerson and Mr. Charles Ganz sang various songs. The dinner, the speeches, and the music were all declared to be excellent.

St. George's.—At the conclusion of the introductory address by Dr. Clifford Allbutt on Oct. 1st, the usual ceremony of the distribution of the prizes was presided over by Sir Henry Pitman, and, after a few forcible and encouraging words to the students, the following honours and certificates were awarded:—Entrance Scholarships of £125 and £50, to Mr. A. R. Rendle and Mr. E. G. Little; £65 Scholarship for Oxford and Cambridge men, to Mr. G. E. Hale, of Cambridge; the Johnson Prize in Anatomy, to Mr. H. A. Hinge; the Pollock Prize in Physiology, to Mr. N. Elrington; the Acland Prize in Clinical Medicine, to Mr. W. K. Fyffe; Sir Charles Clarke's Prize, to Mr. F. Jaffrey. Mr. H. S. Barkworth obtained the Brackenbury Prize in Surgery, the Thompson Medal, and the Treasurer's Prize. The General Proficiency Prizes were obtained by Messrs. R. M. Walford and R. G. Turner. In the evening the annual dinner of the Medical School was held at the Métrôpole, under the presidency of Dr. A. T. H. Waters of Liverpool. In proposing the toast of the Medical School, the Chairman laid great stress on the want of additional space both for the school and the hospital, a suggestion which apparently met with the unanimous approval of the company present.

Guy's.—The winter session at Guy's Hospital opened with the first meeting of the Physical Society on Tuesday, Oct. 1st, at 8 P.M. Dr. Samuel Wilks occupied the chair and inaugurated the meeting with a kindly welcome to the new students of the hospital and a short address to the past and present Guy's men who formed a large portion of the audience. Dr. Barrs of Leeds then read a paper on "Some Recent Changes in Medical Education," which was well received; and the proceedings terminated with a vote of thanks to the chairman. Tea and coffee were provided, and there was a fine exhibition of photographs, pathological drawings, microscopic sections, and surgical instruments in the large rooms of the student's club.

King's College.—About seventy past students of King's College dined together on Tuesday, Oct. 1st, at Limmer's Hotel, Conduit-street, under the presidency of Dr. John Walters of Reigate. A very pleasant *réunion* took place, and the speeches of the chairman, Mr. T. H. Cheatle of Burford, Oxon., Mr. John Teale of Scarborough, and Dr. Gage Brown, C.M.G., were full of reminiscences of old King's College teachers and students. The Principal, Dr. Wace, replied to the toast of the King's College Medical School and Hospital, and the Dean, Dr. Curnow, proposed the health of Sir A. Rollit, LL.D., M.P., as the lecturer of the day.

The London.—On Tuesday, Oct. 1st, at 7 P.M., close upon two hundred old London Hospital men sat down to a substantial and well-served repast in the new library of the Medical College. Dr. Langdon Down, the senior physician to the hospital, presided, and was supported by Jonathan Hutchinson, Esq., F.R.S., President of the Royal College of Surgeons; F. C. Carr-Gomm, Esq., chairman of the Hospital Committee; Professor George Buchanan, Glasgow; and many other colleagues and friends. After the usual loyal toasts, "Prosperity to the College" was proposed by the chairman, and responded to in a humorous speech by Mr. Rivington, who compared the present state of the College with that of thirty years ago. Mr. Hutchinson proposed the health of his friend and fellow-student, the chairman. During the dinner a telegram was received from Sir Andrew Clark, conveying his sorrow at being unable to be present owing to indisposition, and great regret was expressed by all at his unavoidable absence. The "Health of the Visitors" was proposed by Mr. Frederick Treves, and replied to by Professor Buchanan and Mr. Carr-Gomm. During and after the dinner, which was provided and served by Mr. Holland, the manager of the Students' Club, instrumental and vocal music was provided by Mr. T. Lawler. Dr. Stephen Mackenzie, Mr. Rivington, and Mr. Openshaw acted as secretaries on the occasion. Shortly after 11 o'clock the company separated, after an extremely enjoyable evening.

Westminster.—The session was opened on Wednesday, in the presence of a majority of the staff and of a large number of students and friends, Professor Alexander MacAlister, F.R.S., of Cambridge, occupying the chair. After the dean of the school (Dr. Donkin) had presented his report, which gave a satisfactory account of the general condition of the school, and especially of the successes of the Westminster men at the various examinations, Dr. P. S. Abraham (Lecturer in Physiology) was called upon to deliver the inaugural address. The school prizes were then awarded by the chairman. The prizemen included Mr. A. S. G. Bell (Treasurer's Prize), Mr. W. H. Tebbs (President's Prize), Mr. Yearsley (Bird Prize), Mr. Llewelyn Lewis (Clinical Medicine Prize), and Messrs. Stonham, Byles, G. A. S. Bell, Garrard, Tebbs, Harrison, Brice, A. S. G. Bell, Yearsley, and others (various class prizes and certificates). Professor MacAlister then made some appropriate remarks, and congratulated the school upon its excellent results. In the evening, the staff, several of the governors of the hospital, and many of the past and present students of the hospital, dined together at the Holborn Restaurant, Dr. Dupré, F.R.S., being in the chair. The toast of the evening, the "Westminster Hospital Medical School," was proposed by Professor MacAlister, and other toasts were spoken to by the chairman, Dr. Allchin, Mr. Cowell, Dr. Sturges, Dr. Donkin, Mr. Macnamara, the Rev. Mr. Jones, the Rev. Mr. Echalaz, Dr. Pearse, Mr. Hunt, Mr. Sharman, and others. The proceedings were enlivened by a programme of music rendered by some of the students.

THE SANITARY CONGRESS.

THIS institute resumed its deliberations in congress at Worcester on Thursday, Sept. 26th, at the Guildhall, the president, Mr. G. W. Hastings, M.P., in the chair.

The prophylaxis of diseases.—Sir Douglas Galton, K.C.B., D.C.L., LL.D., F.R.S., in presence of a large audience, delivered an address on the subject of certain groups of diseases which were amenable to the control of preventive measures. These diseases were small-pox, typhus, enteric fever, scarlatina, measles, whooping-cough, diphtheria, cholera, and phthisis. They were now able to point with unerring certainty to the fact that, given certain conditions of impure air, impure water, and a soil saturated with filth, sickness and death from one or other of these preventable diseases would ensue. Commencing with small-pox, the lecturer said that, through vaccination and revaccination, that disease had been almost entirely obliterated in the German army, and largely in German cities. But in England we have not been so careful in enforcing either vaccination or revaccination, and we have suffered, even in recent years, from severe small-pox epidemics. Typhus fever, which was a common and very fatal disease at the beginning of the century, was essentially associated with overcrowding and destitution. It used to be the inhabitant of our gaols, under the name of "gaol fever," which was of so infectious a character that on more than one occasion the judge, the jury, and the bar caught the fever from the prisoners in the court. Typhus was essentially the disease of the pauper and badly housed elements of the community, but wherever it prevailed it might be caught by those around who were within the sphere of its influence. Scarlatina had no such relation to water-supply and drainage as had those other preventable diseases of which enteric fever is a type. Recent investigations appeared to make it certain that the cow suffered from a disease of the nature of scarlatina,

Digitized by Google

which was in some way communicable to man through the milk. Hence the necessity of enforcing in our houses and farmyards sanitary conditions of cleanliness and pure air. The laws governing the spread of cholera were well understood by sanitarians. Figures showed that these zymotic diseases, which Dr. Farr has aptly called "filth diseases," had of late years been largely reduced by sanitary means. Sanitation necessarily meant the increased well-being of the people, and especially of the lower class. Epidemics could only be prevented by making the whole population sanitary, and the speaker proceeded to give some valuable advice on the subject of the conservation of the general health, concluding by producing a number of statistics showing the meaning of the preventable cause of death.

Chemistry, meteorology, and geology.—On the following day (Friday, Sept. 27th) Dr. J. W. Tripe opened this section with an address, taking for his special subject winds, with remarks on their sanitary effects. He commenced by minutely describing the constituents of the atmosphere, and considered the direction of the wind in relation to its effect on the general health. Easterly winds in this country were very trying, even to healthy persons, and often fatal to the young and old, causing more deaths in London when combined with fog in one week than the most violent blizzard. He accounted for certain outbreaks of infectious diseases by winds blowing in the direction affected. Some physicians, he said, doubted the possibility of small-pox infection being carried more than a few feet; but he could not understand how, if a disease be set up by a living organism, falling on a soil which it would develop, it should be able to infect a person at 20 ft. distance, and not at 100 ft., or even at half a mile. Surely a living organism could not be destroyed (oxidised) in its passage through the air for half a mile when the wind was travelling at the rate of only four miles an hour; and yet articles of infected clothing and scabs of small-pox they knew would retain infective power for months.

The proceedings of the Congress came to a close on Saturday, Sept. 28th, when Professor W. H. Corfield, M.A., M.D. Oxon., F.R.C.P., addressed a working men's meeting at the Worcester Public Hall on "the Mistakes made in Life and the Remedies for those Mistakes." In infancy parents should, above all, not make the mistake of letting their children be too thinly clad, nor commit the common mistake of supplying infants with improper food. The only proper food for children was that which nature provided—the mother's milk. Boiled bread, tea and starchy foods, should be especially avoided in the case of infants until their salivary powers had developed. The diarrhœa of infancy generally arose from improper feeding and rickets, called by foreigners the "English disease." One of the greatest mistakes, again, in the treatment of children was not to have them vaccinated before they were three years old. As to their exposure to cold, it was a monstrous mistake for parents to send out their children with bare necks, heads, and legs. Children ought to be clothed from head to foot winter and summer. Children required plenty of sleep, plenty of food, together with variety either in work or play. It was, however, necessary that children should go to bed early. The worst of all habits to acquire in youth was that of drinking alcoholic spirits at any time except at meals, and of drinking "nips." On the subject of teetotalism he would not trench. Under no circumstances should tobacco smoking be encouraged in youth. At manhood, the time of marrying and giving in marriage, he cautioned his hearers against intermarrying with members of families in which nervous or consumptive diseases were hereditary, as those diseases would be certain to recur in the offspring. At middle age the most common mistake was overfeeding, and in old age the wearing of scanty clothing leading to bronchitis.

HONG-KONG.

THE annual report of the Colonial Surgeon of Hong-Kong for 1888 shows the health of the Colony, as measured by the death-rate and mean sick of the troops and police, to have been unsatisfactory. Among the European troops the admissions into hospital were 1045, the deaths 12·46, and the mean sick 53·94 per 1000 of strength; among the Asiatic troops they were 803, 28·09, and 28·09 respectively. Although the admissions were lower than in 1887, the deaths in both classes and the mean sick of the Europeans were considerably higher. The deaths among the European and American residents were also much higher than in any of the preceding nine years; but as the numbers living are manifestly incorrectly stated, it is impossible to make an accurate comparison. The increase in the death-rate of the Europeans and Americans appears to have been due to an outbreak of small-pox, which caused 29 of a total of 122 deaths. The death-rate in the police force was 21·90 per 1000; among the Europeans 8·7, the Indians 18·0, and the Chinese 28·6 per 1000 of each class respectively. From an average daily number of 531 prisoners in Victoria Goal the cases of sickness amounted to 808 and the deaths to 28·25 per 1000, both much higher than in the preceding year. The high death-rate was due to choleraic diarrhœa, which was the cause of 7 in a total of 15 deaths. Two of the other deaths were those of prisoners killed in an attempt to escape from the chain gang, and one was by suicide in the cells. As in previous years, the mortality in the Tung Wa Hospital was very high, 1428 deaths having occurred among 2456 patients; 276 of the deaths were from small-pox, and 379 cases were moribund on admission.

In the appendix to the report is a paper on the prevalence of beri-beri among the water police of Hong-Kong by Mr. Atkinson, the Superintendent of the Government Civil Hospital. It appears that of 121 men of this force whom he examined, 17 have had the disease, and during the year 1888 it had been the cause of death of 5 men in a strength of 130. It is stated to be very common in Hong-Kong, and the treatment adopted would seem to bear out the opinion of the Director-General of the medical department of the navy of Japan that this disease depends, in a great measure at least, on the quality of the food of the men (*vide* THE LANCET, July 9th, 1887). In the water police the men provide themselves with food.

In the report of the Government analyst three investigations in connexion with cases in which symptoms of poisoning occurred are noted. The first was a case in which datura alba was supposed to have been mixed with a fish stew; the second was one of alleged tea drugging; and the third one in which twenty-two men of the band of the Northamptonshire Regiment were affected with "burning pain in the stomach and violent vomiting, causing partial collapse," supposed to have been caused by cheese, of which they had partaken for supper. In none of the cases could satisfactory evidence be obtained in confirmation of the charge of poisoning. In connexion with the hospital considerable improvements appear to be in progress, but are not yet completed. Mr. Ayres, moreover, points out the need for the construction of a suitable laundry with a small hospital disinfecting apparatus, and also a building for the reception of all cases of infectious diseases.

SOCIETY FOR THE STUDY OF INEBRIETY.

AT a meeting held on the 1st inst. (the President, Dr. Norman Kerr, in the chair), a paper was read by Mr. H. C. Trestrail, on Inebriety and some of the Circumstances leading thereto. The circumstances of birth, as exemplified in heredity, the use of alcohol during lactation, and defective education were dwelt on, the necessity for self-control being enforced. There should be education as to the action of narcotics. Inebriety was a disease demanding sound scientific and judicious medical treatment. The President, in replying to the question, Is there an arsenic inebriety, responded in the negative, though he had known iodine, arsenic, and other similar substances taken to excess. Only narcotics and anæsthetics, such as opium, alcohol, and ether, gave rise to a true narcomania, though a permanent impress might be made on the nerve-centres by any substances. It was resolved to memorialise the Home Secretary and Government to use their influence to promote the appointment of a Parliamentary Committee to inquire into the results of the working of the Inebriates Acts. Another resolution was passed approving of the leading principles of Mr. Charles Morton's Restorative Homes (Scotland) Bill—viz.: (1) voluntary reception and detention without appearance before a justice; (2) compulsory admission and detention of inebriates unable or unwilling to apply of their own accord; (3) provision at the public charge for the detention and treatment of impecunious

Digitized by Google

inebriates. Among those who took part in the discussion were Messrs. Jabez Hogg, H. W. Williams, G. K. Poole, Hazell, Paramore, and Parsons (West Worthing).

EXTENSION OF MARISCHAL COLLEGE.

WITH a view to extending the University Buildings in New Aberdeen, the university authorities some time ago acquired several of the old houses adjoining the College, and, to make way for the present extensions, seven houses are to be cleared away. The new buildings are to be erected parallel to, and between, the south wing of Marischal College and Longacre, and will measure 168 ft. in length, 27 ft. in width, and 57 ft. in height, and will consist of four storeys. Amongst other conveniences, there will be two large animal observation rooms, a hygienic museum, a bacteriological laboratory, a materia medica practical class-room, a physiological practical class-room, a medical jurisprudence practical class-room, and numerous other departments connected with medical study, all designed on the most modern and approved principles. The new buildings, which have been designed by the Government architect for Scotland, Mr. W. W. Robertson, are to be ready for occupancy by March, 1891, and the total cost of the present extensions will be between £5000 and £6000.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Birmingham, City.—Last year, according to Dr. Alfred Hill, Birmingham attained the lowest death-rate it has ever been able to record—namely, one of 17·5 per 1000,—and considerable improvement existed as regards the more preventable diseases, such as fever and diphtheria. The authority are, however, very properly warned that some at least of this satisfactory state of affairs was due to exceptionally favourable climatic conditions; and we may now add that scarlet fever, which last year was just rising from its lowest ebb, has since then given evidence of how such diseases run in cycles; indeed, in 1888 that disease was still lying all but dormant. The infantile death-rate was also low in Birmingham last year in comparison with previous years. As usually, it was to an important extent made up of infantile diarrhœa, and to this disease Dr. Hill devotes some attention, quoting, among other things, the whole of Dr. Ballard's general report to the Local Government Board on the subject. The abolition of the filthy form of midden privy, heretofore almost general, is steadily proceeding; the need for a proper abattoir is becoming more and more pressing; the dairies, milkshops, and cowhouses are looked after, and are especially reported on; as are also the canal boats and the bakehouses. The infectious hospital received 528 cases of scarlet fever and 18 of small-pox, and resort to the hospital for the purposes of isolation is stated to be becoming more and more popular. An excellent disease chart, which, however, includes neither diarrhœa nor small-pox, appears in the report, in addition to other matter both tabulated and in the form of diagrams.

Bollington Urban District.—With a population estimated at 3900, Bollington had last year a death-rate of 18·2 per 1000. Mr. Allen's report is a brief one in so far as the sanitary circumstances of the district are concerned, but it is stated that back yards and streets are still in a very defective state as regards paving, that some improvement has taken place as to dwelling accommodation, that drainage and other nuisances have been attended to, and that the dairies, cow sheds, and milk shops have been inspected as heretofore.

Kingston-upon-Thames.—This district had in 1888 the lowest general and zymotic death-rates on record—namely, 14·2 and 0·68 per 1000 living, the population being 23,490. Diphtheria, formerly somewhat prevalent, almost disappeared last year, and Dr. Shirtliff desires to point out that this result has occurred concurrently with a system of disconnexion of house drains, although he declines to tie himself to the view that the two events are necessarily related to each other as cause and effect. A constant water-supply remains to be provided. The question of the disposal of the sewage is reported to have been most satisfactorily dealt with, and the dual system of notification is referred to as working in a harmonious way.

Ealing Urban District.—Assuming the population of this West-end suburb to be 22,800, Dr. Patten finds the death-rate to have been 10·9 per 1000 for last year. The zymotic mortality was also small; but Ealing is well prepared to meet any emergency by having an excellent isolation hospital, which continues to be resorted to by all classes, and especially by so-called private patients, who have a small isolation room to themselves. Private roads have been improved during the year, and there has been a continuation of good current sanitary work.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN twenty-eight of the largest English towns 5501 births and 3285 deaths were registered during the week ending Sept. 28th. The annual rate of mortality in these towns, which had been 16·2, 16·9, and 17·0 per 1000 in the preceding three weeks, further rose last week to 17·9. During the thirteen weeks ending on Saturday last the death-rate in these towns averaged 18·6 per 1000, and was 1·6 below the mean rate in the corresponding periods of the ten years 1879-88. The lowest rates in these towns last week were 7·9 in Huddersfield, 12·5 in Nottingham, 14·7 in Oldham, and 14·9 in Norwich. The rates in the other towns ranged upwards to 27·6 in Sunderland, 28·0 in Blackburn, 31·0 in Preston, and 32·7 in Plymouth. The deaths referred to the principal zymotic diseases, which had been 529 and 537 in the preceding two weeks, declined again last week to 529; they included 258 from diarrhœa, 67 from scarlet fever, 60 from diphtheria, 60 from whooping-cough, 56 from "fever" (principally enteric), 28 from measles, and not one from small-pox. These zymotic diseases caused no death last week in Derby, and the highest death-rates in Blackburn, Preston, and Plymouth. The greatest mortality from diarrhœa occurred in Sunderland, Newcastle-upon-Tyne, Bolton, Wolverhampton, Blackburn, and Preston; from scarlet fever in Blackburn and Plymouth; from whooping-cough in Plymouth and Wolverhampton; from "fever" in Salford, Portsmouth, and Halifax; and from measles in Newcastle-upon-Tyne and Norwich. The deaths from diphtheria included 44 in London, 4 in Portsmouth, 3 in Manchester, 3 in Salford, and 2 in Plymouth. Small-pox caused no death in any of the tweny-eight great towns; and no small-pox patient was under treatment at the end of the week either in the Metropolitan Asylum Hospitals or in the Highgate Small-pox Hospital. The number of scarlet-fever patients in the Metropolitan Asylum and the London Fever Hospitals at the end of the week was 1247, against numbers increasing in the preceding thirteen weeks from 559 to 1171; 166 cases were admitted to these hospitals during the week, against 196 and 128 in the two previous weeks. The deaths referred to diseases of the respiratory organs in London, which had been 152 and 142 in the preceding two weeks, rose last week to 189, but were 34 below the corrected average. The causes of 69, or 2·1 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Salford, Oldham, Portsmouth, and in six other smaller towns; the largest proportions of uncertified deaths were registered in Liverpool, Cardiff, and Hull.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 19·1 and 16·4 per 1000 in the preceding two weeks, rose again to 18·8 in the week ending Sept. 28th; this rate exceeded by 0·9 the mean rate that prevailed during the same week in the twenty-eight large English towns. The rates in the Scotch towns ranged from 9·5 in Perth, and 16·6 in Edinburgh and in Dundee, to 20·7 in Glasgow, and 25·2 in Leith. The 481 deaths in the eight towns showed an increase of 62 upon the number in the previous week, and included 30 which were referred to diarrhœa, 14 to

Digitized by Google

whooping-cough, 11 to "fever" (typhus, enteric, or ill-defined), 9 to diphtheria, 6 to measles, 4 to scarlet fever, and not one to small-pox; in all, 74 deaths resulted from these principal zymotic diseases, against 79 and 74 in the preceding two weeks. These 74 deaths were equal to an annual rate of 2·9 per 1000, which corresponded with the mean rate last week from the same diseases in the twenty-eight English towns. The fatal cases of diarrhœa, which had been 38 and 36 in the preceding two weeks, further declined last week to 30, of which 13 occurred in Glasgow, 7 in Dundee, and 5 in Edinburgh. The 14 deaths from whooping-cough were within one of the number in the preceding weeks, and included 9 in Glasgow and 2 in Edinburgh. The 9 fatal cases of diphtheria exceeded the numbers in recent weeks; 3 were returned in Leith and 2 in Dundee. The deaths referred to "fever," which had been 11 and 6 in the preceding two weeks, rose again last week to 11, and included 6 in Glasgow and 2 in Edinburgh. Five of the 6 fatal cases of measles were returned in Glasgow, and 2 of the 4 deaths from scarlet fever in Leith. The deaths referred to acute diseases of the respiratory organs in the eight towns, which had been 61 and 66 in the preceding two weeks, further rose last week to 89, and exceeded by 10 the number returned in the corresponding week of last year. The causes of 58, or more than 12 per cent., of the deaths registered in the eight towns during the week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 18·6, 24·5, and 28·5 per 1000 in the preceding two weeks, further rose to 31·5 in the week ending Sept. 28th. During the thirteen weeks ending last Saturday the death-rate in the city averaged 24·0 per 1000, the mean rate during the same period being 16·5 in London and 15·9 in Edinburgh. The 213 deaths in Dublin last week showed a further increase of 10 upon the numbers returned in the previous three weeks; they included 23 which were referred to diarrhœa, 6 to "fever" (typhus, enteric, or ill defined), 1 to measles, and not one either to small-pox, scarlet fever, diphtheria, or whooping-cough. Thus the deaths from these principal zymotic diseases, which had been 20 and 31 in the preceding two weeks, were last week 30; they were equal to an annual rate of 4·4 per 1000, the rate from the same diseases being 2·4 in London and 2·0 in Edinburgh. The deaths attributed to diarrhœa, which had been 11, 15, and 18 in the previous three weeks, further rose last week to 23; the 6 deaths from "fever" showed a decline of 2 from the number in the previous week. The deaths of infants showed a considerable increase, while those of elderly persons had declined. Five inquest cases and 7 deaths from violence were registered; and 55, or more than a quarter, of the deaths occurred in public institutions. The causes of 43, or more than 20 per cent., of the deaths in the city were not certified.

THE SERVICES.

ARMY MEDICAL STAFF. — Surgeon David Middleton Greig, M.B., resigns his commission (dated Oct. 2nd, 1889).

ARMY MEDICAL RESERVE OF OFFICERS. — Surgeon Charles Arrol, M.D., 3rd Volunteer Kent Brigade, Cinque Ports Division, Royal Artillery, to be Surgeon-Major, ranking as Major (dated Oct. 2nd, 1889); Surgeon Richard Joseph Bryden, 3rd Volunteer Brigade, Cinque Ports Division, Royal Artillery, to be Surgeon, ranking as Captain (dated Oct. 2nd, 1889).

ADMIRALTY.—In accordance with the provisions of Her Majesty's Order in Council of April 1st, 1881, Surgeon John Cashin has been placed on the Retired List of his rank; Surgeon Matthew Digan has been allowed to withdraw from Her Majesty's Naval Service, with a gratuity.

The following appointments have been made:—Surgeon John J. A. Costello to be Surgeon and Agent at Carnsore and Rosslare (dated Sept. 26th, 1889); Staff Surgeon Thos. M. Sibbald to the *Canada* (undated); Staff Surgeon George D. Twigg to the *Royalist*, Staff Surgeon Archibald M'Kinlay to the *Egeria*, Staff Surgeon John B. B. Triggs, M.B., to the *Pylades*, Staff Surgeon George W. Bell to the *Tourmaline*, and Staff Surgeon Henry J. Madders, M.D., to the *Hecla* (all dated Oct. 6th, 1889); Surgeon Bowen S. Meuds to the *Canada* (dated Oct. 6th, 1889); Surgeons George Wilson, M.B., and Harold F. D. Stephens, M.B., to the *Pembroke* (both dated Sept. 27th, 1889); Staff Surgeon Michael J. M'Carthy, M.D., to the *Cruiser*, and Staff Surgeon James Porter, M.A., M.B., to the *Scout* (both dated Oct. 3rd, 1889); Surgeon Charles W. Sharples to the *Melita*, Surgeon Octavious W. Andrews, M.B., to the *Duke of Wellington*, and Surgeon Francis M. Puddicombe to the *Royal Adelaide* (all dated Oct. 3rd, 1889).

VOLUNTEER CORPS.—1st Volunteer Battalion, the King's (Shropshire Light Infantry): Acting Surgeon F. K. P. Pigott to be Surgeon (dated Sept. 28th, 1889).—*Memorandum:* Infantry Volunteer Brigade—Eastern Counties Brigade: Surgeon and Surgeon-Major S. M. Hopson, 3rd Volunteer Battalion, the Norfolk Regiment, to be Brigade Surgeon, ranking as Lieutenant-Colonel (dated Sept. 28th, 1889).

PROFICIENCY EXAMINATION FOR VOLUNTEER MEDICAL OFFICERS.—An order has been recently issued from the Home District Office notifying, for the information of Officers commanding Volunteer Corps, that the examination of Volunteer Medical Officers for certificates of proficiency on Army Form E 564 will in future be held quarterly on the first Tuesday in each quarter, commencing October 1st, 1889. Names of medical officers desirous of attending these examinations should reach the Home District Office at least a week before the date of examination. In order to prepare medical officers for the examination to be held next January, a course of six lectures will be given by Surgeon Walter Pearce, M.D., B.Sc., 20th Middlesex (Artists) Rifle Volunteers, on Thursday, Nov. 7th, 1889, and following five Thursdays, at the Headquarters of the Queen's Westminster Rifle Volunteers, Buckingham-gate, St. James's-park, S.W. For further particulars application should be made to the Hon. Secretary, R. R. Sleman, 7, St. Benet-place, Gracechurch-street, E.C.

Correspondence.

"Audi alteram partem."

THE USE OF THE ELECTRO-MAGNET IN OPHTHALMIC SURGERY.

To the Editors of THE LANCET.

SIRS,—The efficacy of the electro-magnet in the removal of fragments of steel or iron from the interior of the eye has been attested by too many to permit of any question as to its value; moreover, it rightly finds a place in all the text-books on ophthalmic surgery. I confess, then, it is somewhat disappointing to find a clinical lecture by Dr. Jeaffreson advocating, without allusion to the magnet, methods for removal of splinters of steel or iron from the iris, which were all very well some years ago, but are, to say the least, crude with the knowledge we now possess as to the capabilities of magnets and electro-magnets. There can be no question that numbers of eyes have been saved by the timely use of the electro-magnet which would otherwise have been lost; and it is the sense of this fact, founded on large experience of the employment of the electro-magnet and of accidents previously to its introduction, that impels me to write these few lines. From different regions of the eye I have removed seventy-three fragments of steel or iron; many of these I have recorded from time to time, and the whole have been incidentally alluded to in my address[1] as President of the Yorkshire Branch of the British Medical Association. Of this number, eight have been from the iris and anterior chamber. In such a case of foreign body in the iris as Dr. Jeaffreson mentions, the electro-magnet would have been valuable in two ways: 1. On approaching the electro-magnet to the cornea the presence and nature of the foreign body would have been immediately evident by its springing forward to the back of the cornea, or, if entangled much in the iris, by its dragging that membrane towards the magnet. In some cases it is possible to guide the foreign body in the anterior chamber to a convenient locality for removal, and then to drop it on the iris at the selected point. 2. After making a small corneal incision and advancing the point of the electro-magnet to or inside the wound, the fragment would have been extracted adhering to it, and very probably, as generally happens, without any necessity for removing a segment of iris. Such cases have not only occurred in my own practice, but in that of others,

[1] Brit. Med. Jour., July 13th, 1889

Digitized by Google

and it was my good fortune to be present at Moorfields some years ago, when Mr. G. Lawson extracted with my electro-magnet a splinter of metal from the anterior chambers of two patients.

I will merely add that my observations on the use of the magnetic needle, with cases illustrating its value, were put on record some years since.—Yours truly,

Sheffield, Oct. 1889. SIMEON SNELL.

MEDICAL AID ASSOCIATIONS AND FRIENDLY SOCIETIES.

To the Editors of THE LANCET.

SIRS,—An attempt having been made here to start a branch of the National Medical Aid Company, and a Medical Aid Fund for the familes of a Lodge of Oddfellows, a meeting of the medical men of this district was called to discuss the question, and, as a result, the following pledge has been signed by twenty-one out of twenty-three of those either in or retired from practice; one of the exceptions is a retired surgeon, the other a practitioner who has promised to sign it as soon as he is free from his medical refereeship, of which he has sent in his resignation to the National Medical Aid Company. Such societies have been so disastrous elsewhere to our profession, that we feel it necessary to make a stand against their establishment here. I subjoin a copy of the pledge, in order that our profession in other places may be encouraged and strengthened against such combinations against its welfare:—

"We, the undersigned members of the medical profession of Malvern and its neighbourhood, taking into consideration the fact that there are well-established provident dispensaries in our midst, pledge ourselves not to undertake the care of families of members of friendly societies at a contract rate of payment."—I am, Sirs, yours faithfully,

Malvern, Sept. 30th, 1889. STANLEY HAYNES, M.D.

NAPHTHALIN.

To the Editors of THE LANCET.

SIRS,—Referring to the article on naphthalin in THE LANCET of last week, I should like briefly to draw attention to the great temporary value of this antiseptic in cases of infantile diarrhœa and fetid urine. Rickets—by far the greatest creator of infantile diseases, the neurosis maker, the slime producer on respiratory, colonic, and vesical mucous membrane, and the bone deformer—is the chief parent of stinking stools and foul urine. Naphthalin in cachets, containing two grains for each year of the age of the infant, and given twice or three times a day, will alleviate the path of recovery whilst the dietetic errors are being rectified. Naphthalin will not restore health to any mucous membrane flabby from rickets, but it will tend to do so, assisting in the process of recovery. A return from a rachitic constitution to a healthy one can never be brought about unless an attempt be made to increase vitality, whilst the metabolism is brought back to healthy modes of working by, in one word, a diabetic diet. The treatment of rickets, for one week at least, is the treatment of diabetes. A meat diet even without milk, persevered in for a few days, has caused slimy, worm-infested motions to disappear, bronchitis to subside, and nocturnal restlessness to be replaced by calm, refreshing sleep.

I am, Sirs, yours faithfully,

Oct. 1st, 1889. ANGEL MONEY.

INFECTIOUS DISEASE IN LONDON.

To the Editors of THE LANCET.

SIRS,—In view of the remarks made in the first paragraph of your leading article of last week, may I ask you to favour me by inserting in your next number a copy of a letter which I wrote to Mr. Ritchie when the Notification Bill was in Committee.

I have the honour to be your obedient servant,

EDWARD SEATON.

George-street, Hanover-square, Oct. 2nd, 1889.

"August 4th, 1889.

"To the Right Hon. C. T. Ritchie, M.P., President of H.M. Local Government Board.

"SIR,—Having been one of the earliest advocates of the notification of infectious diseases to sanitary authorities, and having taken an active part in securing its adoption and its subsequent practical working, I may address you on the Bill which is now in Committee, and which will soon become an Act of Parliament. I understand that the London County Council is promoting, or intending to promote, an amendment that notification should be made to them. If this proposal means that the County Council claims to be the first to be informed of the existence of infectious disease, I beg to remind you that, at present, that body has no executive duties with regard to those diseases; and that to make it in the first place the recipient of the information would be to the disadvantage of "the executive"—viz., the vestries and their medical officers of health, and consequently to the public. If the proposal means that the County Council desires to receive information periodically as well as the Metropolitan Asylums Board, then it would be easy for them to obtain that information from the Asylums Board, which, as the hospital providing authority for London, is part of "the executive" and has a well-recognised claim on medical officers of health. Information obtained from that Board or given by it once a week would be surely sufficient for any purposes the County Council may have in view. There is precedent for such a course in the case of your honourable Board's medical department, which receives information once a week from the medical officers of health in the notification towns. I cannot think of any valid reason why the County Council should have earlier or more frequent information than that which is supplied to the medical department of your Board.

"I beg respectfully to submit my representation and argument to your consideration, and have the honour to be

"Your obedient servant,

"EDWARD SEATON."

THE MAYBRICK CASE.

To the Editors of THE LANCET.

SIRS,—If judges and juries could see through Dr. Kerr's spectacles would-be poisoners would have a good time of it. When he says that the evidence on every point was very much stronger against Miss Smith than against Mrs. Maybrick, he surely forgets that on the first indictment against the former the verdict was "innocent." I have spoken to many here on the subject of the Maybrick trial, and I have only met with one who did not consider the case "proven" against the prisoner. I leave Dr. Kerr to his own opinions, but believe I am justified in saying that his suggestion that a Scotch jury would have brought in a verdict of "not proven" in the Maybrick case is an imputation on the national intelligence which must be repudiated.

I am, Sirs, yours truly,

Partick, Glasgow, Sept. 30th, 1889. R. KIRK, M.D.

*** The discussion of this subject must now cease.—ED. L.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

Scarlet Fever in Birmingham.

AT present there seems to be no abatement in this epidemic. Seventeen new cases were reported on Monday last, as against eleven on the Monday preceding. Seven patients were discharged from the Borough Hospital and eight were admitted. The new wards have been rapidly built, and now afford increased accommodation for forty patients; the number in the hospital stands at 320, so that the additional space will enable the authorities to provide ample room for the purpose required. A letter has been addressed to the local press by the Chairman of the Health Committee, stating that the danger has been much exaggerated. He points out that the city at the present time is suffering from one of those recurring periods when scarlet fever reaches the height of its development, and that, owing to the improved sanitary condition of the town, and the steps taken for isolation and treatment of the patients; the visitations occur at much longer periods and made no appreciable addition to the death-rate. Thus, "during the decade 1870 to 1879 the number of deaths from scarlet fever in this city averaged 419·1 per annum, the numbers in the years 1874 and 1878, when the scarlet fever waves reached their highest points, being 737 and 995 respectively; while during the nine years 1880 to 1888 inclusive they only averaged 114·7 per annum, and up to Sept. 27th the number for this year has been but 87." These facts are conclusive in themselves, and when it is added that most of the cases are of a mild type, it will be recognised that the causes for alarm are not so great as many people are inclined to believe. Among the hospital nurses all the infection has been of a light kind, and, with the exception of two, they are all convalescent. Mr. Eustace Hill, whose condition was at one time reported as dangerous, I am glad to learn is in a fair way of recovery.

Queen's College.

The annual conversazione and distribution of prizes took place on the 1st inst., the Warden, the Rev. W. H. Poulton, presiding. It was stated that the total entry in the medical

Digitized by Google

department for full and partial curriculum had been 59, and the number of students on the books 224. This was the first year in which the number of the students had exceeded 200. The passes obtained by students during the year had numbered 178, and of these 3 were at intermediate and 6 at final university examinations, and 128 at intermediate, and 41 at final examinations of licensing corporations.

Mason College.

The opening of the tenth session, and distribution of prizes, took place on the 1st inst. An address was given by Professor R. S. Heath, Chairman of the Academic Board. It was pointed out that there were 704 students in attendance during the past session.

Birmingham, Oct. 1st.

NORTHERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENT.)

Opening of the College of Medicine of the University of Durham at Newcastle.

THE handsome pile of buildings erected for the College of Medicine of the University of Durham, and of which the Duke of Northumberland laid the foundation-stone about two years ago, was formally opened by the Mayor of Newcastle to-day. There was a large attendance of the profession, students, and the general public, and the proceedings were lively and interesting, and passed off very successfully. The College, which provides for every requirement of students and professors, is designed in the Elizabethan style, stands in a convenient situation, and is built of red brick with terra-cotta dressings, except the mullioned windows and entrance archway, which are of stone. I described the interior arrangements in a previous letter. Dr. Heath, the President of the College, said that so far the building had cost £31,000, and there was still a debt of £10,000 upon it. He made a stirring appeal to the public spirit of the inhabitants of the district for their aid in the removal of this debt, the completion of the building, and the endowment of the chairs, which he said would cost £40,000 altogether. Dr. Heath then delivered an eloquent address on sanitary science, and finished by handing the treasurer the handsome gift of 1000 guineas. It may be remembered that Dr. Gibbs of this city at the commencement of the building also gave £1000 towards the fund. The veteran Dr. Embleton was present, and was congratulated on his good health and spirits. Dr. Embleton, it may be mentioned, was a student in the old and original school of medicine in Newcastle, which was then carried on near the town walls about fifty years ago. To-night a very large attendance is expected at the conversazione in the college.

Hartlepools.

The Marquis of Londonderry last week inaugurated the new Headland Promenade at Hartlepool. It is a sea wall and a massive work costing £25,000. It slopes in thickness from eleven feet at the bottom to eight feet at the top, and varies in height from twenty-one to twenty-seven feet. It stretches from the Corporation-road to the Lighthouse, and placing a broad-based wall in front of the crags that were irregularly worn, a promenade of magnificent proportions is provided for the inhabitants of this ancient borough, whose mayoral list reaches back to 1315. Another function was performed at the same time by Lord Londonderry—namely, the opening of the extension of the Hartlepools Hospital which owes its original erection largely to the munificence of the Burdon family, and which it has been found needful to enlarge to meet the growing needs of the Hartlepools and their increasing population. At all events this extension fully provides for the present wants of the two towns. Lord Londonderry's tasks on the opening day would see the happy completion on our coast of works of difficulty, and objects of usefulness costing together close upon £35,000.

Middlesbrough.

The Middlesbrough Trades Council held their annual Hospital Sunday demonstration on Sunday last under the most auspicious circumstances. They marched through the town in large numbers to the Theatre Royal, where the Mayor (Major Raylton Dixon) presided, whose name is well known in connexion with hospital and ambulance work. The collections which were taken *en route*, and would be devoted to the North Riding Infirmary and Cottage Hospital, considerably exceeded those of last year.

Newcastle-on-Tyne, Oct. 2nd.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

EDINBURGH.

Edinburgh University Gathering.

THIS year the admirable example set by Oxford last year has been followed by Edinburgh, and, before the commencement of the regular session, there has been instituted a series of lectures to those interested in science, art, and literature, who have not the opportunity of attending more extensive courses. A most influential committee of ladies and gentlemen has taken the matter in hand, and so far as can be judged from the continued attendance at the lectures, the movement has been attended with most marked success. The objects of the gathering are stated to be—1. To draw public attention to the means provided in the university extension scheme for improving the knowledge and elevating the tastes of the people. 2. To give all who have not had the benefit of a university training an opportunity of getting a little experience of university life, and to awaken in some, if possible, an enthusiasm for some definite line of study. 3. To consider as to organising a reading circle for Scotland. The committee have certainly been most wise in the selection of their lecturers. Professors Tait, Masson, and Crum Brown could scarcely be equalled, and, certainly, not excelled, in any list that could be drawn up. In the section which is of most interest to medical men, that of biological science, Professor Crum Brown leads the way, and is followed by Professors Cossar, Ewart and P. Geddes, and Drs. Barry Haycraft, A. P. Aitken, G. Sims Woodhead, and J. Arthur Thomson. It is, perhaps, fortunate that this gathering takes place during the period that the post graduate classes are being carried on, so that those who wish may listen to some of each of the sets of lectures, and, if they feel so inclined, may attend the conversazione, the special service in St. Giles' Cathedral, or some of the numerous and interesting excursions that have been arranged in connection with the gathering. Edinburgh men might take a note of this, as a factor to be taken into consideration when next year's plans are being matured.

Legacies to Edinburgh Medical Charities.

During the year to 30th September, a sum of £30,444 14*s.* has been left to the Edinburgh Royal Infirmary in the form of legacies and donations of £100 and upwards, and the Convalescent Home has been the recipient of no less than £3237 19*s.* 8*d.*

Edinburgh Health Reports.

During the quarter ended September the death-rate was 14·49 per 1000 of the estimated population, as compared with an average of 15·64 for the last five years. Diseases of the chest accounted for 24·20 per cent., and zymotic diseases for 9·30 per cent. In the Fever Hospital the number of cases admitted during the quarter was 338, and 253 were discharged. The daily average number of patients in hospital has been comparatively high this year: 131, as against 78 in the corresponding quarter of last year. Thirty patients died. It is seen from the report that a step in the right direction has been taken in respect to compensation for confiscated meat. During last month 10,289lbs. of unsound meat were seized as unfit for human food. In the case of one animal suffering from tuberculosis £18 4*s.* 9d. was paid in compensation.

Chair of Physiology in Dundee.

The only Edinburgh name mentioned as yet in connection with the new Chair of Physiology in Dundee, is that of Dr. Noël Paton. Should Dr. Paton decide to compete there can be no doubt that his reputation as a scientific worker and a most successful teacher would gain for him much support in his candidature.

Edinburgh, Oct. 1st.

GLASGOW.

The City's Population in 1889.

Dr. Russell, having obtained the data on which he calculates the population of the city proper every year—namely,

Digitized by Google

the return of inhabited houses within the municipality as at June 1st—now sets the number down as 551,478 persons; adding to this 6126, the number of inmates in institutions, as ascertained by special census, the total population is found to be 557,604. This is arrived at by multiplying 116,223 (the number of occupied houses) by 4·745 (the average number of inhabitants per house in 1881). We have thus an increase of 1360 houses over last year, and of 6169 souls. The following is a table of the successive movements of the population since last census in 1881:—

1881 to 1882	increase	19,166 or 3·74	per cent.
1882 ,, 1883	,,	10,228 ,, 1·92	,,
1883 ,, 1884	,,	4,250 ,, 0·78	,,
1884 ,, 1885	decrease	2,383	
1885 ,, 1886	increase	2,025 ,, 0·37	,,
1886 ,, 1887	decrease	1,325	
1887 ,, 1888	increase	7,440 ,, 1·37	,,
1888 ,, 1889	,,	6,169 ,, 1·12	,,
At inter-census rate ..	,,	2,056 or 0·39	,,

Medical Education for Women in Glasgow.

There seems to be some prospect of this matter being taken up in Glasgow, even during the present winter. St. Margaret's College has it under consideration, but there are difficulties in the way, especially as regards provision for clinical instruction. The teachers in Anderson's College medical school are understood to be favourable to the admission of women to their classes, and to be ready to undertake the management of "mixed" classes of male and female students. The Victoria Infirmary, to be opened in January next, would provide an excellent field for the clinical training of ladies, and the governors of that Infirmary are now considering the advisability of throwing their wards open to female students. If this is done, and if the governors of Anderson's College see their way to the admission of ladies to their classes, the work of the medical education of women, which has so far been confined to Edinburgh (among Scottish schools) might be carried on most successfully in Glasgow.

Inspection of Dead Meat.

The Town Council have determined to ask Parliament for powers for compulsory inspection of all dead meat brought into the city for human food. This is intended to bring foreign and American dead meat under inspection as well as that slaughtered in this country. It is well known that enormous numbers of carcases of oxen and sheep are brought into this country from abroad, and that these escape the inspection to which home-fed carcases are subject.

Public Health.

DURING the fortnight ending Sept. 21st there were registered 375 deaths, as compared with 410 in the preceding fortnight. This represents a death-rate of 18·5 per 1000 living, in place of 20·2 (or 17·5 in place of 19·1, according to the new estimate of the population noted below).

Glasgow, Oct. 1st.

DUBLIN.

(FROM OUR OWN CORRESPONDENT.)

Health of Dublin during 1888.

THE report of Sir Charles Cameron, medical officer of health for Dublin, upon the state of public health in that city during last year has been issued, and is one of great interest and well worthy of perusal. In 1888 the births in the Dublin registration district numbered 9884, or 28 per 1000, the average rate for the preceding ten years being 29; while the deaths amounted to 8894. Omitting 233 deaths of persons admitted into public institutions from places outside the Dublin registration area, the death-rate was 24·5, which was 3·9 below the average. Deaths from the principal zymotic diseases amounted to 983, or 2·8 per 1000 persons living. When we examine the city proper, we find that the total deaths from all causes was 6714, as against 8373 in 1887. The death-rate was equal to 26·22, the rate in 1887 being as high as 33·2. Of zymotic diseases, small-pox caused 1 death, measles 70, as against 423, and typhus fever only 25 deaths. Typhus fever has for some time past seemed to be dying out; whilst, on the other hand, enteric fever was more prevalent than usual during the year, 124 deaths having taken place, or an increase of 29. The most fatal zymotic disease during 1888 was whooping-cough, no less than 221 deaths from it being registered, as contrasted with 143 in the previous year. The greatly lessened mortality of 1888 may be chiefly attributed to a falling off in the number of deaths from zymotic diseases and constitutional maladies. As regards infant mortality, it may be fairly alleged that the high death-rate of towns is chiefly due to an excessive mortality of the children of the poor. Measles and other diseases which are rarely fatal in well-to-do families are formidable diseases in the homes of the very poor. The number of deaths of children uncertified in Dublin is something incredible, and is almost as great as the number in London with its immense population. It is, however, satisfactory to learn that in 1888 there has been a considerable decline in the death-rate among children under five years of age. The infantile death-rate was much greater in Dublin last year, as contrasted with London, both as regards its relation to the number of children under one year of age and the number of births, the latter being the most reliable test of infant mortality in a community. As pointed out by Sir Charles Cameron, the really serious factor affecting the death-rates is age-distribution. If it is identical in two towns, then the death-rate in both should be equal, and, if not equal, then that in which it is higher is clearly the more unhealthy.

Meath Hospital and County Dublin Infirmary.

The winter session of 1889–90 will be inaugurated on Monday next, Oct. 7th, when an introductory address will be delivered in the institution at 10 A.M. by Sir George Porter, Bart., senior surgeon to the hospital. The same evening the annual dinner for the *réunion* of old students, annual and life governors of the hospital, will take place at 7 o'clock at the Shelbourne Hotel. Sir Howard Grubb, F.R.S., one of the governors, will preside. Application for dinner tickets must be made on or before Saturday, Oct. 4th, to the honorary treasurer, Dr. L. Hepenstal Ormsby, 92, Merrion-square West. One or two guests may be invited by each governor or old student. It is expected that this *réunion* will be largely attended, judging from the number of names sent in already to the hon. treasurer by gentlemen intimating their intention to be present.

County Wexford Infirmary.

In consequence of the decease of the late surgeon—Mr. Henry H. Boxwell—a vacancy arose, and the governors last Monday met at the infirmary to elect his successor. There were two candidates; Mr. David Hadden, F.R.C.S., being elected by a majority of votes. The emoluments of the post are £120 per annum and a house.

Dublin, Oct. 1st.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Are Professional Services Obligatory?

IT is generally believed in the profession, at all events throughout England and France, that medical men not engaged in public practice or bound by any contract, are free agents, and at liberty to give, or to decline to give, as may to them seem fit, their professional services. It would be news to most of them to learn that in accepting their diplomas they *ipso facto* undertook to discount their liberty of professional action by engaging to be at the beck and call of public authorities or private individuals whenever these might deem it proper to requisition their skill or expert opinion. That, however, the point is a moot one, at least, so far as France is concerned, is evident from the facts which I am about to relate. The liberty of the subject is questioned, and would even appear to be considered restricted, when the subject happens to be a medical man. Curious as this may sound in the nineteenth century, it is nevertheless true. We all know, and often to our cost, that there are many things touching the affairs of members of our profession about which the law appears to be by no means settled; but not many will be prepared to hear that our freedom of action is one of them. The matter is now being brought to an issue in the town of Rodez, where the relations between the medical practitioners and the local authorities have for the past two years or more been somewhat strained. Many things, which it would be useless for my present purposes to recount, have as time went on tended to render these relations more and

Digitized by Google

more strained, until they finally culminated in the open rupture which has now taken place. On Aug. 25th last the daughter of a farmer of Solsac, in Aveyron, disappeared from her home. Three days afterwards her body was found, and the local authorities were of course immediately on the alert with a view to elucidate the cause of the girl's death. With this object they sought the assistance of the medical men, one after another, in the immediate neighbourhood and the surrounding district, every one of whom, for various reasons which he stated, declined giving his services. The Procureur-Général of Montpellier was then applied to for advice, and he responded by promptly summoning the medical men before the local police-court, founding his charge against them on, as he alleges, the contravention by the doctors of Article 475 of the Penal Code, which runs: "Those who, being able, refuse either to take the necessary precautions, to give the services, or to lend the assistance which may be required of them in times of accident, riot, shipwreck, flood, fire, or other calamity, as well as in cases of brigandage, pillage, *flagrant délit*, public disturbance, or judicial execution, will be liable to a fine of from 6 to 10 francs inclusive." The matter under this heading came before the local court on Sept. 20th, the doctors being represented by the legal adviser to the Medical Society of Aveyron, which took up the defence. This gentleman made an eloquent and learned defence, too long for detailed reproduction here, but the salient points of which may be summarised as follows. He submitted, in the first place, that there was no article in the Code by the terms of which medical men were obliged to respond to the requisitions of the authorities, and that it would be quite an arbitrary proceeding to include the refusal of private medical practitioners as such, to act within the limits of conduct against which by its terms Article 475 was intended to operate. Confining himself to the strict technicality that the doctors were summoned in their capacity as medical men and not as private citizens, he maintained that Article 475 did not apply; it was, he said, rather a question of the assistance which every citizen should lend whatever might be his social position. Moreover, he continued, there was a fundamental difference between the medical man called as a witness to a fact which passed under his eyes, and the medical expert from whom one expected an intellectual effort requiring a special training, experience and care, which effort he made under the solemnity of an oath for remuneration. Furthermore he urged that even in their capacity as citizens Article 475 could not be said to apply, for the article was framed strictly speaking with quite another object in view. In accidents, wrecks, fires, &c., the assistance of every citizen, whatever his position, might perhaps be legally solicited in the emergency, but the case in point was quite another matter which the article did not include. Finally, he submitted that the absence of any mention of medical men in the article showed that it was not intended to apply to them specially, and that it could take no cognisance of the refusal of the doctors to withhold their services if they thought proper. At the end of the legal arguments the court decided to postpone judgment until Oct. 4th. The decision on the question is awaited, as well it may be, with considerable interest in the profession. It is right to add that the medical men make out a strong case of arbitrary treatment and high-handed proceeding against the local authorities for some time past.

The Heating of Parisian Houses.

As the winter approaches the question of the best and most economical way of heating our dwelling-houses comes again to claim attention. In consequence of the dearness of coal in this city its use is debarred to very many people, especially amongst the poorer classes. Wood, which is the alternative in open fire-places, is on the other hand cheaper, but gives out so little heat that, not to speak of the constant attention which it needs, it has to be burned pretty liberally before it will give enough heat to warm sufficiently an ordinary-sized apartment, so that in the result it comes to be almost as dear as coal. People are thus driven to the expedient of adopting the movable stove for heating purposes, of which the number of patterns offered to the public at tempting prices, or on the hire system, is legend, each pattern being warranted to excel the other in perfection and economy of consumption. The use of these stoves is very general already, while it is still on the increase, and *pari passu* with this increase the number of cases of accidental poisoning by carbon monoxide is largely increased, and goes on augmenting. The carelessness and ignorance attending the use of these stoves are so universal and the fatal accidents to be attributed to them so numerous that public attention was drawn to the matter in an able paper read at the Academy of Medicine by Dr. Lancereaux, in which he condemned the use of the movable stove, pointing out the dangers following in its train, and recommending that the State should be asked to regulate and supervise its use. In this sweeping condemnation he was joined by Dr. Brouardel, the well-known medical jurist, and Professor Gautier, the professor of chemistry at the Paris Faculty. Notwithstanding this, the public seems quite as eager as before to secure stoves of this kind, judging by the number of "new and perfect" models which are being constantly puffed in the daily press under fantastic names. There is reason to believe, however, that the authorities, alive to the danger to the public, will soon place the use of these asphyxiators under official control.

The Continental Anglo-American Medical Society.

The first meeting of the Continental Anglo-American Society took place on Monday afternoon, at the Grand Hotel, Sir Spencer Wells, one of the honorary presidents, taking the chair. The business was limited to the election of the officers of the Society, and arranging for next year's meeting. The same evening most of the members dined together in one of the sumptuous banqueting rooms of the Great Caravanserai. To the trivial all things are trivial, but the medical thinker, especially the physician to the dyspeptic millionaire, knows that proper cookery is half the art of medicine. Parisian doctors have, moreover, the well-merited reputation of being accomplished *gourmets*, and it was therefore no small responsibility that the dinner committee assumed in drawing up the *menu* for so critical a body of diners. What arts and seductions were employed have not transpired; but the practical result was that both wines and dishes were unexceptionable—a thing hitherto unknown in the annals (at any rate, of this town) of public banqueting. The task of proposing the health of the Queen and the presidents of the American and French Republics fell to Sir Spencer Wells, who acquitted himself with his customary *finesse*. Dr. Alan Herbert proposed the prosperity of the new Society, and two gentlemen not on the list followed, congratulating everybody generally. Sir Spencer Wells was then toasted, and the honorary secretary, Dr. Linn, also came in for a very well-deserved share of the honours. The speech of the evening, however, was that of Dr. Worms, who spoke as follows:—"Gentlemen, the French physicians whom you have been kind enough to ask to your cordial meeting have entrusted me with the agreeable mission of thanking you for your kind hospitality and of drinking to the prosperity of your association and its members. There exists between English and American *confrères* a bond of blood and language, and it is in the nature of things that they should consider themselves as brothers, and walk hand in hand in the path of science and in medical practice. The future of your association finds already in these conditions a guarantee of success; but I think also, gentlemen, that in this great city of Paris our English and American *confrères* find the greatest liberty for the development of their professional activity, and that they will never meet with any impediment either from their own compatriots or from us. I believe that I am expressing exactly the thoughts of French physicians, the present as well as the absent, in offering you on their behalf a greeting of cordial confraternity, to which is added a feeling of sincere friendship. French medicine has manifested to several of your number, gentlemen, its affection and its gratitude. I could cite several names, but you must allow me only to mention our illustrious president, Sir Spencer Wells, with whom I have been united in friendship for more than thirty years, and to whom I owe the honour of being amongst you. The name of Sir Spencer Wells is most popular in France, and most respected, and his election to the Academy of Medicine was the proof of this unanimous feeling. This sentiment has its origin in the incomparable services he has rendered to French surgery. It is to his loyal practice, open to all, that Sir Spencer Wells owes the definite acceptation of the operation of ovariotomy in France. That is his title to fame here, and that is why he has merited the gratitude and admiration of my countrymen."

Paris, Oct. 1st.

Obituary.

COMMENDATORE PIETRO DURANTI.

ON the morning of the 27th ult. the Pisan School of Medicine lost one of its brightest ornaments by the death of Dr. Pietro Duranti, professor emeritus in the University. He formed one of its teaching staff in 1851. He was director of the anatomical theatre, dissecting-rooms, and laboratory, and subsequently dean of the medical faculty, in which he held for many years, with much acceptance, the post of professor of surgery, theoretical and clinical. He was also a prominent member of the Academic Council, and in his appointment as Rector of the University he enjoyed and did justice to the highest honour the school could confer. To quote a Tuscan correspondent, "he was respected and admired for his learning and teaching power, while he was beloved for his sterling virtues and his kindly manners by colleagues, students, and citizens alike. He held numerous honorary posts and distinctions, Italian and foreign, and at the time of his death he was the working president of the Royal Conservatory of Sant' Anna, which owed much to his energy, his intelligence, and his accomplishments." Years of still further usefulness seemed in store for him, when he was struck down very suddenly at the age of seventy-four.

Medical News.

THE ALLEGED LEAD-POISONING AT KEIGHLEY WORKHOUSE.—On Monday an inspector from the Local Government Board made a private inquiry at the workhouse, with regard to the large number of inmates who, it is stated, are suffering from lead-poisoning.

EPSOM COLLEGE: FEMALE ORPHANS.—The Council of the Royal Medical Benevolent College will shortly elect an orphan daughter of a medical man to a scholarship giving free education and maintenance at the school of St. Anne's Society. Particulars will be found in our advertising columns.

THE PASTEUR INSTITUTE.—On the 2nd inst. three more patients—a man and two boys—who had been bitten by a rabid dog at Rugby, were sent to Paris to be treated at the Institut Pasteur at the expense of the Lord Mayor's Fund. This makes a total of twenty-eight persons sent from that source during the last three months.

WEXFORD INFIRMARY.—By the will of Mr. D. Cullimore, late of Longford-terrace, Monkstown, county Dublin, and of Ballyanne Park, county Wexford, and uncle to Dr. Cullimore, of Welbeck-street, W., the Wexford Infirmary has been left over £1000, and the poor of the village of Taghmon, county Wexford, over £8000.

RABIES.—The number of dogs in England officially reported during the week ending Sept. 21st as afflicted with rabies was 6, against 8 in the previous week; of these, 5 were killed and one died. The distribution was as follows:—York (West Riding) 2, and Chester, Kent, Lancaster, and Sussex, 1 each. No cases were reported from London.

HARROGATE BATH HOSPITAL.—This institution is now open for the reception of patients. The committee of management have made energetic efforts to extend the usefulness of the charity, and are making a special appeal for funds to liquidate the debt remaining on the building, which amounts to £10,000. The charity is open to the indigent poor throughout the United Kingdom.

POLICE SURGEONS IN CASES OF MURDER AND MANSLAUGHTER.—A memorandum has been sent to the divisional surgeons of the Metropolitan police, by the direction of the Commissioner, requesting them in all cases of murder or manslaughter to send a report of their post-mortem examination and conclusions as to the cause of death to the Commissioner, "as experience has shown the necessity and great importance of the police having the earliest possible information as to the medical examinations in such cases."

THE DWELLINGS OF THE POOR.—A meeting of the Mansion House Council on the Dwellings of the Poor, of which the Lord Mayor is president, was held on the 2nd inst., in the Long Parlour. Mr. John Hamer (hon. secretary) stated that the Grand Prize had been awarded to the Council by the jurors of the Paris Exhibition. Action in regard to insanitary dwellings had been taken in Finsbury, Marylebone, Shoreditch, Mile-end, Plumstead, and St. Saviour. In Bermondsey and Greenwich revisits of insanitary conditions were reported as having been satisfactory, inasmuch as complete remedies had been applied to the nuisances.

THE LOWESTOFT HOSPITAL.—The annual meeting of the governors of this hospital was held last week. The report, which was adopted, stated that the financial position of the institution was unsatisfactory and demanded the consideration of all interested in the charity. There had been during the past year a considerable decrease in the annual subscriptions, donations, and the proceeds of the Hospital Saturday Fund. The balance sheet showed a deficit of £250 17*s*. The present income from funded capital and other reliable sources amounted to £1000 per annum, and the expenditure, controlled with economy, to £1250. The number of patients treated had exceeded that of any previous year, being, in-patients 235, and out-patients 1330.

FIFESHIRE MEDICAL ASSOCIATION.—Last week the annual meeting of this Association was held at Dunfermline. Mr. James Morris, F.F.P.S. Glas., of Dunfermline, the president, read a paper on "Chloroform and other aids in Midwifery Practice." He stated that during the past seven years he had attended 570 cases, and in the majority of these had used chloroform, the effect of which was that only one mother out of that number had died, and four of the children were stillborn. This result was highly satisfactory, inasmuch as the average death-rate was from 1 to 2 per cent., while with children the average was from 5 to 10 per cent. Similar experiences were given by other practitioners. The officer-bearers were elected for the ensuing year, and the meeting terminated.

FOOTBALL CASUALTIES.—William Mundin, on the 21st ult., whilst playing in a football match at the Central Park, Aberdeen, between the Orion and Black Diamonds Clubs, fell and broke his collar-bone. A few weeks since he, during a football match in the same place, had his right arm dislocated. At a return league football match, on the 30th ult., between Everton and the Wolverhampton Wanderers, a young man named Allen sustained a sprained ankle. On Saturday last, during a match played under the Association rules at Heywood, a young man named Ashworth fell violently to the ground, and was badly injured in his spine. A youth named Hopton, who was injured in a football match at Newport, Monmouth, on Saturday, died in the Infirmary on Monday morning. On Saturday, a boy named Murray, ten years of age, fell down dead whilst playing football with other boys at Preston. He had just scored a goal.

METROPOLITAN ASYLUMS BOARD.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.*

BAYLEY, R. L., L.R.C.P. Lond., M.R.C.S., L.S.A., has been reappointed Medical Officer, Oldswinford Second District, Stourbridge Union.

CAMERON, J. S., M.D. Edin., M.R.C.S., has been appointed Medical Officer of Health for the Borough of Leeds.

CAMPBELL, ALFRED W., M.B., C.M. Edin., late Temporary Assistant Medical Officer, Norfolk County Asylum, Thorpe, near Norwich, has been appointed Junior Assistant Medical Officer to the County Asylum, Bicton Heath, Shrewsbury.

D'ARCY, SAMUEL ALGERNON, L.K.Q.C.P. Irel., L.R.C.S. Irel., L.M.R., &c., has been appointed Assistant Master of the National Lying-in Hospital, Dublin.

FARRINGTON, JOHN, M.R.C.S., L.R.C.P., has been appointed House Surgeon to the Pendleton Branch Dispensary of the Salford Hospital.

FRASER, D. A., M.D. Brussels, M.R.C.S., L.S.A., has been appointed Medical Officer and Public Vaccinator of Berry Pomeroy, Littlehempston and Stoke Gabriel, Totnes Union.

GARDNER, ERNEST FREDK., L.R.C.P., M.R.C.S., has been appointed House Surgeon to the Evelina Hospital for Sick Children, vice G. H. Pennell, resigned.

HAINS, L. I. C., L.R.C.P., L.R.C.S. Edin., has been appointed Medical Officer and Public Vaccinator of Totnes and Darlington, Totnes Union, vice Raby, resigned.

HOFFMEISTER, WILLIAM, M.D. Heidelb., L.R.C.P. Lond., M.R.C.S., has been reappointed Medical Officer of Cowes Port Sanitary Authority, Isle of Wight.

HOLDEN, G. H. R., M.A., M.B., B.C. Cantab., M.R.C.S., L.R.C.P. Lond., has been appointed House Surgeon to St. Bartholomew's Hospital.

LOMAS, ERNEST C., M.B., Ch.B. Vict., M.R.C.S., has been appointed Senior House Surgeon to the Royal Albert Edward Infirmary, Wigan, vice A. J. Barnard, M.R.C.S., L.R.C.P. Edin., resigned.

MACKINTOSH, DONALD J., M.B., C.M., has been appointed Superintendent and Resident Medical Officer of the Victoria Infirmary, Glasgow.

MCDOUGALL, W. STEWART, M.B., C.M. Edin., has been appointed Assistant House Surgeon to the Cumberland Infirmary, Carlisle, vice T. C. Meikle, M.B., C.M. Edin., resigned.

OGLESBY, H. A., L.R.C.P. Edin., L.M., M.R.C.S., has been appointed Medical Officer, York Union District.

RUTHERFORD, W. G., L.R.C.S., L.M., L.K.Q.C.P. Irel., has been appointed Medical Officer of the Seventh District, Newport Pagnell Union.

SHAW, CECIL E., M.A., M.D., M.Ch., of Belfast, has been appointed Honorary Consulting Ophthalmic Surgeon to the Alexandra Hospital, Ballymena.

STAMFORD, W. A., M.R.C.S., has been reappointed Medical Officer of the Sixth District, Mansfield Union.

STEVENSON, LOUIS E., B.A., M.B., B.C. Cantab., has been appointed House Surgeon to the Cumberland Infirmary, Carlisle, vice J. F. Haswell, M.B., C.M. Edin., resigned.

STYLE, F. W., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer of Health for Hucknall Huthwaite, vice T. Shaw, resigned.

TEW, JAS. SCOTT, M.B., B.S. Durh., D.P.H. Camb., has been appointed to the Basford Union Rural Sanitary District, vice P. Boobbyer, appointed to Nottingham.

THRING, EDWARD T., F.R.C.S. Eng., has been appointed Assistant Obstetric Surgeon to the Prince Alfred Hospital, Sydney, and Surgeon to the Children's Hospital, Lewisham, Sydney.

WADE, CHARLES, L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer of Health and Public Vaccinator to the Boscastle District of the Camelford Union, vice Arthur Wade, resigned.

WALLIS, FRED. C., B.A., M.B., B.S. Cantab., M.R.C.S., has been appointed Demonstrator of Anatomy at Charing-cross Hospital.

WEARY, GEORGE E., M.R.C.S., L.R.C.P. Lond., has been appointed Resident Medical Officer of the Boscombe Hospital and Provident Dispensary, Boscombe, Bournemouth.

WETWAN, WM. ALBERT, M.R.C.S., L.S.A., has been appointed Certifying Factory Surgeon for the Bridlington District, vice C. F. Hutchinson, M.D., deceased.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement.

CLAYTON HOSPITAL AND GENERAL DISPENSARY, Wakefield.—House Surgeon. Salary £120 per annum, with residence at the hospital, attendance, coals and gas.

DORSET COUNTY ASYLUM.—Assistant Medical Officer. Salary £120 per annum, with board and residence.

GATESHEAD DISPENSARY.—Resident House Surgeon. Salary £200 per annum, with furnished apartments in the dispensary, coals and gas.

GENERAL DISPENSARY AND INFIRMARY, Jersey.—Resident Medical Officer. Salary £120 a year, with furnished apartments and attendance.

GENERAL INFIRMARY AT LEEDS.—Resident Obstetric Officer. House Physician. House Surgeons. These appointments for twelve months.

HANTS COUNTY ASYLUM, Knowle, Fareham.—Junior Assistant Medical Officer. Salary £100 per annum, with furnished apartments, board, washing, and attendance.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, London, W.C.—Resident Medical Officer as House Surgeon, for one year. Salary £50 per annum, with board and residence in the hospital.

LANCASHIRE COUNTY ASYLUM, Rainhill, near Liverpool.—Assistant Medical Officer. Salary commencing at £105 per annum, with furnished apartments, board, attendance, and washing.

LIVERPOOL INFIRMARY FOR CHILDREN, Myrtle-street.—House Surgeon. Salary £85 per annum, with board and lodging.

LONDON LOCK HOSPITAL AND ASYLUM, Harrow-road and Dean-street, W.—Physician and Surgeon to Out-patients.

OWENS COLLEGE, Manchester.—Junior Demonstrator in Physiology. Salary £100 per annum.

PADDINGTON-GREEN CHILDREN'S HOSPITAL, London, W.—House Surgeon. Salary £50 per annum, with board and residence. Appointment for six months.

ROYAL PORTSMOUTH, PORTSEA, AND GOSPORT HOSPITAL.—House Surgeon for one year. Salary £70 per annum, with board and residence. Also Assistant House Surgeon for one year. No salary, but board and residence provided.

SHEFFIELD GENERAL INFIRMARY.—House Surgeon. Salary £120 per annum, with board, lodging, and washing, with a prospective advance of £10 per year for the second and third years. Also Assistant House Surgeon. Salary £80 per annum, with board, lodging, and washing. These Appointments to continue for three years only.

STOKESLEY UNION, Stokesley.—Medical Officer for the Union Workhouse and the Stokesley district. Salary £54, exclusive of vaccination fees, and such extra medical fees as are allowed by the Local Government Board.

UNIVERSITY COLLEGE, Dundee.—Professor of Physiology. Salary £350 per annum, with two-thirds of the fees.

WESTERN GENERAL DISPENSARY, Marylebone-road, N.W.—Honorary Dental Surgeon.—Also Honorary Surgeon.

Births, Marriages, and Deaths.

BIRTHS.

BOSWELL.—On Sept. 21st, at Saffron Walden, the wife of Henry St. G. Boswell, M.B., of a son.

CARPENTER.—On Sept. 28th, at Wykeham House, Bedford-park, Croydon, the wife of Arthur B. Carpenter, M.B. Oxon., of a daughter.

DAWSON.—On Sept. 27th, at Heathlands, Southbourne-on-Sea, the wife of Yelverton Dawson, M.D., of a son.

MOODIE.—On Sept. 25th, at Park Avenue House, Stirling, the wife of Robert Moodie, M.D., B.Sc., of a son.

WEBSTER.—On Sept. 27th, at Wribbenhall, Bewdley, the wife of George L. Webster, M.R.C.S., of a son.

WREFORD.—On Sept. 30th, at 260, Clapham-road, the wife of Samuel Wreford, M.R.C.S., of a daughter.

MARRIAGES.

ARNOLD—MAYHEW.—On Oct. 1st, at St. Mary's, Walmer, Samuel Carnelley Arnold, M.B., C.M. Edin., of Minster, Thanet, to Emsie, second daughter of the late Thos. Mayhew, Esq., of Sevenscores, Minster.

BAREFOOT—WALKER.—On Oct. 2nd, at Christ Church, Southport, by the Ven. Archdeacon Clarke, John Richard Barefoot, surgeon, Army Medical Staff, to Lilian Elizabeth Mary, daughter of Henry Walker, Esq., of Mosborough Hall, Derbyshire, and Southport.

BATTAMS—HART.—On Sept. 28th, at the Parish Church, Hornsey, James Scott Battams, M.R.C.S., of 123, Lavender-hill, S.W., late Resident Medical Officer, East London Hospital for Children, to Kate Elizabeth, daughter of the late George Hart, of Wakefield, Yorkshire.

HALES—WARD.—On Sept. 26th, at Christ Church, Gailey, Robert Turner Hales, M.D., son of John Hales, Esq., of Holt, Norfolk, to Alice Mary, third daughter of Henry Ward, Esq., of Rodbaston, Stafford.

HODSDON—RAFFIN.—On Oct. 2nd, at Dornster House, Mayfield-gardens, Edinburgh, by the Rev. W. M. Falconer, M.A., and the Rev. George Davidson, M.A., James W. B. Hodsdon, M.D., F.R.C.S. Edin., to Joan, daughter of the late William Raffin.

MAYLARD—REDDIE.—On Oct. 2nd, at St. Silas's English Episcopal Church, Glasgow, by the Rev. Sholto D. C. Douglas, M.A., Incumbent, assisted by the Rev. T. M. Macdonald, Canon of Lincoln and Rector of Kersal, Manchester, Alfred Ernest Maylard to Jane, elder daughter of Charles Reddie, of Glasgow, and granddaughter of Sir George Burns, Bart., of Wemyss Bay.

MORRISON—TITTERTON.—On Sept. 27th, at the Central Hall, Great Charles-street, Birmingham, by John Morrison, LL.B., brother of the bridegroom, James Thos. Jackman Morrison, M.A., B.C. Cantab., F.R.C.S. Eng., of Birmingham, to Edith Mary, eldest daughter of the late John Ward Titterton, of The Manor, Shifnal, Salop, and niece of Sir Charles B. H. Soame, Bart.

THOMAS—SCOTT.—On Sept. 21st, at St. Matthew's Church, Gosport, William Thomas, M.R.C.S., L.R.C.P., &c., of Rhyl, to Elizabeth Mary, only daughter of W. Scott, Esq., of the Royal Clarence Yard, Gosport.

VACHER—BLECKLEY.—On Oct. 2nd, at St. Andrew's Church, Birkenhead, by the Rev. A. McLeod, D.D., assisted by the Rev. A. M. Symington, D.D., Francis Vacher, F.R.C.S., to Elinor Margaret, daughter of the late Rev. John Mollan Bleckley, A.B., of Wicklow.

DEATHS.

BLUNT.—On Sept. 25th, at St. Martin's, Leicester, Thomas Blunt, M.D., aged 47.

SMITH.—On Sept. 29th, at Park-street, Grosvenor-square, Protheroe Smith, M.D., in his 80th year.

VASSIE.—On Sept. 25th, at Crofton Hill, Lanark, Richard Vassie, M.D. Edin., M.R.C.S., late of Kirkcaldy.

WILLS.—On Sept. 28th, at Orleigh Mount, Torquay, William Wills, M.R.C.S., father of the late Wm. John Wills, Australian Explorer, aged 85.

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editors."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed to the Sub-Editor.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "to the Publisher."*

We cannot undertake to return MSS. not used.

HEREDITY OF BONE DISEASE.

JULIUS DOLLINGER of Buda-Pesth has been trying to discover what influence the health of grandparents has upon the tendency to bone and joint tubercular disease in the grandchildren. He has, of course, met with great difficulty; and in the poorer classes, among whom these diseases are most common, patients are often quite unable to give any reliable information as to their grandparents. But his investigations have led him to the conclusion that bone and joint tubercle is found more often in the grandchildren than in the children of those who suffer from pulmonary tuberculosis.

Mr. T. A. Papillon.—The article appeared in THE LANCET of Sept. 29th, 1888, p. 628. Probably Dr. Weigert of Berlin could give further information.

PHYSICAL DEVELOPMENT.

To the Editors of THE LANCET.

SIRS,—Two years ago you courteously published the paper I read on the experimental production of chest types in man. Thanks to the cordial co-operation of Mr. J. E. K. Studd and the Polytechnic authorities, we a few months ago inaugurated a society to practically apply the principles laid down in that paper, and the results have been both so successful and of so much importance that I shall be glad if you will enable me to place them before the profession.

The society already numbers upwards of sixty members, and a fair sample of their measurements—thirty—now lies before me. I find the chest-girth has increased on an average one inch and a half, the range of movement over an inch, and in one-third of the cases the chest-girth has increased from two inches to three inches and three-quarters. These changes have been effected as easily in a chest of thirty-six or thirty-eight inches as in one of thirty or thirty-two inches, and that irrespective of the height. Some of the members are between twenty and thirty years of age, and have had gymnastic and athletic training. Amongst them are clerks, printers, carpenters, tailors, grocers, &c., and they are engaged in their occupations many hours daily. Consequently, the practicability of obtaining a very considerable increase of the chest-girth and the many great advantages that implies is now unquestionably established. We obtained these results by very simple means. The conditions, habits, and surroundings that tend to reduce the breathing capacity were removed or compensated for, conditions, habits, and surroundings that tend to develop the chest were introduced, and the measure of the success with which that was effected is seen in the extent of the increase each member obtained. And I need only point out the immense importance of true physical development in the education of children, in the training of soldiers, and for life assurance, in order to justify an earnest plea for the co-operation of the profession in urging its general adoption.—Yours faithfully,

G. W. HAMBLETON,
President, Polytechnic Phys. Develop. Soc.;
Memb. Occupations Committee.

Dorchester-place.

A BICEPHALOUS MONSTROSITY.

TOWARDS the end of last month a woman gave birth, at Sestri Ponente on the North Italian Riviera, to a fœtus, weighing 1990 grammes, having two distinct heads, two thoracic and two abdominal, extremities quite normal and well-developed—the thoracic being 12 centimetres in length, and the abdominal the same. Both the heads are covered with longish black hair, and reveal, to the touch, large sutures and fontanelles; in both, moreover, the eyes are well-pronounced, with the pupillary membranes distinguishable. One head has a double hare-lip, the fissure towards the left side being the deeper. The same head has an occipito-frontal periphery of 26 centimetres, while that of the other measures 24. The shoulders are covered abundantly with a fine *lanugo*. The smaller head resembles a large fungus with its peduncle planted on the epigastric region of the fœtal body; it is seen, lower down, with the face on the anterior superficies of the neck, as if in the act of kissing, and as if embraced by the thoracic extremities. The abdomen is open in such a way as to render visible the liver, the spleen, the kidneys, and the intestinal mass, while its parietes are extremely thin. Parturition was very laborious, but Dr. G. Tubino, the obstetric physician who had charge of the case, was able to tide the mother over all difficulties, so that she is now in good health. The monstrosity, skilfully preserved, is now on view in the Museo Ostetrico of the Medical School of Genoa.

W. G. E.—Probably FitzWygram on the Horse, and Courtenay's Manual of Veterinary Medicine and Surgery, would be found to answer our correspondent's purpose.

M.B., B.S.—The card is in good taste.

ATTENDANCE ON MEDICAL MEN'S FAMILIES.

To the Editors of THE LANCET.

SIRS,—"An Old Subscriber" has ventilated a grievance of long standing from his point of view, in which he has my hearty sympathy. Allow me to put forward another aspect of the case, from the consultant's point of view.

I am certain that every consultant has pleasure in giving advice gratuitously to his brethren and their families so long as the latter are dependent upon their fathers. The obligation ought, however, to cease when sons are started in life and when daughters are comfortably married. There should, I think, be a delicacy, too, in demanding the aid of a perfect stranger, and perhaps saddling him with an operation and long attendance, when other consultants to whom the sufferer is well known would be able to afford equally capable assistance. But it is of the unreasonable use of telegrams when letters would fulfil every purpose that I complain. A telegram is supposed to mean *urgency*, and it is somewhat trying when one has thrown up other engagements to obey a telegraphic summons to find the doctor out, and to learn that one is not expected. Your correspondent complains rightly of discourteous want of letter-writing. I cannot tell how often I ask a medical man to let me know the after-progress of a case I have seen with him, but I know that the answers are few and far between. Even invitations to dinner are left unanswered for many days, notwithstanding that "an early answer is requested."

I am, Sirs, yours obediently,

September, 1889. A CONSULTANT.

THE JONES FUND.

MR. WILLIAM JONES, L.R.C.P., returns many thanks to those gentlemen who subscribed towards his indemnity fund, and also to Dr. Hunt for the trouble he has taken and the sympathy he expressed.

Alpha.—The Births and Deaths Registration Act of 1874 enacts in Section 48 that the chief resident officer of every public institution shall be deemed to be the occupier of such dwelling, and as such he is bound to act as informant of such death, if no better qualified informant can be obtained. Registrars of births and deaths, however, are specially instructed that in the case of a death in a public institution they should, whenever practicable, obtain the necessary information from a relative of the deceased.

Mr. J. Thomas is not entitled to a fee.

ANTIPYRIN AND SODIUM SALICYLATE.

To the Editors of THE LANCET.

SIRS,—In reply to Dr. Monteith's letter regarding the pasty compound which results when antipyrin and sodium salicylate are mixed together, I may state that two French pharmacists, Prudhomme and Vigur, have investigated the matter, and their results show (see *The Chemist and Druggist*, vol. xxxiv., p. 830) that a solution of antipyrin and the salicylate does not undergo change, and may be preserved indefinitely. Whether the paste or syrup formed when the substances are mixed in the dry state is a new compound or not has not been proved, but I believe that the change is similar to what takes place when chloral and camphor are mixed. The powders do not liquefy, on account of absorption of moisture from the air. I may say that pharmacists are familiar with the change, and when they have an opportunity bring the fact under the notice of prescribers.

I am, Sirs, yours faithfully,

Cannon-street, E.C., Sept. 27th, 1889. PETER MACEWAN.

MICRO-ORGANISMS IN CHEESE.

PROF. ADAMETZ, of the School of Cheese-manufacture at Sornthal in Switzerland, in the course of his investigations into "caseous pathology," has succeeded in isolating no fewer than nineteen species of microbes in one kind of cheese, and that in the fresh state. For every gramme of this he found bacteria numbering from 90,000 to 140,000, and these multiplied to more than 800,000 in a seventy-days' cheese. In the soft cheese the microbes were still more numerous. Prof. Adametz found 1,200,000 in one gramme of a thirty-four days' cheese, and 2,000,000 in a forty-five days' specimen. These were found in the interior parts of the cheese. On the rim he calculated there were from three to five millions for every gramme. By a series of ingenious experiments the same pathologist demonstrated that the arrest by antiseptic substances of these micro-organisms prevents the cheese from maturing.

Dr. T. P. Atkinson.—We think it reasonable that the officer in question should receive the fee, as provided in the Act.

VENTRO-FIXATION OF THE UTERUS.—MEDICAL FEES IN LIFE ASSURANCE.

To the Editors of THE LANCET.

SIRS,—In one of your annotations in to-day's issue is a quotation from a lecture by Dr. Thiriar of Brussels on the above subject, in which he speaks of the operation as a new one. I think it right, therefore, to say, if only for the credit of my country, that I performed this operation successfully (and purposely not taking it in connexion with ovariotomy) as long ago as 1880, at the Hospital for Women. I used a silk suture in picking up the fundus uteri, and silkworm gut to close the abdominal wound.

In another annotation in the same number reference is made to a letter at page 677 on the subject of medical fees in life assurance. Did "G. F. H." write to the insurance company in question? I think it but fair to state that the Prudential Assurance Co. sent me half a guinea the other day as a fee for reporting on the life of one of my patients, but on my representing that the usual fee was one guinea they at once sent it to me.

I am, Sirs, yours faithfully,

Harley-street, Sept. 28th, 1889. HEYWOOD SMITH.

"A CAUTION."

To the Editors of THE LANCET.

SIRS,—In your valued journal of Aug. 10th, 1889, just to hand by mail of Sept. 7th, I see the letter signed by my father. I deeply regret that anyone should use my name to obtain money, and that surgeons attached to St. Thomas's Hospital (my old school) should have been annoyed by these applications for aid. I am proud to remark they know me, in the instances brought to my knowledge, too well to have been defrauded. I sincerely trust no fellow-student nor any of my hospital friends have been imposed upon. Anyone having letters from the impostor would greatly oblige by sending them to the solicitor named in my father's letter (Basil Greenfield, Esq., 31, Nicholas-lane, E.C.). I am the only James Henry Clark on the Medical Register in this country. For the last twenty years no other James Henry Clark has been in practice here, nor in the Medical Service. I was in England for a few months only in 1883. Am in active practice here.

I am, Sirs, yours faithfully,

JAMES HENRY CLARK,

Jamaica, West Indies, Sept. 9th, 1889. Government Medical Service.

FOREIGN BODIES IN THE EYE.

To the Editors of THE LANCET.

SIRS,—Will you kindly correct two errors which were overlooked in the proof of my lecture published last week? I am made to say that a piece of iron or steel "one or two grains in weight," when lying close under the sclerotic, will deflect the magnetic needle. It should be six or seven grains. Also, in the third line of the lecture, the word "forming" should have been *foreign*.

I am, Sirs, yours faithfully,

Newcastle-on-Tyne, Oct. 2nd, 1889. C. S. JEAFFRESON.

RESECTION OF CERVICAL VERTEBRÆ FOR PARAPLEGIA.

To the Editors of THE LANCET.

SIRS,—With reference to the case of resection of the cervical vertebræ &c. for paraplegia, recorded in THE LANCET of Aug. 17th, 1889, page 315, I have pleasure in stating that so completely has the boy recovered that he not only runs about like other boys, but on Sunday last was seen engaged in a stand-up fight with another street arab.

I am, Sirs, yours very truly,

HENRY THOMPSON,

Hull, Sept. 28th, 1889. Surgeon to the Hull Royal Infirmary.

MEDICAL FEES AT CORONERS' COURTS.

To the Editors of THE LANCET.

SIRS,—Can any of your readers inform me what is most usually done with fees for evidence given in coroners' or other courts when these fees are earned by the assistant? Does the assistant take them? or are they divided between principal and assistant? or does the principal appropriate them entirely?

I am, Sirs, yours faithfully,

Sept. 17th, 1889. X. Y. Z.

THE MEDICAL SCIENCE OF THE ANCIENT EGYPTIANS.

IT would appear from an article by Prof. Hirschberg of Berlin, in the last number of the *Deutsche Medizinische Wochen. Chronik* that a great service has been rendered to the science of medicine by the German writer of fiction, George Ebers. Prof. Hirschberg points out that medicine is indebted to that celebrated writer and Egyptologist for the first real insight into the therapeutics of the ancient Egyptians. He has in that respect not only discovered the most important work (Papyrus Ebers), and published a facsimile of it, but has also just rewritten, translated, and provided with comments and illustration one of the most important sections of that Papyrus. The difficulties, Prof. Hirschberg says, were immense; for even if one had read the letter of the name of an illness or remedy, the question arose how to discover the literal meaning and the medical sense of that letter. But as great as was the difficulty is the advantage derived for the history of medical science. According to George Ebers, his MS. is the hermetic book of the medicaments mentioned by Clement of Alexandria. The MS. was certainly written during the eighteenth dynasty about 1500 years before Christ, at the latest. It is a compilation in which very old and some foreign prescriptions were likewise embodied. Thanks to the excellent translation of, and comments upon, the section of the Papyrus Ebers treating of eye diseases, the medical man is now able comfortably to read this oldest book on medical science, which was written a thousand years before Hippocrates.

H. S. has forgotten to enclose his card.

ABNORMAL EFFECTS OF ANTIPYRETICS.

To the Editors of THE LANCET.

SIRS,—In connexion with Professor Heuchen's observations on the abnormal effects of antipyretics in some instances, commented on in an annotation in your issue of Sept. 14th (page 553), I beg to call attention to the following case. E. P——, between sixty-five and seventy years of age, presents the following peculiar idiosyncrasy to quinine: Whenever she takes a grain of the drug it produces elevation of temperature (104° to 105° an hour after the dose), acceleration of pulse and breathing, rigors, slight delirium, nervous disturbance, thirst, dry parched tongue, and hot dry skin, with general malaise and every appearance of ill-defined fever. These symptoms pass off in from twelve to twenty-four hours, leaving the patient quite well. Similar symptoms have occurred three or four times in the same patient at intervals of some months, and in each instance within an hour or so after the dose of quinine.

I am, Sirs, yours faithfully,

Manchester, Sept. 18th, 1889. LEONARD G. PETERS, L.R.C.P., &c.

A WARNING.

To the Editors of THE LANCET.

SIRS,—Waiting-room tables rarely exhibit works of value; or should not, at any rate. A few antique *Punches*, semi-religious circulars, or quasi-puffs, if the practitioner specialises. But inasmuch as the waiting-room is in nine cases out of ten the centre of the medico's abode, let him be careful what he leaves out on his table overnight after a "read." Within a year I have lost a copy of the Æneid (1672), a valuable work in Japanese, and one on Eastern armour, which I should much like to see again, as my name and address will be found in each. I regret to say I remember that I did not put them back in my library after use.

I am, Sirs, yours faithfully,

Wimpole-street. F.R.C.S.

Medical Diary for the ensuing Week.

Monday, October 7.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations, daily at 10 A.M.
ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1.30 P.M., and each day at the same hour.
CHELSEA HOSPITAL FOR WOMEN.—Operations, 2.30 P.M.; Thursday, 2.30.
ST. MARK'S HOSPITAL.—Operations, 2.30 P.M.; Tuesday, 2.30 P.M.
HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M., and on Thursday at the same hour.
METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.
ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.
CENTRAL LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M., and each day in the week at the same hour.
UNIVERSITY COLLEGE HOSPITAL.—Ear and Throat Department, 9 A.M.; Thursday, 9 A.M.

Tuesday, October 8.

GUY'S HOSPITAL.—Operations, 1.30 P.M., and on Friday at the same hour. Ophthalmic Operations on Monday at 1.30 and Thursday at 2 P.M.
ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 4 P.M.; Friday, 2 P.M.
CANCER HOSPITAL, BROMPTON.—Operations, 2 P.M.; Saturday, 2 P.M.
WESTMINSTER HOSPITAL.—Operations, 2 P.M.
WEST LONDON HOSPITAL.—Operations, 2.30 P.M.
ST. MARY'S HOSPITAL.—Operations, 1.30 P.M. Consultations, Monday, 2.30 P.M. Skin Department, Monday and Thursday, 9.30 A.M. Throat Department, Tuesdays and Fridays, 1.30 P.M. Electro-therapeutics, same days, 2 P.M.

Wednesday, October 9.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 10 A.M.
MIDDLESEX HOSPITAL.—Operations, 1 P.M.
ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour. Ophthalmic Operations, Tuesday and Thursday, 1.30 P.M. Surgical Consultations, Thursday, 1.30 P.M.
ST. THOMAS'S HOSPITAL.—Operations 1.30 P.M.; Saturday, same hour.
LONDON HOSPITAL.—Operations, 2 P.M. Thursday & Saturday, same hour.
SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN.—Operations, 2.30 P.M.
GREAT NORTHERN CENTRAL HOSPITAL.—Operations, 2 P.M.
UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.; Skin Department, 1.45 P.M.; Saturday, 9.15 A.M.
ROYAL FREE HOSPITAL.—Operations, 2 P.M., and on Saturday.
KING'S COLLEGE HOSPITAL.—Operations, 3 to 4 P.M.; Friday, 2 P.M.; Saturday, 1 P.M.
CHILDREN'S HOSPITAL, GREAT ORMOND-STREET.—Operations, 9.30 A.M.; Surgical Visits on Wednesday and Saturday at 9.15 A.M.
HUNTERIAN SOCIETY.—8 P.M. The President: A Short Address.—Dr. Turner: Two cases treated by Forced Feeding.
ROYAL MICROSCOPICAL SOCIETY.—8 P.M. Ordinary Meeting.
BRITISH GYNÆCOLOGICAL SOCIETY.—8.30 P.M. Specimens will be shown by Mr. Lawson Tait, Dr. Bantock, Dr. Edis, Dr. R. T. Smith, and others. Adjourned discussion upon Dr. Dolan's paper on Gynæcological Specialism and General Practice. Council Meeting at 8 P.M.

Thursday, October 10.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M. Surgical Consultations, Wednesday, 1.30 P.M. Ophthalmic Operations, Friday, 1.30 P.M.
CHARING-CROSS HOSPITAL.—Operations, 2 P.M.
UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.; Ear and Throat Department, 9 A.M.

Friday, October 11.

ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.

Saturday, October 12.

MIDDLESEX HOSPITAL.—Operations, 2 P.M.
UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.; and Skin Department, 9.15 A.M.

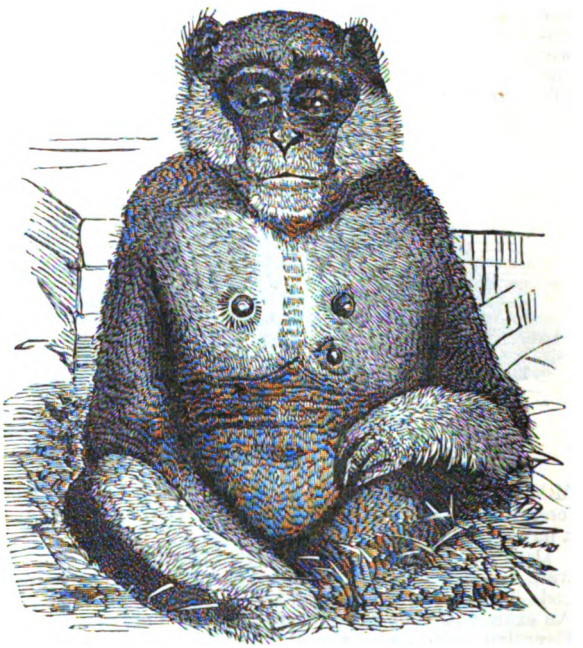
Introductory Address
ON
INTELLECTUAL BLINDNESS.

Delivered at the Middlesex Hospital at the opening of the Session, October 1st, 1889.



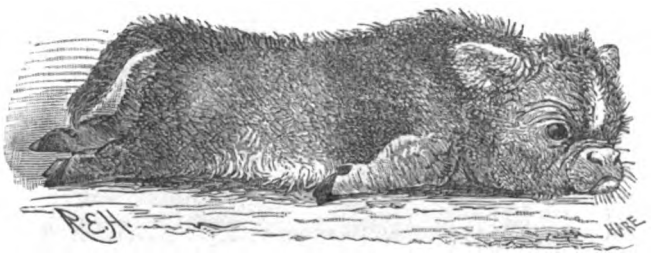
BY J. BLAND SUTTON, F.R.C.S.,
ASSISTANT SURGEON TO THE HOSPITAL.

GENTLEMEN,—To-day I shall speak of a widespread and important defect known as Intellectual Blindness. We shall limit our attention on the present occasion to its two most important forms—blindness in observation and blindness in interpretation. The subject is one worthy our most anxious consideration, for rest assured the success with which we practise medicine and surgery rests in a large measure upon the means with which we endeavour to combat the insidious attacks of this form of blindness. I cannot too strongly impress upon you the importance of observation, seeing that in medicine we adopt essentially the Baconian method, and depend upon observation and induction for the detection of general laws. Very few attempts have been made to introduce the deductive method into the province of biology, and it must be confessed that most examples of this method of inquiry in its application to vital phenomena have only surprised the world with their absurdity. Of late years the inductive method has yielded brilliant results, and it is of great value, inasmuch as it serves to guide men in their inquiries. Doctors are, unfortunately, too often mere observers, whereas a carefully elaborated induction lends immense service by directing the observing faculty and leading to the detection of facts which remained unnoticed when no guiding theory dominated the perceiving power of the observer. Bear well in mind that seeing and perceiving are not identical processes. Often we fail to see things under our very eyes. Frequently we see things which the mind fails to recognise, or if the mind perceives the objective image, it fails to give it any import. Again and again we fail to discriminate accurately between what we observe and what we infer from our observation.

Allow me now to illustrate these forms of intellectual blindness, beginning with blindness of observation. Many of you—the youngest among us—think it is very easy to observe. Quite so; few things are easier. It is as easy as writing a legible letter, examination paper, or prescription, yet how few of us take the trouble to write them clearly or distinctly. To write distinctly requires care and attention, to make an accurate observation we must have our wits about us. It is very marvellous that we only, as a rule, perceive things of which we have previous cognisance. For instance, there is every reason to believe that one man and woman in every ten has three nipples. On one occasion a man came into the out-patient room with a well-marked extra nipple. I set my class, consisting of eighteen students, to explore the man and to make a report. Three students actually touched the nipple, and one, after eyeing it critically, suggested that it was "a very curious pimple," but no one identified it as a supernumerary nipple. I was induced to test the observing faculty of my class in this manner because I had previously practised the same thing on the excellent assistant in the prosector's room at the Zoological Gardens, in the following manner. As supernumerary mammæ and nipples are so frequent in mankind, they ought, theoretically, to be common in quadrumana. At this time about one thousand dead monkeys of divers species had passed under my immediate notice, but I could not remember to have seen a monkey with more than two nipples. On making inquiries of those likely to be acquainted with specimens I could not get any satisfactory information. The assistant was then directed to examine carefully all dead monkeys for this purpose. About a month afterwards, on making my usual visit, a dead monkey was upon the table, and I at once asked the assistant to examine it. He failed to detect anything abnormal. You may imagine his surprise when the large mamma and nipple shown in Fig. 1 was pointed out to him. Since then I have detected the occurrence of supernumerary nipples or mammæ in male and female monkeys, and feel satisfied that many such specimens have passed under my eyes previously, but that I was so blind as not to see them until a special interest in the question attracted my attention to the matter and led to the detection of what I believe to be the only known specimens of accessory mammæ or nipples in quadrumana. These are not selected as isolated instances of gross defects in observation; similar instances occur almost daily, and I think it is capable of explanation.

You must not run away with the notion that because the abnormality in question is so clearly and deliberately marked in the diagrams, it is as easily observed in nature; no one could for a moment examine the drawing and miss the points which it is intended to emphasise; and it is for this reason that the faculty of observation cannot be obtained or cultivated by studying books. Indeed, the great predisposing cause of intellectual blindness is that, as students, we place too much reliance on books. Knowledge of biology obtained merely by studying books, though infinitely better than ignorance, is at best only half knowledge; and it is a source of distress—great distress—to me to see students learning anatomy from a cram-book in a secluded nook of the garden or theatre, at a time when a demonstration is actually being conducted over the part they are reading in an adjoining room.

FIG. 1.



A female monkey with a supernumerary mamma.

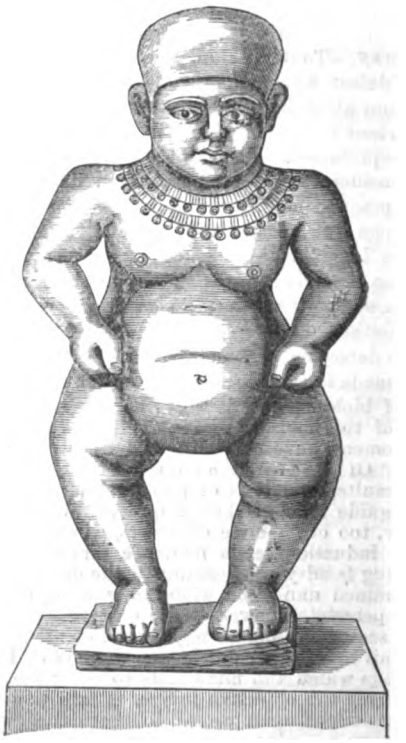
Many of us have known men who read their anatomy book so frequently that they could recite pages from memory with the same facility with which, as children, we prattled through the Ten Commandments and the multiplication tables, yet, when brought face to face with the dissected subject, fail to recognise the parts with which in print they were apparently so familiar. Indeed, I assure you that to study anatomy, surgery, and pathology merely in books, rather than practically, can only be compared to hunting over a rough country on a lean old hack without saddle or bridle. The examples of defective observation which have been put before you are in themselves of little intrinsic importance; but it is clear to my mind that if we constantly overlook things of this nature we also miss things of far greater import in our daily examination of patients, in part from haste, in part from imperfect knowledge; for we may safely assume that the more accurate and extensive our knowledge is, the less likely are we to make errors in our observations, for, as a rule, we only inquire for and note those symptoms which our knowledge of the disease leads us to expect. For instance, a

Digitized by Google

patient complains of pain in the hip, and a careless or hasty inspection of the patient leads to the inference that it is commencing hip-joint disease. A thoroughly trained and cautious surgeon examines the region of the kidney, and succeeds in detecting as the cause of the trouble a renal calculus or a perinephritic abscess. In order to illustrate still more forcibly the need for training and care in observation, we need only turn for a few moments to the subject of sporadic cretinism. You are aware that many Alpine districts are notorious for cretins; these are idiots of stunted stature, with an enlarged thyroid body (goitre). Until recently it was little thought that cretins occurred in England, until the late Dr. Hilton Fagge published an admirable paper in 1871 showing that we had cretins identical with the endemic cretins of Alpine countries. Sporadic cretins have, since the observation of Fagge, been detected in London and many parts of England, and those who have had opportunities of inquiring critically into the matter are almost unanimous in regarding the sporadic form of the disease as identical with endemic cretinism. My own inquiries into the question have convinced me that the two forms agree in their main characters, and, far from being a rare disease, it is not by any means uncommon. In defence of our blindness in failing to detect these cases until Fagge opened our eyes, it may be urged that the affection has recently appeared among us. To this I may at once reply: Museum specimens clearly attest its existence in England certainly one hundred years ago. The identity of sporadic and endemic cretinism works out in another way. H. Müller, Eberth, and others have described, under the name of fœtal rickets, cretinous calves and lambs. Calf-cretins present easily recognisable characters, and a specimen calved in England, which I examined at the "Bell and Mackerel" public-house in the

FIG. 2.

A calf-cretin calved in England.



Mile-end-road, is sketched in Fig. 2. It is twelve inches long, its legs two inches, and its head is short like that of a pug dog.

Dr. Parrot of Paris suggested that the ancient Egyptians were acquainted with cretinism, and even had a cretinous god—PTAH—which was particularly venerated at Memphis. An examination of the models of this god preserved in the Egyptian galleries of the British Museum shows that in some PTAH is represented as a big-bellied, squat divinity, with short limbs, not unlike a cretin; in others he is represented as of noble figure, the type of majesty and lordly bearing. The notion that the dwarf models of PTAH were acquired from cretins is, however, very speculative. Certainly the Egyptians entertained queer notions and adopted strange customs, even preserving their anencephalic babies by mummifying them and preserving them in tombs. (Fig. 3.)

You must not think that whilst endeavouring to point out the motes in the eyes of others I am insensible to the beam in my own eye; far from it. Let me detail to you an error of which I am ashamed. Some three or four years ago the subject of avian tuberculosis occupied my attention; the results were embodied in a rather lengthy paper contributed to the *New York Journal of Comparative Medicine and Surgery*, October, 1886. In that paper a parrot's foot is represented (this sketch is reproduced in Fig. 4), with several irregularly rounded nodules upon it, which in their general characters resembled the nodules so common in the tuberculosis of birds. In 1884, Dr. O. Larcher published some observations on these nodular formations, and insisted that they were gouty deposits. It so happened that in several cases in which I had examined the deposits on the feet of birds and in their viscera, tubercle bacilli were present, and as the nodules on the feet of the parrot resembled those in which I had found tubercle bacilli, they were attributed to tuberculosis. This was a grave error on my part, but fortunately the specimen was carefully examined at the Royal College of Surgeons, and the deposits found to contain needle-shaped crystals resembling those found in gouty deposits in man. We should all endeavour to profit by our mistakes, and certainly this little experience has been to me of great advantage, and the subject is certainly of interest to physicians.

It is well known that pigs suffer from a parasitic affection

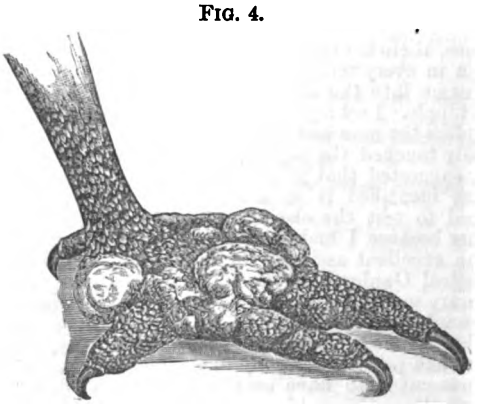


FIG. 3.

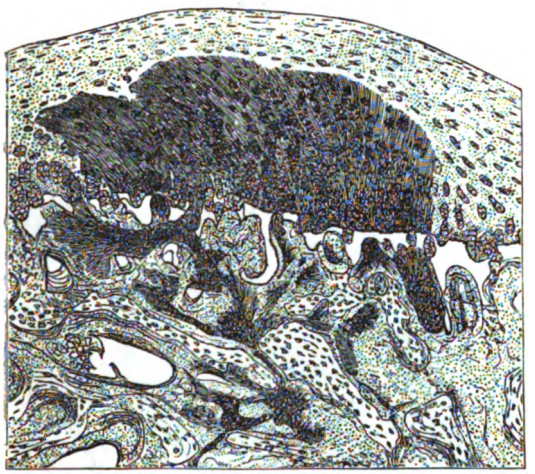
The Egyptian deity PTAH, supposed to be a cretin. (From models in the British Museum.

named trichinosis. The parasites (trichinæ) lodge by thousands in the muscles, and become surrounded or encysted by lime salts. On examining trichinosed pork, the parasites are seen as small white specks dotting the lean parts. In 1866 Virchow had submitted to him some ham supposed to be trichinosed because it was spotted with

FIG. 4.

A parrot's foot with gouty nodules.

small white concretions. These deposits were found on chemical examination not to be trichinæ, but collections of crystals of guanin. Since that date few observations have been made on the subject, although it is one of great interest. Guanin is a nitrogenous crystalline body resulting from the metamorphosis of animal tissue; it was first dis-



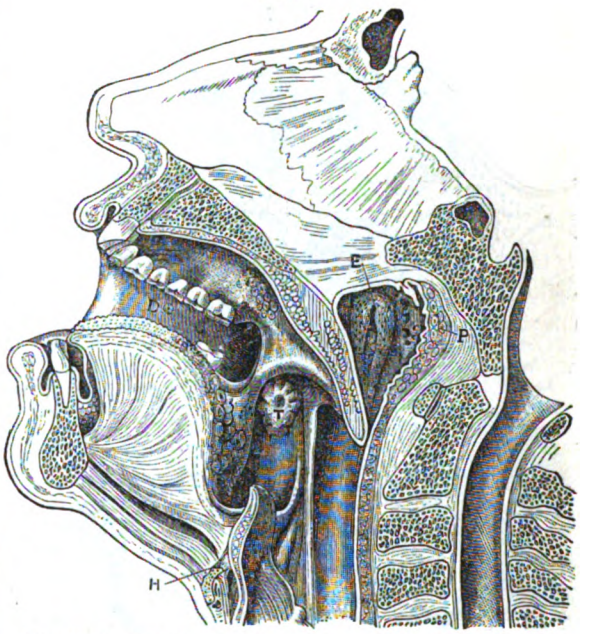
Digitized by Google

covered by Unger in Peruvian guano, and its presence in this substance may be accounted for as the scales of fish contain a quantity of guano lime. The guanin deposits in the hog occur in the ligamentous tissues, in the articular cartilages, and in the fibrous septa of muscles in the form of acicular crystals collected together in irregular heaps, and form arborescent figures. (Fig. 5.)

This subject has been admirably investigated by Mendelson, and an excellent account of this guanin gout is furnished by him in the *International Journal of Medical Sciences*, vol. xcv., p. 109. A glance at the drawing of the relation of the crystal to the articular cartilage of the knee-joint will show at once the close resemblance to the deposits of urate of soda in human gout, and serves to show how justifiable it is to apply the name guanin gout to this condition.

Not long ago I ventured to state in a paper that, as far as my observations on disease extended, gout seemed to be one of the few affections peculiar to the human species. Sir Alfred Garrod, known all the world over for the attention he has given to gout, states that certain birds and reptiles, when in captivity, have sometimes concretions around their joints which closely resemble gouty deposits in man. Aldrovandi has noticed them in the falcon, and

FIG. 5.



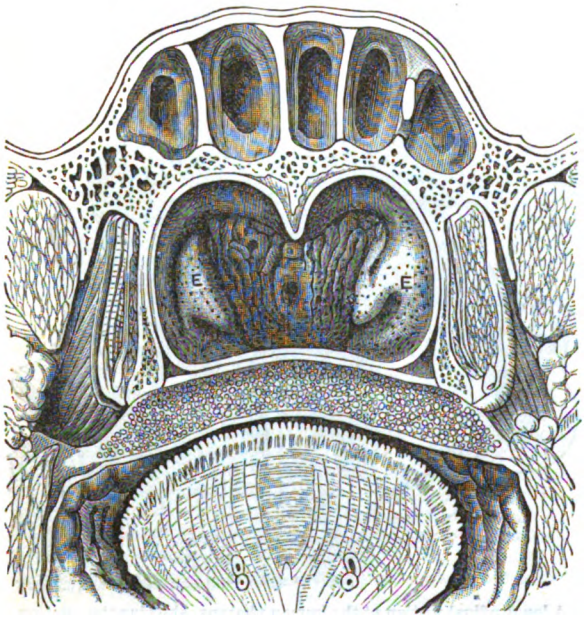
Section of the articular cartilage of the knee-joint of a hog, with deposits of guanin. (After Mendelson.)

M. Berlin of Utrecht has several times observed in the parakeet the presence of masses upon the metatarsal joints and toes composed of a white plastery substance, exhibiting both microscopically and chemically the characters of urate of soda. Garrod then says: "My own very limited examination of tumours upon the legs of birds has given me as yet only negative results." As a matter of fact, these plaster-like masses in the subcutaneous tissues of the legs and toes of birds are very common, and resemble in every way the chalky collections in human gout. Parrots also present deposits in their muscles which in every way resemble the concretions seen in the lean of ham obtained from pigs, the victims of guanin gout, and until someone sufficiently cunning in physiological chemistry takes an interest in the question it will be impossible for us to decide whether the gouty concretions on the legs of parrots are due to urate of soda or guanin. But another circumstance comes in; urate of soda and uric acid are very abundant in birds, but guanin is said not to occur in the urine of the lower mammals or man. Whence comes the guanin in the hog?

It also becomes a matter for inquiry, if, in all cases of human gout, the deposit is constantly urate of soda, may it not occasionally be guanin? This is an interesting question, but on the present occasion the subject is introduced for the purpose of showing how difficult it is in some cases to make accurate observation, and how very easily we may be deceived even in matters of which we are conceited enough to think that we possess adequate knowledge. The value of accurate observation is inestimable; it is impossible to predict the results to which a good observation may lead, and the aphorism "that the unexpected frequently happens in science" is as true in the art of medicine and surgery as in the science of chemistry. This is well illustrated by the advance made in recent years in the treatment of a peculiar affection of the naso-pharynx. In 1868 the eminent anatomist of Tübingen, Luschka, drew attention, in an elaborate and painstaking monograph, to the existence on the posterior wall of the pharynx, at the angle where it joins the roof, of a body which he named the pharyngeal tonsil. Its relation to the surrounding parts is represented in the accompanying diagram. (Fig. 6.) The history of this tonsil is replete with interest, but on the present occasion it would be very inappropriate to enter upon it at any length; indeed, all I need say is, that in general structure it is analogous to the part ordinarily known as the tonsil, and, under the microscope, sections from the guttural and pharyngeal tonsil cannot be distinguished from each other. Surgeons have long known that the tonsils are liable to enlarge in young people, inducing a habit of breathing with the mouth half open, snoring in sleep, and, what is very disagreeable, deafness. In very many cases the removal of the tonsils has sufficed to remedy or relieve these defects, but in a very large number of cases, even after the removal of the tonsils, the deafness still remained. In October, 1869, exactly twenty years ago, and that is one of

FIG. 6.

A longitudinal section of the human pharynx, showing the relation of the pharyngeal tonsil. (Modified from Luschka.)



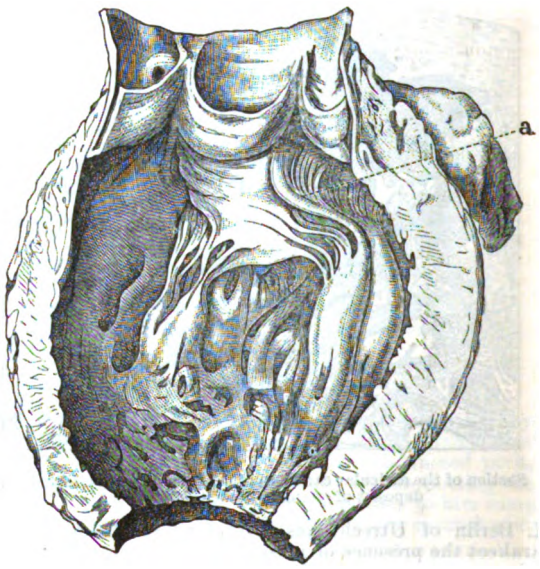
my excuses for mentioning the matter here to day, Meyer of Copenhagen published in the Medico-Chirurgical Society's Transactions an admirable paper, and showed most conclusively that these troubles are often due to what he called "adenoid vegetations of the naso-pharynx," or what may in simpler terms be described as enlargement of the pharyngeal tonsil. It will be seen at a glance, on referring to the transverse section of the head in Fig. 7, that when this tonsil enlarges it must laterally compress the orifices of the Eustachian tubes and induce deafness; anteriorly it projects into the nasal passages, obstructs respiration through the nose, and induces snoring, oral breathing, and imparts a disagreeable sound to the voice. Meyer's claims to our admiration extend beyond this, for he not only discovered the cause of the trouble, but clearly indicated the way to remove it; and though the operation he proposed has been modified by surgeons, the principles of treatment inaugurated by Meyer remain. The results which have followed the general adoption of the operation are best set forth in the words of Sir Morell Mackenzie in his presidential address to the first meeting of the British Laryngological Society, November, 1888. They were to this effect: "The cure of adenoid vegetations has resulted in the prevention of deafness to such an extent that there are probably at least 100,000 persons now hearing well

Digitized by Google

who, had it not been for Dr. Meyer's valuable discovery twenty years ago, would now have been hopelessly deaf." The numbers quoted by Sir Morell may sound high, but my own inquiries into this matter leave no doubt in my mind that he has, if anything, understated the good results.

Correct observation is a matter of the greatest necessity, for on what we observe we have to make an interpretation and frame a line of action; consequently, if the observations are faulty, the interpretations we place upon them are as valueless as if, in taking a ship's position at sea, we mistake the star in the tail of ursa major for that in ursa minor. In our daily occupation as physicians and surgeons it is not only necessary for us to make, as far as possible, accurate observations, but also to correctly interpret them, because upon our interpretation the life of the patient not infrequently hangs, and this alone should induce us to make ourselves masters in the art of observation and cunning in interpretation. This is, of course, very difficult, and the saying "Jupiter sometimes nods" merely means that the greatest amongst us occasionally overlooks things. Even men who have been regarded as admirable observers have committed grave errors, both in observation and interpretation. The following case, which was under the care of an excellent physician, illustrates this.

FIG. 7



Transverse section of the head, showing the pharyngeal tonsil. (After Luschka.)

A patient from a poor and insanitary neighbourhood was admitted into a large London hospital suffering from symptoms of fever. In addition to a high temperature, the skin was covered with small red spots, which did not disappear on pressure. A peculiar subcutaneous mottling was present, and on turning down the bedclothes a peculiar mouse-like odour became distinctly perceptible. The tiny red spots were regarded as flea-bites, and there were unmistakable evidences of these athletic insects. The mottling of the skin and the mouse-like odour were attributed to the infrequent use of soap and warm water; the temperature was unaccounted for, and the nature of the illness remained for some days in doubt. It soon became clear that the disease was typhus fever; the red spots, subcutaneous mottling, mouse-like odour, and temperature were all characteristic of the affection. Unfortunately the correct diagnosis was made a little too late, as the nurse had carried the affection to a patient on the opposite side of the hospital. This case is by no means an isolated instance of the need for care in observing and interpreting symptoms. The question is an important one for the public at large, as well as for the patient and friends; and I am well within the mark in stating that you will not be many weeks in practice before being called upon to decide some case quite as critical as the one just mentioned.

Let me urge you not to limit your attention to man. Everything that lives has an interest for us. Bacon has said, "No natural phenomenon can be studied in itself alone, but to be understood must be considered as it stands connected with all nature." And if this be true in small things, how much the more must it apply to what John Hunter called the most complicated part of the whole animal creation—man.

It has often struck me what a lot of energy men would save if in their earlier years they would study a few animals besides men, women, and children, and how very simple many apparently obscure phenomena would become. I will illustrate this by one example. In February, 1858, a human heart was exhibited at the Pathological Society, London, and described in the Transactions under the following title: "Heart showing a large patch of striated muscular fibre situated in the substance of the anterior segment of the mitral valve." The description of the specimen leaves no doubt that one of the flaps of the mitral valve in this heart (which was removed from a man twenty-five years of age) contained a piece of muscular tissue the size of a fourpenny piece. (Fig. 8.) The exhibitor then indulged in rather more than six pages

FIG. 8.

The anterior flap of the mitral valve of a human heart, containing a patch of striated muscle fibre.

of close reasoning, and concluded "that it is an instance of a congenital accumulation (amounting to malformation) of the transversely striped muscle fibre, found naturally, but very sparingly, to exist in the part." As a matter of fact, the explanation is simple enough; in the embryo the valves are muscular projections from the cardiac walls which gradually become in man and nearly all mammals tendinous. In birds and some mammals (echidna) the tricuspid valves remain as muscular folds throughout life. The wonder is, not that such a specimen came to hand, but that many more such specimens have not been noticed. In every department of our profession there is the greatest need for caution in interpreting observations; in experimental physiology and pathology, where results are stated with almost mathematical precision, the greatest caution is required. This is so important that it is needful to illustrate it. It is now well known that the sphincter muscle of the mouth in mammals, the orbicularis oris, has distributed to it two distinct nerves, the seventh, or facial nerve, supplying it with motor power, and large branches from the fifth, conferring upon the muscle and its cutaneous covering sensation. The relation of these nerves to each other in the neighbourhood of the mouth of an ass are admirably shown in this bold drawing made by Sir Charles Bell, whose name in this school must always be mentioned in terms of the highest respect and admiration. The fact that the fifth nerve confers sensation and

Digitized by Google

the facial motion is to us nowadays so simple that we can scarcely appreciate the difficulty which seems to have existed in the mind of Bell and his contemporaries as to the part played by these nerves individually. Charles Bell had, with others, come to the conclusion that the fifth nerve, in so far as the lips and face were concerned, must be regarded as a sensory nerve. He then endeavoured to substantiate the opinion by experiment, and, as a consequence, fell for a time into grave error. He found that if an ass be tied and thrown, and the superior maxillary branches of the fifth nerve cut on each side, and the animal be let loose, it will not pick up the corn; the power of elevating and projecting the lip, as in gathering food, appears lost. The animal will press its muzzle against the ground and at length lick the oats from the ground with its tongue. From this, Bell came to the conclusion that the power of the orbicularis was lost in consequence of the division of the branches of the fifth nerve distributed to it. In this experiment the observations were correctly made, but they were incorrectly interpreted, and Bell found himself unable to reconcile his observations on man with his experiments on mammals.

These contradictory results were at last reconciled by other experimenters; the ass did not feed after the second division of the fifth nerve had been cut on each side, because the lip, being deprived of sensation, could not feel the oats or grass. Thus we must coincide with the opinion expressed by Bell that in this matter the truth had been nearly obscured by experiments. Conclusions drawn from experiments upon mammals and applied to man must be received with the greatest possible caution. During the last five or six years a large number of experiments have been conducted with the view of determining the best method of suture for mending damaged intestines. In most instances the experimenters have selected dogs. Of all mammals, dogs (and carnivora generally) have the thickest intestines, and they may be handled, clamped, and stitched almost as freely as if they were coils of indiarubber tubing. Human small intestine is of very different texture, especially when distended and inflamed; thin, delicate, easily torn, and liable to inflame with little provocation. With such conditions, is it at all likely the results obtained from experiments on the small intestines of a dog could be possibly expected when attempted on man?

Because I venture to criticise the results of such experiments you must not regard me as hostile to experimental physiology and pathology; on the contrary, I am of opinion that it is of the greatest utility, for, as John Herschel pointed out in regard to natural philosophy, those departments in which experimental inquiry cannot, or from causes beyond our control, has not been carried out, the progress of knowledge has been slow, uncertain, and irregular; while in such as admit of experiment, and in which mankind have agreed to its adoption, it has been rapid, sure, and steady. These remarks apply as forcibly to biology in general as to natural philosophy.

In conclusion, gentlemen, let me urge you to use fully all those powers which God has given you, and struggle hard not to become intellectually blind to any serious extent. Training in the art of observation will be afforded you in the dissecting-room, and practice in observing and interpreting will be furnished in the out-patient room and wards of the hospital, under the guidance of the physicians and surgeons. To those of you who possess in a high degree the power of interpretation, great professional power may lie within your reach. Those of you who are furnished with this power in a moderate degree may yet attain great things by close application; but all must bear in mind that we have no special sense on which we can rely; vision, hearing, touch, and taste cannot be trusted unaided, and may deceive us when we think ourselves most awake and on the alert, cozening and causing us no small amount of mortification. If you read the lives of the greatest men, from Moses, who was a leader, warrior, lawyer, sanitarian, and physician, to Darwin, you will find that those excelled most who were not merely critical and keen observers, but able to place correct interpretations upon what they observed. I do not mean to lead you to believe that the possession of the highest intellectual vision will in this profession induce a Pharaoh to confer upon you a viceroyalty; it may, however, gain for you the friendship of a monarch, and, what is more valuable, the esteem and respect of mankind; whilst the results of your interpretations may confer incalculable good upon your fellow men, and reward you with mental satisfaction inexpressible.

A CASE OF

EXCISION OF BOTH HIP-JOINTS FOR ACUTE DISEASE; RECOVERY.

BY WILLIAM HENRY BATTLE, F.R.C.S.,
ASSISTANT SURGEON TO THE ROYAL FREE HOSPITAL AND TO THE EAST LONDON HOSPITAL FOR CHILDREN, SHADWELL; FORMERLY RESIDENT ASSISTANT SURGEON AND SURGICAL REGISTRAR, ST. THOMAS'S HOSPITAL

CASES of disease of both hip-joints are fortunately of rare occurrence, and this one presents several unusual features. Amongst these are, the onset of acute disease on each side within a short period of time, the extent of this, the bad condition of the patient when admitted, the *necessity* for excising *both* joints, and the success which has followed the methods of treatment employed during the long period that he was in the hospital. I have waited for some months before bringing the case forward, in order to make certain as far as possible that the recovery is a complete one; now examination shows not only that the hips are firmly healed, but also that the general condition of the boy is good, whilst his power of locomotion exceeds my expectation.

R. L——, aged fourteen, was admitted into the Leopold ward of St. Thomas's Hospital on May 24th, 1887, and left for a convalescent home on Oct. 2nd, 1888. He was admitted under the care of Sir W. Mac Cormac, who kindly gave me permission to treat the case. The patient was said to have always been a delicate boy, but had suffered from no serious illness. There was no history of injury. Eight weeks before admission he went to bed feeling quite well and without any pain anywhere, but on the following morning he complained of pain over the left hip. This pain was very severe and increased in severity, so that he was obliged to take to his bed, where he has since been kept suffering from severe pain in his hips, for pain and swelling came on in the right hip soon after the left hip was affected. The father, a blind beggar, has not been heard of lately. Mother and one sister died of consumption. One sister had something the matter with her hip when a child and walks lamely, one leg being shorter than the other.

On admission the boy was in a most serious condition, and appeared to be suffering acutely from disease of both hip-joints. He refused to straighten either leg, and screamed violently when moved or touched. He lay doubled up, partly on his left side, and partly on his face and chest. There were bedsores over all the bony prominences—shoulders, elbows, heels, and even over the ribs—the bone being exposed over the left scapular spine and prominence of the sacrum. The boy was so thin that the skin appeared to be drawn over the bones. He was sweating profusely, had constant diarrhœa of watery, slimy, very offensive motions, obstinate vomiting, and a most offensive mousy smell. The temperature was high (104·2°). With considerable difficulty it was possible to examine the hips more closely. There were much swelling and œdema about the right, chiefly marked over the front of the joint, but on this side fluctuation was not well marked, and disease did not appear to have invaded the gluteal region. The pain on attempted movement was severe—in fact it was not possible to examine fully without an anæsthetic. The thigh was flexed, but not so much so as on the left side, the right knee crossing the upper part of the left leg, the thigh being slightly abducted. The left hip presented a large globular fluctuating swelling, which extended round the great trochanter and upwards and backwards into the buttock. The top of the great trochanter was three inches above Nélaton's line, and the thigh inverted, adducted, and shortened to a corresponding extent. It was not considered advisable to do anything then beyond procuring relief of pain, the administration of suitable food with the intent to improve his general condition, and the application of antiseptic ointments to the bedsores, with general nursing. He was placed on a water bed. During the 25th and 26th his general condition improved somewhat, but he appeared to suffer very much, screaming continuously, and disturbing the whole ward. The sweating and diarrhœa continued. The temperature on the evening of admission was 104°, at midnight on the same day 101°, and at 9 A.M. next morning 99·2°, rising to 101° at 8 P.M. On the 26th it reached 102° at 8 P.M. The urine was found to have a sp. gr. of 1020

Digitized by Google

and to contain one-fourth of albumen. The other organs were apparently healthy.

On the 27th, in the afternoon, it was thought best, considering the boy's temperature, excessive pain, with the presence of so much pus about the left hip, to attempt to relieve him. Ether having been administered, an incision was made, about four inches in length, in a direction from below upwards towards the posterior superior spine, with the limb at an angle of 45° to the trunk, commencing about an inch below the top of the great trochanter and crossing its middle. This gave exit to several ounces of thick pus, and the finger introduced through it felt the head of the bone lying on the dorsum ilii. It was bared, bathed in the pus, and quite devoid of cartilage. The ilium was also bared for some distance around; the acetabulum was bared in a similar manner, but nowhere was there any granulation growth, such as one usually finds in tubercular disease. The head of the bone could not be brought to the acetabulum, so the neck was divided with a saw, and the head removed. After this the sawn surface of the neck could not be made to descend lower than the upper margin of the acetabulum. The cavity was washed out, and then sponged with a solution of chloride of zinc (forty grains to the ounce), again syringed with carbolic solution (1 in 40), a few silk sutures inserted, and a large drainage-tube put in. The wound was dressed with iodoform and salicylic wool. A long outside splint with extension was applied, and the bedsores dressed. The boy's condition did not allow of prolonged anæsthesia. On coming round from the ether he appeared relieved. At night the temperature was 100·6°. No evidence was obtained as to the original point of origin of the disease.

28th.—Passed a comparatively easy night. Says he is much better; is much less noisy, and seems greatly relieved. The diarrhœa continues. Does not complain of the right hip, which is now red and more swollen.

30th.—Placed in a double Thomas's splint (Croft's modification). Between this date and June 7th the temperature for two or three days was quite normal, but usually varied from 100° to 101° at night. He had much improved in general condition, but complained of a great deal of pain in the right hip, the swelling of which was increasing. On this date it was decided to incise the abscess from the front, adopting Parker's incision, with the intent to proceed further should the condition of the joint indicate it. The incision made was about three inches and a half in length, and gave exit to a large quantity of pus. On passing the finger into the joint a loose piece of bone was felt, and extracted, after flexion of the thigh, by means of necrosis forceps. This proved to be the separated, disc-like epiphysis of the head of the femur. As on the left side, there was little granulation growth, and the neck of the femur for a short distance, as well as the acetabulum, was bared and rough. As it appeared that this was a secondary process I did not remove anything further, but, having made a counter-opening behind, the entire wound was washed with chloride of zinc solution (40 gr. to the ounce) and carbolic acid solution (1 in 40), sutures inserted in front, and dressed with iodoform. The wound on the left side was also dressed; it was looking healthy and healing rapidly. He bore the operation very well.

June 14th.—Has been complaining of some pain in the right hip since the operation, but to-day says that he has no pain. Both hips are looking healthy, and there is very little discharge. He complains more of the bedsore over the sacrum; the other sores are healing. He is sleeping well, takes an interest in the ward, is cheerful, and allows movement without screaming. His appetite is improving. There is less sweating, and his body does not smell so offensively, but he is still so dirty in his habits that it is difficult to keep the wounds aseptic. The stitches and tubes were all removed from the left hip. The pressure of the splint at the knee had caused a small sore; the skin cannot bear the slightest pressure; sores form, even with firm bandaging. A mixture containing perchloride of iron was given.

24th.—Has much improved in health. His pulse is stronger and less rapid. The wounds are healthy in appearance, and there is less discharge. He is more cheerful, but decidedly deaf. A Bryant's double hip splint was applied.

26th.—There was a return of the diarrhœa, which was arrested by the addition of ten minims of tincture of opium to the medicine.

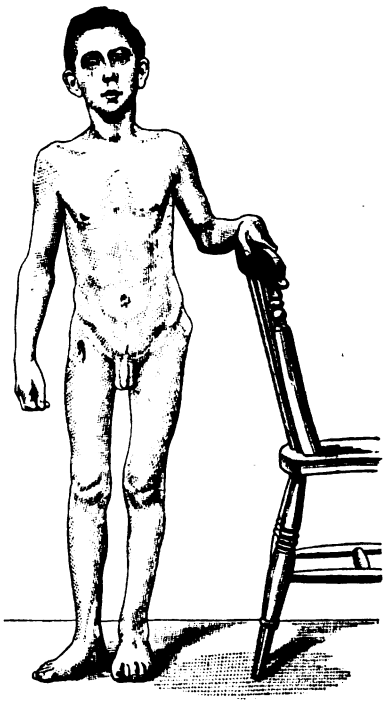
July 4th.—The left hip is now quite healed, and there is no pain on pressure. All the bedsores excepting the one over the sacrum are healed. He sleeps and takes food well. Is rapidly improving in every respect.

13th.—Quinine and acid mixture substituted for the iron mixture.

30th.—The improvement continues, though it is slow.

Aug. 12th.—Towards the end of June an abscess was opened in the right adductor region, from which there has been much discharge. The tube was removed this morning.

20th.—Both hips are healed. The boy is putting on flesh. The skin has lost its harshness, and is a better colour. The limbs are in good position. The bedsore over the sacrum still requires attention, though it is much improved.



Sept. 2nd.—The tube which was placed in the counter-opening behind the right hip was removed.

14th.—All dressings have now been discontinued to the hips. Massage to be employed gently with cod-liver oil for a quarter of an hour twice daily to the whole body.

30th.—Quinine and iron mixture given. On removal of the splint, the legs were found to be quite parallel and in good position; they were, however, much wasted.

Oct. 22nd.—The massage with cod-liver oil appears to have been most beneficial. It is now employed for half an hour three times a day.

Nov. 13th.—The bedsore over the sacrum is nearly healed.

Pulse still rapid (120). A teaspoonful of Easton's syrup given three times a day.

Feb. 27th, 1888.—From this date until April 1st he suffered from an attack of cutaneous erysipelas, which, commencing in the right thigh, spread up the back to the neck, across the trunk, and down to the toes. The attack was ushered in by vomiting, headache, and shivering, which lasted for two days before the appearance of the eruption. It was also preceded by enlargement of the femoral glands, which had been observed for a period of five days. This enlargement of the glands continued throughout the attack. A double Thomas's splint was substituted for the Bryant in January, as it was lighter and the patient easier to handle in it.

May 1st.—All the sores are healed. He now gets up, can stand by himself, but is not able to walk without help. He is much stouter.

12th.—The patient having been deaf for some weeks was Politzerised a few days ago, and it has been repeated. He now lies in bed with the bedclothes drawn up; looks dull and stupid when roused; complains of headache and dizziness; has vomited, and appears pale and ill. The temperature has continued normal for a long time. These symptoms gradually subsided, no further treatment of the deafness being employed.

Digitized by Google

16th.—Mr. Lawford examined his eyes, which had exhibited a tendency to nystagmus since he was admitted. Refraction myopic, astigmatism in each eye; no change in the fundus, excepting great tortuosity of arteries and veins.

June 16th.—About a fortnight ago he was fitted with double apparatus for the hips, there being a pelvic band with iron supports extending down the outer side of each limb, with movable joints at the knees and ankles. The left leg is rather more than half an inch shorter than the right. This apparatus enables him to get along slowly without help.

He was kept in the hospital until Oct. 2nd (a period of 400 days), on which date he was sent to Margate.

With the exception of a few days at the beginning of July, 1887, when the temperature rose two or three degrees at night, it was normal after June 18th of that year, and rarely reached 99·6° during the whole of the after-treatment, excepting during the attack of erysipelas.

Remarks.—The short account of this boy's state on admission shows what excellent attention and care he must have received from the house surgeons, dressers, and nursing staff before he could be brought into what might be called a fair state of health. I regret that I cannot mention them individually. Reference has already been made to the rarity of double hip disease,[1] and the majority of cases recorded have been examples of tubercular caries arising in a second joint whilst the patient was already under care for disease of the other side. The disease has usually been of chronic character. In this case the disease was of an acute nature on each side, and rapidly ran on to complete disorganisation of the joint. The necessity for excision was evident, the choice of time for the operations less so. The patient came to see me on Oct. 2nd of this year, and surprised me by the rapidity with which he could walk without the aid of the apparatus, which he had continued to wear since it was supplied, or other assistance. The woodcut is from a photograph kindly taken by Mr. W. Edmunds more than fifteen months ago. The patient is now taller, and the muscular development, especially below the knees, markedly increased. The left limb is an inch shorter than the right, but this is hardly apparent. In the majority of the cases of hip disease affecting both joints it has only been necessary to employ prolonged rest, with extension and appropriate splints, as when the disease affects one joint, the only operative treatment required being incision of abscesses. In one case, however, which was placed under my care, I excised the left hip-joint, and Mr. H. B. Robinson of St. Thomas's Hospital afterwards found it necessary to operate on the right side; the patient is still under observation. I can only find records of three other cases of excision of both hips. Mr. Croft[2] recorded a case in 1879 of excision of both hip-joints for femoral necrosis, in a girl of four years of age. The duration of the disease was eleven months, and an interval of three weeks elapsed between the operations. The femora were sawn at the level of the base of the great trochanter. The patient made a rapid recovery, and was last seen in October, 1883. She was not able to walk well then. In another case this double operation was performed by Dr. Ashhurst.[3] The patient was a boy about twelve years of age. The right hip had been diseased for eight months, and the left for a longer period. The operations were performed at an interval of seven months and a half. On the right side the head of the femur was carious, and on the left there was a sequestrum in the acetabulum. He recovered, but could not walk without support two years later. Dr. Byrd[4] of Illinois read notes of the case of a girl aged ten years, for whom he had excised both hip-joints. The upper ends of the femora, which were extensively diseased, were removed just above the great trochanter. At the time the case was brought forward, the patient was able to go up and down stairs without crutches, and over smooth ground. In these cases passive movement was commenced not long after the operation, but in the case recorded above the condition of the boy was such as to make any disturbance of the parts undesirable until after too long a period of time had elapsed to make movement of any value.

COCAINE IN DIABETES.

By THOMAS OLIVER, M.A., M.D., M.R.C.P.,
PROFESSOR OF PHYSIOLOGY IN THE UNIVERSITY OF DURHAM AND PHYSICIAN TO THE ROYAL INFIRMARY, NEWCASTLE-UPON-TYNE.

IN the course of diabetes it is no uncommon thing to find that glycosuria disappears on the development of an illness attended by febrile exacerbations. Towards the termination of diabetes, when phthisis is fully developed, we frequently notice that sugar disappears from the urine as the temperature becomes high. A high temperature, or perhaps more correctly speaking the condition which causes the temperature to become high, is thus seen to be followed by a disturbance of the glycogenic function of the liver. Is it possible that diabetes may be thus cured? Here is a case which lends weight to such a probability. A gentleman in this neighbourhood had been several months under treatment for diabetes. Contrary to medical advice, he went to the races one cold day, where he got chilled. He had shortly afterwards a rigor, which was followed by an atypical pneumonia attended by a considerable rise of temperature. The urine was now found to be quite free from sugar, and it remained free from sugar for more than a year, during which time the patient had quite regained, and felt himself in, his usual good health. From observation of these facts, it would appear as if the employment of medicines of the pyrogenic class might be followed by good results in the treatment of diabetes. Hence my reason for trying cocaine in the following case.

C. H——, aged forty-three, a cabinet-maker, was admitted into the Newcastle Infirmary on March 15th, suffering from diabetes of five months' duration. His mother died in an asylum at the age of fifty; the rest of the family history is on the whole good. Five months previously he had noticed that he was passing too much urine, and that his thirst and appetite were excessive. Prior to this he had suffered much from anxiety and worry in business. His skin is dry and shows here and there patches of psoriasis. Beyond puerile respiration at the apices nothing abnormal is detected in the lungs. His heart is healthy. In the abdomen nothing abnormal is noticed. He has, however, the gait of an ataxic. In walking he sways from side to side, is very unsteady, says he feels as if the floor were going up and down, feels giddy, and complains of numbness in the arms and hands. He does not fall, however, when his eyes are closed. Knee-jerks are present, but the response is slow and the amplitude large. Pupils are normal. He is the subject of delusions. When he awakes during the night he sees various objects with a peculiar colour, particularly men wearing black hats and yellow tassels. Temperature normal. Is passing thirteen to sixteen pints of urine daily, acid, specific gravity 1034; no albumen. The amount of sugar varies from 6000 to 7000 grains daily. He complains of a most obstinate constipation. His bowels are not relieved for six or seven days at a time, even though strong purgatives are employed aided by enemata. He is sleepy. At first I treated him by codeia, and, gradually increasing the dose, it was noticed that the urine fell to eight pints daily and the sugar to 4000 grains. Beyond this diminution in the amounts of urine and sugar eliminated daily, it was noticed that there was no improvement generally; the patient's symptoms remained the same. So I determined to try cocaine. This I gave in quarter-grain doses three times a day. Until now one of the most difficult symptoms to treat in his case was the obstinate constipation, but he had only taken the cocaine a few days when the constipation entirely ceased, and his bowels, which had hitherto refused to act to the strongest purgatives, now began to be moved once or twice daily. His nocturnal delusions also entirely disappeared. On ophthalmoscopic examination, Mr. Williamson, my colleague, reported the existence of a patch of old-standing choroiditis at the inner side of the disc of the left eye, and that the lens and disc in both eyes were normal. His temperature at this period ranged from 97° to 98°. When weighed on April 29th it was found that 6 lb. in weight which he had lost had been regained, and that his bowels continued to act well. In May the patient seemed to be progressing very satisfactorily. Urine varied from six to eight pints daily, and the amount of sugar from 1100 to 3000 grains.

Digitized by Google

His delusions had not returned, he was sleeping and eating well, he had lost his vertigo and the swaying movement he felt when walking; also a painful sense of muscular fatigue of which he had previously complained. Instead of constipation the bowels were now moved sometimes twice and thrice daily. At this stage of his illness—that is, about ten days after this last record—the patient was passing from four to five pints of urine, and the daily average elimination of sugar was 1120 grains. The specific gravity of the urine was a little over 1020. Thinking that the cocaine was acting too much upon the bowels, I stopped it. No sooner was the cocaine stopped than almost immediately the urine rose to seven and nine pints daily, and the average amount of sugar to 3900 grains. Very unfortunately, at this stage, when all seemed to have been going well with him, he injudiciously exposed himself in the garden and caught cold. He now began to cough; friction râles were detected at the base of the right lung in front, and also at the back, where in addition a few crepitant râles could be heard. Treatment by cocaine was not resumed, as the chest symptoms attracted most of our attention. Feet and hands became œdematous, and the amount of urine fell to two pints daily. Later on albumen was detected in the urine, but it was only present for a few days. Râles were now more generally heard over the chest, muco-crepitant at the left apex, and friction and crepitant râles over the whole lung. His course was now downward. His temperature ranged from 98° to 101°. Under the administration of small doses of digitalis the dropsy of the feet, legs, hands, and scrotum disappeared, although the abdomen was still found to contain a considerable quantity of fluid. He ultimately died from syncope.

At the post-mortem fluid was found in the pericardium and the abdomen. The substance of the heart was œdematous. The wall of the left ventricle was thickened. The valves were all healthy and competent. There was a cavity at the apex of the left lung. Smaller cavities and tubercular nodules were found scattered all through the lungs, which were œdematous. The liver weighed 38 oz. Numerous white specks were noticed on its surface the size of a pin's head; they were hard, and evidently were miliary tubercles. The kidneys were pale and contained similar small bodies. The spleen appeared healthy; the mesenteric glands were cheesy. The dura mater was healthy; there was subarachnoid effusion of a milky white character. On section, the brain was found to be firm; it looked pale, but otherwise healthy. Each lateral ventricle contained one or two teaspoonfuls of serum. The vessels at the base in the fissure of Sylvius were healthy. Cerebellum healthy.

The points of interest in this case as the result of the administration of cocaine are—the total disappearance of a most obstinate constipation which refused to yield to the strongest purgatives; disappearance of a gait, not unlike that of ataxia; of delusions, and a sense of muscular fatigue; the return of a feeling of improved health and strength, with a gain in weight; a marked diminution in the amount of urine excreted; a very decided reduction in its specific gravity and a very noticeable fall in the daily elimination of sugar. Cocaine failed, however, to raise the temperature.

Newcastle-on-Tyne.

SOME NOTES ON THE VALUE OF HYOSCINE AS A SEDATIVE.

By WALTER S. COLMAN, M.B., M.R.C.P.,
REGISTRAR AND PATHOLOGIST TO THE NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC; AND
JAMES TAYLOR, M.A., M.B.,
HOUSE PHYSICIAN TO THE HOSPITAL.

DURING the last year we have employed hyoscine frequently in an emergency in a number of cases, any of which might have occurred in general practice. By the kind permission of the physicians under whose care the patients were placed we are enabled to bring the results forward in the present paper. The preparation used was in all cases a 1 in 500 solution of the hydrobromate of hyoscine in distilled water. This strength is a convenient one, five minims being equivalent to a dose of $\frac{1}{100}$ gr. of the salt. (Care should be taken to obtain the hydrobromate of hyoscine from a reliable chemist. It is perhaps superfluous to say that it must not be confounded with hyoscamine).

I.—CASES OF MENTAL EXCITEMENT.

Case 1.—William C——, aged thirty-eight, admitted under the care of Dr. Hughlings Jackson, suffering from general paralysis without mental symptoms, but with all the physical indications typically present. He suddenly had a series of epileptiform convulsions, leaving him permanently aphasic, and partially hemiplegic, and he also became very noisy (and, as far as the paralysis would allow, violent), disturbing the ward by his inarticulate cries. The injection of $\frac{1}{100}$ gr. of hyoscine at once quieted him at first. During the next few weeks he had a frequent recurrence of the noisy attacks, and the dose had to be increased, until at one time he required $\frac{1}{75}$ gr. every six hours. No bad effects were at any time observed due to the hyoscine.

Case 2.—Bridget H——, aged twenty, admitted under the care of Dr. Bastian, suffering from a tumour of the cerebellum. One evening she suddenly became maniacal and suicidal, with hallucinations of sight and hearing. On this occasion the injection of $\frac{1}{100}$ gr. of hyoscine produced little if any effect on her mental condition, but some weeks later, when she had two similar attacks of excitement, the injection of $\frac{1}{75}$ gr. of hyoscine had the effect of completely allaying the excitement and producing sleep for several hours.

Case 3.—George H——, suffering from well-marked general paralysis, the mental symptoms, however, having made their appearance only a few days previously. His wife's account was that he had had no sleep for five days, had become irritable, and had threatened her with violence, and had been squandering his money, ordering numerous suits of clothes of his tailor, &c. When seen he was excited, and had delusions. He complained bitterly of his inability to sleep. An injection of $\frac{1}{75}$ gr. of hyoscine was then given, and in five minutes he was sleeping soundly. He slept quietly for six hours till the afternoon, and subsequently had a good night. The mental symptoms temporarily disappeared, and his wife was able to take him home to the north of England next day without any trouble.

Case 4.—Emily C——, aged twenty-one, admitted under the care of Dr. Ramskill, suffering from epilepsy. A few weeks after admission, after a succession of rather severe fits, she became obstinate and refused her food. The next day she rather suddenly became violent and tried to strike the nurses and doctors. An injection of $\frac{1}{75}$ gr. produced sleep in about a quarter of an hour. During the two days which elapsed before her removal to an asylum could be arranged for, she had six similar injections, with an equally satisfactory result.

Case 5.—Ellen C——, aged twenty-seven, admitted under the care of Dr. Hughlings Jackson, suffering from epilepsy. Coincidently with the appearance of the catamenia (which had been suppressed for some months previously), she became sleepless and noisy, with hallucinations of sight and hearing. When she was in this condition, $\frac{1}{100}$ gr. of hyoscine would quiet her within five minutes, usually producing sound sleep, and on awaking she was for some hours free from the hallucinations and much more manageable. She had about twenty such injections, which had no untoward effect on her mental condition, which steadily improved.

Case 6.—James P——, aged twenty-three, admitted under the care of Dr. Ramskill, suffering from epilepsy of twenty years' standing. Early one morning he had an epileptic fit of an ordinary character, but immediately on the cessation of the convulsion he sprang out of bed and ran about the ward, screaming so loudly as to awake those in distant wards. He was with great difficulty held down while $\frac{1}{50}$ gr. of hyoscine was injected. In two minutes he ceased to scream, and in five he was sleeping soundly. As he was discharged from the hospital next day no further observations were possible.

Case 7.—John O——, aged thirty-three; admitted under care of Dr. Bastian, suffering from epilepsy. While in hospital he suddenly became delusional and maniacal, and required the injection of $\frac{1}{75}$ gr. three times in one day. It did not, however, check his excited condition, but it produced such an amount of muscular relaxation that violence was no longer possible.

Case 8.—Minnie E——, aged seventeen; admitted under the care of Dr. Gowers, suffering from epilepsy of eight

Digitized by Google

years' standing. After having several fits she became violently maniacal. An injection of $\frac{1}{100}$ gr. was given, but as it produced no effect, it was repeated fifteen minutes later. This had the effect of completely quieting her, and making her limbs quite limp, but did not produce sleep.

Case 9.—Harold W——, aged seventeen, admitted under the care of Dr. Beevor, suffering from hysterical contraction and complete anæsthesia of the right arm. The contracted hand did not relax during ordinary sleep, but it did under the influence of an anæsthetic. On one occasion he became very excited and violent after hypnotism. An injection of $\frac{1}{100}$ gr. of hyoscine was given him, and during the sleep and muscular relaxation which followed not only was there opening of the contracted hand, but a prick or pinch on the arm was followed by a movement of the arm away from the irritant, showing a return of sensibility. After the effect of the hyoscine had worn off the old condition of matters was restored.

II.—CASE IN WHICH HYOSCINE WAS GIVEN AS A SUBSTITUTE FOR MORPHIA, THAT DRUG BEING INADMISSIBLE.

William S——, aged twenty-four, formerly a sailor, who had acquired the opium habit, was admitted under the care of Dr. Hughlings Jackson for neuralgia of the arm, which appeared to commence in the cicatrix of an old injury in the thumb. Removal of the cicatrix produced no relief; antipyrin, bromides, and chloral had no effect on the pain, and opium was inadmissible. Hyoscine was therefore given subcutaneously, at first in a dose of $\frac{1}{100}$ gr.; later $\frac{1}{75}$ gr. was required. This was sufficient during several weeks to procure four or five hours' sleep every night.

III.—IN THE STATUS EPILEPTICUS.

Minnie F——, aged sixteen, admitted under the care of Dr. Hughlings Jackson suffering from left hemiplegia and epileptic fits, which always commenced on the left side, both being probably due to a cortical lesion. One evening she had a succession of such fits, with no appreciable interval. After she had been in this condition for three hours, $\frac{1}{75}$ gr. of apomorphine was administered subcutaneously. This produced copious emesis, but the convulsions continued unchecked, and as there was no improvement at the end of three quarters of an hour, $\frac{1}{100}$ gr. of hyoscine was injected. The convulsions at once became less violent, and ceased altogether within five minutes. It is difficult to judge how far the result was due solely to the hyoscine, but its apparent effect was sufficiently striking to suggest its trial in such cases in future.

IV.—CASES ILLUSTRATING THE OCCASIONAL UNPLEASANT EFFECTS FOLLOWING THE USE OF HYOSCINE.

Case 1.—James H——, aged fourteen years and a half, admitted under the care of Dr. Gowers for epilepsy. Hyoscine was given by the mouth in doses which had been increased until he was taking $\frac{1}{60}$ gr. three times a day. No effect was produced on his fits, but he became strange in his behaviour. He looked bright and rational, but was very restless, trying to leave the ward, and wander he knew not where, saying he heard two voices, one advising a good course, and the other an evil one. His pupils were widely dilated, and his accommodation was paralysed. He returned to his usual condition when the effects of the hyoscine had worn off.

Case 2.—Henry H——, aged thirty-three, admitted under the care of Dr. Gowers, suffering from a condition of spastic paraplegia, due to myelitis. Hyoscine was given in the hope of lessening the rigidity, in doses of $\frac{1}{100}$ gr. subcutaneously every night, increased afterwards to $\frac{1}{75}$ gr. After three of the larger doses there was excessive dryness of the mouth, dimness of sight, and delirium with double consciousness. No effect was produced on the muscular spasm.

We have also had the opportunity of observing its effects (usually negative) on a number of other chronic nervous diseases, but as they were mostly isolated cases they are passed over for the present. In our hands the drug never failed to act as a prompt and powerful sedative in cases of mental excitement, and in none of these cases were there any unpleasant after effects. This agrees with the much larger series of observations published in the *Berlin. Klin. Wochenschr.* by Dornbluth (No. 9, 1888) and Eugen Key (No. 50, 1888). They found it "a certain, rapid, and effective sedative, especially in cases in which there was much violence and excitement." In cases of excitement a large dose is more easily borne, and $\frac{1}{100}$ gr. appears to be a safe initial hypodermic dose for an adult. If no effect is produced in half an hour, a second dose of $\frac{1}{200}$ gr. may be given. In other cases of chronic nervous disease a smaller dose is prudent, $\frac{1}{300}$ gr. being given at first and gradually increased. When given by the mouth, at least double the dose given above is required to produce the same effect.

ON THE

EXTENSION OF THE FŒTUS DURING THE SECOND STAGE OF LABOUR.

BY G. ERNEST HERMAN, M.B.LOND., F.R.C.P.,
OBSTETRIC PHYSICIAN TO THE LONDON HOSPITAL, PHYSICIAN TO THE GENERAL LYING-IN HOSPITAL; AND

CHARLES GOULLET, M.R.C.S., L.R.C.P.,
HOUSE PHYSICIAN TO THE GENERAL LYING-IN HOSPITAL.

RECENT observations by German obstetricians have shown that during the second stage of labour the advance of the fœtal head takes place by extension of the fœtal trunk, and consequent elongation of the long axis of the fœtus; not by the pressure of the uterus on the fœtal breech, driving it down, but by the pressure of the uterus around the fœtus, straightening it out. These observations have not yet found their way into English text-books, nor, so far as we know, have they been confirmed in this country. We have therefore thought it worth while to test their accuracy. Litzmann[1] noticed that during a pain the fundus uteri reached higher than during relaxation; and observed seventeen cases in which, up to the time at which the head was distending the perineum, the fundus uteri occupied the same position with respect to the umbilicus as at the beginning of labour. He suggested that this might be part of the normal mechanism of labour; but, in the paper quoted from, did not speak as if satisfied that it was so. Schröder and Stratz[2] ascertained that the measurement between the breech and the vertex with the spine flexed is less than that with the spine extended, by, on the average, more than two inches; and that there may be more than four inches difference between the measurements. Therefore if, in labour, extension of the trunk take place, the head may advance to this extent while the breech remains stationary. They have shown by measurement that this extension takes place: that the distance between the breech and the vertex of the fœtus increases during the passage of the head through the pelvic cavity by an amount such as extension of the trunk would produce. They point out that the flexed attitude of the fœtus before labour is not due to compression by the uterine wall, for the child is usually freely movable in the uterine cavity; and when the child lies in an abnormal position the shape of the uterus is altered in correspondence to that of the child. They explain the extension during the second stage of labour by saying that the body becomes extended, because the contraction ring is drawn up over it, and the fœtal trunk can only pass through this by becoming extended. Hence there is a time during which the head advances, while the breech remains stationary. Hoffheinz[3] has made observations in the Königsberg Clinic to test this point. He measured in 100 cases the distance between the upper border of the symphysis pubis and the fundus uteri. He found that the distance between these points was actually a little longer when the head was distending the perineum than when it was in the pelvic brim. He measured also the distance between the fundus uteri and the most advanced point of the fœtal head, and found that during the second stage of labour this distance was increased by upwards of four inches; an increase more than can be accounted for, according to the measurements of Schröder and Stratz, by extension of the spine. He believes that during the birth of the head the breech ceases to be in contact with the fundus, and the feet take its place. He explains the extension of the spine by the contraction of the uterus in all its dimensions, the resistance to the advance of the child causing the contracting uterine body to pull up the cervix

Digitized by Google

uteri; and this resistance, together with the extension of the child, causes the body of the uterus to be pushed higher up at the time when resistance is greatest—that is, when the perineum is on the stretch. His observations were made in the intervals of pains. During the pains he thinks the uterus is pushed up still higher; in this respect following Litzmann.

In this communication we record measurements made in the General Lying-in Hospital to verify the statements of the writers above quoted. All the measurements were made, with callipers, from the upper border of the symphysis pubis to the fundus uteri, during the intervals of pains. The first measurement was taken when the presenting part was engaging the brim, the second when distending the perineum:—

No.	Presentation.	Parity.	Height of fundus, head or breech in brim.	Height of fundus, head or breech on perineum.
1	4th, cranial	1	11 inches	11 inches
2	1st, ,,	1	11½ ,,	11½ ,,
3	1st, ,,	1	10¾ ,,	10¾ ,,
4	1st, ,,	1	10½ ,,	10½ ,,
5	1st, ,,	1	11 ,,	10¾ ,,
6	2nd, ,,	1	11 ,,	11 ,,
7	1st, ,,	1	12½ ,,	12½ ,,
8	3rd, ending 2nd cr.	1	11½ ,,	11½ ,,
9	1st, cranial	1	11 ,,	11 ,,
10	4th, ending 1st cr.	3	10 ,,	10 ,,
11	1st, cranial	1	9 ,,	9 ,, (8 mos.)
12	3rd, ending 2nd cr.	7	10 ,,	10 ,,
13	1st, cranial	1	10½ ,,	10½ ,,
14	1st, ,,	4	7½ ,,	7½ ,, (7 mos.)
15	2nd, ,,	3	10½ ,,	10½ ,,
16	1st, ,,	1	10 ,,	10 ,,
17	1st, ,,	7	10 ,,	10 ,,
18	1st, ,,	1	10½ ,,	10½ ,,
19	3rd, ending 2nd cr.	1	10¾ ,,	10¾ ,,
20	1st, cranial	12	10½ ,,	10 ,,
21	1st, breech	1	10½ ,,	10½ ,,
22	1st, ,,	1	10½ ,,	10 ,,

It will be seen that in no case was the difference greater than half an inch. In all but three of the twenty cases of vertex presentation there was no difference at all. Of those three exceptions, in No. 20 the measurement was half an inch less when on the perineum; in No. 5, a quarter of an inch; and in No. 4, an eighth of an inch.

Measurements were also taken in two cases of breech presentation. In No. 21 the distance between the two points was a quarter of an inch less when on the perineum; in No. 22 it was half an inch less. A few cases were also measured during a pain, the head distending the perineum; in these there was an increase in the measurement varying from an eighth to a quarter of an inch.

In order to guard against any mistake, nearly all the cases were measured two or three times. These measurements, taken with those quoted from other writers, justify the assertion that whether the head or the breech be the presenting part, extension of the fœtal spine is a constant and essential part of the mechanism of the second stage of labour.

Harley-street, W.

DIPHTHERIA AND ACUTE LARYNGITIS.

TWO CASES OF TRACHEOTOMY, AND DEATH RESULTING FROM SUCKING THE TUBE IN ONE INSTANCE.

BY CHARLES ROBERTS, M.R.C.S., L.S.A.

THE following cases present points of interest from the rarity of the operation having to be performed successively in private practice in so short a time, and also from the melancholy sequel to one of the cases. The following are the facts:—On March 28th last I was asked to see, in consultation with Mr. Barry of West Drayton, a little boy aged six years, the son of Mr. C. J. Moore, surgeon, of Yiewsley, who was at that time away from home. The child was suffering from diphtheria, the first symptoms having showed themselves three days previously. On the 29th the membranous deposit had evidently extended to the larynx, and there was croupy breathing, with some dyspnœa. On the 30th the breathing was fairly good, and there were no urgent symptoms. On the 31st, however, the dyspnœa became more urgent, and it was evident that unless relief were given suffocation would ensue. Accordingly, at 4 P.M., the child having been placed under chloroform by my assistant, Dr. Charpentier, and assisted in the operation by Mr. Barry, I opened the trachea and inserted the tube, thereby giving immediate relief, and subsequently several hours of refreshing sleep were obtained. In the early part of the following morning difficulty of breathing was again experienced, and on my arrival at 9 A.M. I found the tube almost completely blocked by false membrane. I immediately removed the inner cannula, and the child at once breathed freely. During the day the tube became blocked on several occasions, and the inner cannula had to be repeatedly removed and cleansed. That night Mr. Moore arrived home, and thinking greater freedom to the breathing would be given removed the inner cannula altogether. The outer cannula then became blocked, and in order to give relief he insisted on sucking the tube in spite of remonstrance from Mr. Barry, who was present at the time, and this he continued to do at intervals until the child's death, although I and others added our remonstrance to that of Mr. Barry. The only precaution he took was to wash out his mouth with a solution of permanganate of potash. The child died on April 3rd, three days after the operation, death being due to exhaustion and impeded respiration; the exhaustion was intensified from the fact that during the last four days the muscles of deglutition were paralysed, and he resisted all attempts to introduce nourishment into the stomach by means of a tube, and the only way of supporting him was by means of nutrient and stimulating enemata.

On April 4th Mr. Moore complained of his throat being sore, and on examining it I noticed the commencement of diphtheritic deposit on both tonsils, and in spite of active treatment this rapidly extended until it covered both sides of the fauces, soft palate, and uvula, which latter became greatly œdematous. Mr. Moore, who was in bad health and suffering from a dilated heart, with œdematous swelling of the legs, rapidly became exhausted, and in spite of all nourishment and stimulant that could be given suddenly expired on the evening of April 7th from failure of the heart's action, six days from the date of having first sucked the tube, and three from the first appearance of diphtheritic deposit.

It will be remembered that I performed tracheotomy on Mr. Moore's child at 4 P.M. on March 31st, and on my arriving home at 5.30 I found an urgent message to attend another child, a girl aged eight years (who was suffering from acute laryngitis) as the parents thought it could not live long. On arriving at the house I found that the symptoms which had been relieved three days previously had returned, and that the child was in imminent danger of suffocation; therefore, with the sanction of the parents, Dr. Charpentier placed the child under chloroform, and I opened the trachea and inserted the tube. The symptoms were so urgent that the child ceased to breathe, and after the introduction of the tube artificial respiration had to be resorted to before animation was restored. For a time the child breathed better, but both lungs became congested, and on the night of April 1st she had several convulsive attacks from which she never rallied, but died on April 2nd, two days after the operation.

Remarks.—Both cases show the value of tracheotomy in prolonging life, for without it the children would undoubtedly have died on the day these operations were performed, whereas one survived three and the other two days. In the first case paralysis of the muscles of deglutition was an unfortunate complication, as it cut off all means of supporting the child by nourishment and stimulants; otherwise the case might have had a different result, for the child was strong and healthy and made a gallant fight for life, and towards the end of the case the bronchi were almost if not quite clear of diphtheritic deposit. An annotation appeared in THE LANCET of April 20th on the death of Mr. Moore from sucking the tube, and I quite agree with the advice given: "We cannot too strongly impress on surgeons and nurses to avoid such a method of clearing a blocked tube." I look upon such a procedure as simply suicidal; and immediately I was told in the presence of Mr. Moore what he had done, the remark burst from me "You are a dead man," and unfortunately my prediction proved only too correct. In THE LANCET of April 27th a letter from a correspondent, "W.," appeared justifying Mr. Moore's rash act on the ground that it was analogous to a person "who can swim trying to save a fellow-

Digitized by Google

creature from drowning by jumping into deep water. A more weak and illogical argument I have seldom seen put forward. In the latter instance, when rescuer and rescued have both landed, there usually is an end of the case, and the drowning person does not require to be rescued every few hours, as was done in this case by Mr. Moore repeatedly sucking the tube. And again, when the heroic act of the swimmer is over, there is no fear of deadly inoculation working in the system, disease developing in a few days, and death within a week. This case is instructive as to the period of incubation in diphtheria; the tube was sucked for the first time at 11 P.M. on April 1st, and the first symptoms of the disease showed themselves at 6 A.M. on the 3rd, at which time he expressed his opinion to his wife that he had contracted the disease, as he felt unwell, and his throat was sore; so that the period of incubation by inoculation through the mucous membrane may be taken at thirty hours, but the diphtheritic deposit did not manifest itself until twenty-four hours later.

Uxbridge.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A CASE OF DYSENTERY TREATED BY INJECTIONS OF SULPHATE OF COPPER.

By W. EASBY, M.D.

THE case narrated in THE LANCET of Aug. 31st by Mr. Hepburn reminds me of a case where injections of sulphate of copper were most successful. The patient, J. O——, aged fifty, was a thin, spare man. He lived in the Cambridgeshire Fens, and in his young days had suffered from ague. The water-supply to his house was very bad; the usual drinking water was rain water kept in a wooden tub, and when this ran short that from the dykes was used. I first saw him on Dec. 31st, 1876; he had all the symptoms of a smart attack of dysentery; these continued for a week, when he was much better. On Jan. 14th, 1877, he had a relapse, but improved by the 20th. On the 21st I heard he was worse, and was passing a lot of blood, and had much tenesmus. I at once prepared an injection of sulphate of copper, 10 gr.; tincture of opium, 1 dr.; and 4 oz. of water. On reaching the house I found him lying in a small pool of blood. He informed me this had been going on all night, and the tenesmus was unbearable, bringing away blood and mucus. I well oiled a large long gum-elastic catheter, and with a finger in the rectum passed it as far into the bowel as it would go, which was at least fifteen inches; through this the copper solution was injected from a small brass syringe; it caused no pain; and in the evening the tenesmus was relieved, and very little blood had passed. On the 22nd he was decidedly better, but more blood in the stools than I liked, so the injection was repeated, and again on the 23rd; and from this date he recovered rapidly. My treatment prior to the copper injection was bismuth, gallic acid, a full dose of powdered ipecacuanha; but nothing gave such rapid and permanent relief as the copper and opium. The diet was purely milk. I have not had such a bad case as this in an adult since, but in children several; and here the same treatment proved successful.

Peterborough.

A CASE OF TETANUS.

By R. A. JAMIESON, M.A., M.D., M.R.C.P.,
CONSULTING SURGEON TO THE IMPERIAL MARITIME CUSTOMS IN CHINA.

IN the case here briefly reported there was a singular lack of proportion between the phenomena induced, rapidly culminating in death, and their exciting cause. The patient had had no contact with horses directly or indirectly, and no case of tetanus had ever been treated in the ward where she lay.

A Chinese woman, aged fifty-one, field labourer, ruddy and well nourished, was admitted to St. Luke's Hospital for Chinese under my care on July 26th, 1889. For seventeen years she had had a slowly growing, somewhat pear-shaped tumour on the posterior surface of the right thigh, just below the gluteal fold. The tumour had attained the size of a melon, was freely movable on the fascia, and was quite indolent. Its apex was ulcerated, the result of native treatment by plasters, but this ulceration already dated back to nearly a year. The growth and surrounding parts were extremely filthy. As a preliminary to removal, frequent washing was ordered, the ulcerated surface was sprinkled with iodoform, and the tumour was enveloped in freshly carded oakum. This was the only treatment that the patient received. The weather was extremely hot, the thermometer in the shade marking 100° F. on July 27th and 28th. The patient ate well and slept well, and in every respect, except as regarded the local trouble, was in excellent health. On the evening of the 28th she sat for a couple of hours outside the ward door on a staircase through which a strong current of comparatively cold air was blowing. Next morning (29th) she complained of pain and stiffness in the muscles of the neck and inability to depress the lower jaw. The incisors could not be separated to a greater distance than three-quarters of an inch. During the day tetanic spasms in the trunk and limbs occasionally occurred. These became more frequent during the night. On the morning of the 30th the lower jaw was immovable. Temperature obtained in axilla 105·8°, and no doubt higher. Spasms became more frequent, but were never violent. Temperature rose to 107°, delirium lasted for about an hour, giving place to unconsciousness, death following in an hour and a half, thirty-six hours after the onset of the symptoms.

Shanghai.

A CASE OF DOUBLE POLYDACTYLISM, DOUBLE HARELIP, COMPLETE CLEFT PALATE, AND DOUBLE TALIPES VARUS.

By F. MARSH, F.R.C.S.,
SURGEON TO THE QUEEN'S HOSPITAL, BIRMINGHAM, ETC.

THE following case presents features of teratological interest. A male infant, three days old, was brought as an out-patient to the Children's Hospital, Birmingham, on Sept. 9th, 1889. On each hand there was a supplementary digit attached by a narrow pedicle to the skin over the ulnar side of the head of the fifth metacarpal bone. Each digit, including the nail, was perfect, and almost equal in size to the adjoining little finger. Both hard and soft palates were fissured, the cleft in front being distinctly to the left of the mesial line. The double harelip and the talipes were severe examples of their respective deformities. In other respects the infant was normal and fairly nourished. It was, however, very feeble, and died from malnutrition on Sept. 16th. The mother had previously given birth to nine children, all of them healthy and in no way deformed. Careful inquiry failed to elicit any history of polydactylism in any branch of the family. No "maternal impressions" had been received, the deformities being both unexpected by, and inexplicable to, the mother.

The case is an unusual one, if not a unique one, combining as it does deformities the result of three different causes: (1) the extra digits due to developmental excess; (2) the harelip and cleft palate due to developmental arrest; (3) the talipes varus due to fœtal malposition or mechanical pressure in utero.

Birmingham.

GLYCERINE OF BORAX IN THE DIARRHŒA OF INFANTS.

By E. MANSEL SYMPSON, M.A., M.B. CANTAB.

IF we regard infantile diarrhœa as due to the excessive fermentation of food in the intestinal canal causing irritation and a catarrhal condition of the intestinal mucous membrane, it seems reasonable to look for a remedy to act both on the cause and effect. Glycerine itself is an antiseptic of no mean order, and relieves the congestion and pain of inflamed piles, chiefly mucous surfaces, while every

Digitized by Google

mother knows the virtues of glycerine of borax when applied to the mucous membrane of the mouth. So it was no great step to introduce it further into the alimentary canal. Whether fed from the breast or brought up by hand, the motions of patients with diarrhœa infantum were like curds of milk, sugesting that the irritated intestine had hurried its contents on as quickly as possible. Again, they were very foul-smelling, suggesting great fermentation. Therefore the glycerine of borax has to do two things: to act as an antiseptic to prevent excess of fermentation in the stomach and intestines, and to soothe the mucous membrane thereof in passing over it. I have found it answer capitally; the children like it, it lessens the griping pains, it renders sweet the offensive motions, and it stops the diarrhœa. One case died while under this treatment; the child was seven months old, had had diarrhœa two days, and was utterly worn out when I saw it. But I suppose there always will be cases which come under our notice too late for cure. I give it as follows: Glycerine of borax, twenty minims; tincture of orange, three minims; distilled water to one drachm. To be given every one, two, or three hours, according to the severity of the case or the age of the patient.

CORNUA CUTANEA.

By H. HOLDRICH FISHER, M.B.

HORNS growing from the skin are considered somewhat uncommon; the following case came recently under my observation in a labouring man of sixty-five years. The horn projected for an inch from the lower lip on the right side; it had a blunt extremity, was firmly adherent, and the skin around at the base superficially ulcerated. He stated that it had first appeared as a small warty growth three years ago, had slowly increased, and after being cut off with a razor on two occasions seemed to grow again quicker each time. On the opposite side of the same lip was what appeared to be another warty growth in its early stages. He was in the habit of holding his clay pipe this side, and not on that from which the horn grew. There were no glands enlarged, and the patient was in good health. The treatment consisted of removing the horn, together with the part of the lip that it was attached to, by a small V-shaped incision under cocaine locally injected, and bringing the edges together with one or two sutures.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Procemium.

CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, VICTORIA PARK.

A CASE OF ABSCESS OF THE BRAIN COMPLICATING DISEASE OF THE LUNG; NECROPSY; REMARKS.

(Under the care of Dr. SAINSBURY.)

CASES of abscess of the brain, secondary to suppuration elsewhere, but independent of symptoms of general pyæmia, constitute, according to Dr. Gowers, about 10 per cent. of all cases of cerebral abscess. Of this group the primary focus of suppuration is most commonly to be found in the lung. The pathology is somewhat mysterious, and though in the present instance no new light is thrown on the subject, yet the comparative infrequency with which such cases arise makes it advisable that they should be recorded. For the notes of the case we are indebted to Dr. Chaplin, house physician to the hospital.

W. J——, aged forty-six, an engine driver, was admitted into Victoria Park Hospital on July 8th, 1889, under the care of Dr. Harrington Sainsbury. He complained of spitting of blood and phlegm, pain in the right side of his chest from the level of the sixth rib to the right hypochondrium, and considerable emaciation. There was no history of lung disease in his family. He had been in Egypt for three years, and had enjoyed excellent health until December, 1888. In April, 1889, he went through an attack of pleurisy in the right chest. In May he began to expectorate tenacious yellow phlegm, and at the end of June hæmoptysis set in and continued without intermission until his death.

Upon admission he was coughing up daily about three-quarters of a pint of grumous blood, mixed with phlegm and shreddy elements. His temperature was 101·2°, and he complained of pain at the base of the right lung. The following physical signs were made out at his right base:—Impairment of percussion note from the level of the angle of the scapula to the base, vocal vibrations diminished, breathing sounds very feeble, and vocal resonance diminished and altered in quality. An exploring trocar was introduced and some dark grumous blood withdrawn, mixed with pus. In spite of all treatment the hæmoptysis continued without abatement. On Aug. 1st he complained of the fingers of his right hand becoming at times firmly closed, the spasm lasting from a few seconds to a minute before the fingers could be unclosed and stretched out. On the 8th, at about 2.30 P.M., the patient was found unconscious. The pupils were unequal, the left being widely dilated. There was no conjugate deviation of the eyes. The right arm and leg were in a state of clonic spasm. The muscles of the face and neck upon the right side were tonically contracted, and he passed his urine and fæces under him. After remaining in this state for an hour and a half he suddenly had an epileptoid fit. Both pupils were now dilated. The eyes deviated to the right side, and there was tonic spasm of the right leg and arm, giving way after a few seconds to clonic spasm of that side, and then to general clonic spasms of both sides of the body. During the intervals of the fits the pupils were noticed to rhythmically contract and dilate. The patient continued to have the fits until 2.40 A.M., having fifty-five in all. He remained unconscious until he died at 11 A.M. on Aug. 9th.

The necropsy was performed by the pathologist, Dr. Wethered, who found the following morbid appearances:—The dura mater was firmly adherent to the vault of the skull. The arachnoid space contained a large excess of fluid. The anterior convolutions of the left side of the brain were somewhat flattened and soft to the touch. On cutting into the left frontal lobe, a small abscess, filled with pus, about the size of a filbert, was seen situated in the posterior part of the third frontal convolution and extending to the lower part of the ascending frontal convolution. The abscess wall was thin and injected, the brain substance around being œdematous, but otherwise healthy. At the base of the right lung, which was adherent to the diaphragm and chest wall, was an irregular cavity the size of a large walnut, with thin, smooth walls and filled with grumous bloody material. The cavity was near the posterior surface of the lung; it communicated with a bronchus, and a small pulmonary aneurysm of the size of a pea projected into it. This aneurysm contained a soft clot and opened into an artery. The lung substance around the cavity was congested and œdematous. There was nothing else of a morbid nature in the lungs except a few adhesions over the left apex. There was no disease of the valves of the heart.

Remarks by Dr. SAINSBURY.—The following points are, I think, worthy of note. The occurrence of a smooth-walled cavity, in communication with a bronchus, at the base of the lung; the adherent state of the base of the lung to the chest wall and the diaphragm; and the absence of disease elsewhere in the lungs, saving a few adhesions over the left apex; the arising of this state of things in sequence to a distinct attack of pleurisy in April, 1889; the absence of any history of the sudden expectoration of pus such as might have indicated the presence of pneumonia (along with the pleurisy) and its termination in abscess; the absence of any history of lung disease in the family. The conclusion is, I think, fair that the cavity was bronchiectatic in nature. It will be observed, however, that the base of the lung, though adherent by its surface, was not cirrhotic. The occurrence of severe hæmoptysis as a symptom in bronchiectasis is, I think, uncommon. Its dependence upon an aneurysmal dilatation is noteworthy. The expectoration was not fetid; this is probably to be explained by the constant oozing of blood into the small

Digitized by Google

cavity, which led to the frequent expulsion of the contents of the cavity—a washing out not wholly desirable. Next we have the occurrence of an abscess in the left cerebral hemisphere, which we must take to be secondary to the lung disease, without there having been any symptoms of blood poisoning. The temperature throughout was but little raised, the maximum rarely exceeding 100° F., the minimum touching or falling slightly below normal; there were at no time rigors or sweatings.

TAUNTON AND SOMERSET HOSPITAL.

DISLOCATION ON TO THE DORSUM ILII IN A CHILD; REMARKS.

(Under the care of Mr. FARRANT.)

DISLOCATIONS at the hip-joint are of such rarity as to make them interesting, especially when they occur in childhood, for in children the femur is very easily broken, yielding to a force which would otherwise be sufficient to produce rupture of ligaments and displacement. Malgaigne gives a list of fifty-one dislocations of the femur, but out of these only one was under the age of fifteen years. Sir Astley Cooper collected a series of fifty-six dislocations of this joint; in forty-five of these cases in which the age is mentioned, only seven were under twenty years of age. Hamilton gives the proportion of dislocations of the hip-joint in children (i.e., under fifteen years of age) as fifteen out of a collection of eighty-four. For the notes of this case we are indebted to Mr. W. B. Cosens, house surgeon.

Chas. T——, aged seven, was taken to the casualty room of the hospital on July 26th, 1889, the father saying that the boy's "hip was out." At the same time he gave the following history of the injury. Whilst playing at a "three-legged race," his right leg being fastened by means of a handkerchief to his companion's left leg, he stumbled and fell, his left leg being under, the other boy falling across him. He felt something "go," and on attempting to rise found his leg powerless. On admission the following was his condition. He complained of pain over the left hip-joint, and the left thigh was semi-flexed, adducted, and rotated inwards, the ball of the great toe almost resting on the dorsum of the right foot; the great trochanter was above Nélaton's line. On attempting to extend the leg, the boy immediately cried out with pain. The head of the femur was easily felt, resting on the dorsum ilii. The dislocation was easily reduced by flexing the thigh on the abdomen, rotating outwards, and quickly bringing the leg down to a straight line with the body, the head of the femur entering the acetabulum with an audible click. A long outside splint was applied and the boy kept in bed for three weeks.

Remarks by Mr. FARRANT.—I think little apology is needed for recording the case owing to the extreme rarity of dislocation of the hip-joint in young children. Erichsen mentions two cases in his book on Surgery—one on to the pubic bone in a child aged one year and a half, another on to the dorsum ilii in a boy of six. In THE LANCET of 1868 Mr. Powdrell recorded a case in which the head of the femur was displaced into the foramen ovale at the age of six months, and reduced by manipulation. The case recorded above has done well, there being good movement in the joint at the end of three weeks, and, at the end of six weeks, the boy was running about as if nothing had happened.

BRECKNOCK INFIRMARY.

A CASE OF TRAUMATIC TETANUS; RECOVERY; REMARKS.

(Under the care of Mr. D. V. REES.)

WE publish below the account of a case of traumatic tetanus which came on five days after the receipt of injury, and terminated, rather more than four weeks after its commencement, in recovery. The symptoms throughout appear to have been of subacute character, excepting for the attacks which affected the muscles of the glottis. In the editorial remarks to a case successfully treated by[1] nerve excision and chloral hydrate, we mentioned at some length various methods of treatment which had been employed, and drew attention to those which had proved most successful. Of these, chloral hydrate was at the head of the list, the larger proportion of recoveries having followed its exhibition alone, or associated with other remedies. The effect produced by the salicylate of eserine will be noted with interest. For the following account we are indebted to Mr. J. R. J. Raywood, late house surgeon.

T. V——, aged seven years, was admitted on May 7th, 1888. He was a fairly well-nourished boy, and had never had any serious illness. On April 30th he burnt his left leg with a hot flat-iron just below and external to the head of the fibula; the wound inflamed and suppurated, though not sufficiently to prevent his going to school. On May 5th his father noticed the boy's face "drawn," and he complained of stiffness about his jaws, and had some difficulty in opening his mouth. On May 6th he was seen by the visiting surgeon, who found his condition as follows. Risus sardonicus and trismus well marked, muscles of back, neck, and abdomen rigid and fixed with occasional tonic spasm; bowels confined; tongue coated with thick white fur; pulse 80 per minute; temperature 98·8°; intellect clear; he spoke in a whisper, and screamed and called out when the spasms came on. There was a small wound just below the head of the left fibula about two inches long by an inch and a half wide, granulating and suppurating. He was ordered five grains of calomel at once and five grains of bromide of potass in two drachms of water every four hours. When admitted on May 7th all the above symptoms were present, and there was also occasional spasm of the glottis and opisthotonos. The spasms came on very often, during which time the heart beat tremulously and the whole body was bathed in perspiration. A hypodermic injection of salicylate of eserine ($\frac{1}{100}$ gr.), every three hours, was now ordered, and the following mixture: ten grains of bromide of potass, half a drachm of the syrup of chloral hydrate, in half an ounce of water; to be taken every three hours, the medicine being given an hour and a half after each injection. Diet, beef-tea and milk.

May 8th.—Slept at intervals during the night; several very severe spasms of the glottis, all the other symptoms the same. Bowels confined. Temperature 99°. To have an enema of warm water when necessary.

9th.—Sleeps continually except when spasms come on; takes nourishment well but mouth firmly fixed and nearly closed. Temperature 98·6°; pulse 76; respiration 17. In the evening had a severe spasm of the glottis, which lasted nearly two minutes, but rallied after warm fomentations to the chest and neck. The injections of salicylate of eserine to be increased to $\frac{1}{60}$ gr. every three hours; the mixture to be continued as before.

10th.—The spasms are less frequent; he is very drowsy; breathing slower; some stertorous breathing, and he sneezes frequently; pupils minutely contracted; the wound on the leg is healthy and dressed with zinc ointment. Temperature 98·8°; pulse 78.

11th.—Sleeps nearly all the time. Spasms not so frequent. Still sneezes frequently; this is followed by a general tonic spasm of muscles of abdomen, back, &c. Pulse weak and compressible. The risus is not so marked, and he opens his mouth a little better. Temperature 98·8°. To have two ounces of brandy daily.

12th.—Two injections were omitted during the night. The spasms are more frequent again; the other symptoms continue the same. Bowels act every day after an enema. Temperature 98·8°.

13th.—Much improved. Rigidity of muscles not so great. Temperature 98·6°.

15th.—The spasms only affect the back and the face now. Pulse strong. Takes nourishment well. Temperature 98·6°.

18th.—Rigidity of abdomen still continues. Can open his mouth widely. There are a few moist râles at both bases of lung. Temperature 99·4°. To omit medicine, and inject eserine ($\frac{1}{80}$ gr.) three times a day. Wound quite healed.

19th.—Risus and trismus almost gone. Had only three slight spasms to-day. Temperature 98·6°; pulse 86; respiration 19. Took a little solid food to-day.

30th.—Can sit up in bed without assistance. Is taking food well. Omit the injection.

June 7th.—All rigidity has now gone. To get up.

17th.—Left to-day quite well, and has gained in weight considerably.

Remarks by Mr. RAYWOOD.—The success attending the treatment of this case is worthy of notice, for in nearly all the published cases of tetanus eserine was either not given, or if given it was not pushed until the physiological effects

[1] Mirror of Hospital Practice, THE LANCET, vol. ii., p. 114, 1889.

Digitized by Google

of the drug were shown. Here its action was most marked; for although the bromide and chloral may have assisted to recovery, yet these drugs had no direct control over the spasms, for whenever a dose of eserine was omitted the muscular spasms were stronger and more frequent, and no relapse occurred when the bromide and chloral were discontinued. It was also noticeable that the temperature was never above 99·4°.

Medical Societies.

OBSTETRICAL SOCIETY OF LONDON.

A MEETING of this Society was held on Wednesday, Oct. 2nd, Dr. A. L. Galabin, President, in the chair.

A report was read on Mr. Stewart Pollock's specimen of Dermoid Ovarian Tumour from a mare, exhibited before the Society in July.

Dr. WILLIAM DUNCAN exhibited: (1) A Dermoid Ovarian Tumour; (2) an Ovarian Cyst; (3) Pyometra and Pyosalpinx, with Suppurating Kidney and Thrombosis of the Renal Artery, from a patient subject to syphilitic disease of the rectum.

Dr. J. PHILLIPS showed some Blue Urine from a case of cyanuria.

Dr. CULLINGWORTH exhibited a Hæmatosalpinx from Rupture of a Varicose Vein in the Fallopian Tube.

Mr. WOODLEY SLYMAN brought forward an Acardiac Fœtus with Rudimentary Heart.

Dr. J. SHAW exhibited a Uterine Douche.

A Contribution to the Anatomy of the Pelvic Floor.—A paper on this subject was read by Dr. HERMAN, in which measurements were detailed which show the great normal variations in the conformation of the parts which form the floor of the pelvis. It was shown that the projection of the pelvic floor varies from none at all to as much as two inches, and that in healthy nulliparæ the distance between the coccyx and anus, the length of the perineum, the distance between the fourchette and the symphysis pubis, and the length of the vagina, are subject to wide variations. It was pointed out that since these variations exist in healthy nulliparæ, peculiarities observed in parous women should not be assumed to be changes due to childbearing unless it has been ascertained that they were not present previous to pregnancy. The clinical importance of these anatomical variations in their bearing on the liability to rupture of the perineum and to prolapse, the adjustment of pessaries, and some forms of dyspareunia and sterility, was indicated.

On the Changes in the Pelvic Floor which accompany the Slighter Degrees of Prolapse.—This subject was also introduced by Dr. HERMAN, who described the descent of the pelvic floor which takes place during effort in health and is morbidly increased in prolapse. Measurements were given which showed that this descent in health probably does not exceed three-quarters of an inch. This descent takes place partly by stretching of the sacral segment of the pelvic floor in an antero-posterior direction, and partly by its recession downwards and backwards from the symphysis pubis, a movement which implies transverse stretching. In the antero-posterior stretching the perineum and the part posterior to the anus take part to about the same proportionate extent. This normal descent of the pelvic floor is accompanied with descent of the uterus into the vagina to the extent of about five-eighths of an inch. These changes may be morbidly increased and their relative extent morbidly altered. The descent of the pelvic floor may exceed two inches. This morbid increase of descent of the pelvic floor may be present without increased descent of the uterus into the vagina. In other cases it may be accompanied with descent and protrusion of the anterior segment of the pelvic floor, with or without the uterus. In such cases, when a protrusion at the vaginal orifice has taken place, further effort increases this protrusion, but does not increase the descent of the sacral segment of the pelvic floor. Backward displacement of the uterus is often present without more descent of the uterus or of the pelvic floor than is present in most healthy women; but in most cases of backward displacement of the uterus the descent of the uterus and pelvic floor is increased. Backward displacement of the uterus is not associated with shortness of the vagina. Although the symptoms of descent are usually relieved by suitable mechanical support, yet the amount of descent of the uterus or of the pelvic floor is not the measure of the severity of the symptoms. There may be symptoms with slight descent in some patients, much descent without symptoms in others, and in the same patient the symptoms may be present at one time and absent at another, although the amount of descent has not varied; showing that the symptoms are conditioned more by the state of the nervous system than by the local mechanical changes.—Dr. GRAILY HEWITT considered that Dr. Herman deserved much credit for his analysis of the phenomena observed in cases of slighter degrees of prolapsus. The subject was of vast importance, for the effects of so-called minor displacements, though not dangerous to life, destroyed all enjoyment of it. The patient's sufferings often became intensified, so that in later years serious impairment of the uterine functions often followed neglect of the symptoms of minor displacements in their earlier stages. Dr. Hewitt was glad to find himself in agreement with Dr. Herman on many points in reference to descent of the uterus and its effects in producing suffering. He believed, however, that in these cases the principal cause of the suffering was the exaggeration and intensification of the version or flexion of the uterus more frequently associated with descent of that organ. Descent of the uterus pure and simple was rare, but descent accompanied with flexion or version was very common. In estimating the effects of the displacement it would be necessary to find out how much of the suffering was due to the mere descent and how much to the increased flexion or version. So far as backward displacement was concerned, Dr. Herman noted that descent was thereby increased. Nothing had been said about anteflexion. Dr. Hewitt believed that anteflexion not yet rigidly set in that shape, the uterus being still fairly movable, might be regarded as not abnormal. The case was quite different when the organ was sharply bent forwards, the fundus low down, and the uterus firmly resisting alteration of shape and position. Dr. Herman noted several cases of cystocele. In these cases the anteflexion was probably an important causative element. Descent of the pelvic floor was chiefly important because it brought about increase of flexion, and consequent increase of discomfort.—Dr. HERMAN regarded anteflexion as one of the natural shapes which the uterus might assume. He had investigated the frequency of anteflexion in the healthy uterus, and laid the results before the Society.[1] Vedeler had made a similar research, with substantially the same result—namely, that acute anteflexion was very common in health. No one else had investigated the question. Backward displacements caused symptoms in but a small minority of cases; not by any effect of the bending of the uterus, but by the torsion and pressure on the broad ligaments which returned the blood from the uterus. In a case described that evening a patient was kept for two months in hospital, and all her symptoms went away, yet the retroflexion remained exactly as it was on admission, showing that it was not an important feature of the case.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

THE opening meeting of the eighth session of the above Society was held on Friday, Oct. 4th, in the board room of the West London Hospital.

Mr. KEETLEY showed some Loose Cartilages removed from two knee-joints; also a portion of a Kidney crushed off by a waggon wheel, and removed through a lumbar incision.

Mr. PERCY DUNN showed some recent additions to the Museum of the West London Hospital.

The PRESIDENT (Dr. H. Campbell Pope) then gave his address on "The Beginnings of Disease." He began by congratulating the members of the Society on its increasing success, and then proceeded to state what was to be understood by the term "beginnings of disease." He quoted Dr. Andrew's remark in his Cavendish lecture, that "all disease begins, mediately or immediately, in the environment," and went on to speak of Dr. Harry Campbell's statement, in his work "On the Causation of Disease," that "the environment is in the last resort the sole cause of

[1] Transactions, vol. xxiii.

Digitized by Google

disease." This work, however, discussed the general origin of disease, whereas the President wished to consider the question of disease as affecting the individual. The best way of studying the interactions of organism and environment was by getting to understand the nature of these factors, and how they react on one another. As an example of the influence which environment brings to bear on organism, the case of the Bach family was cited, whose adaptation to musical surroundings during four generations culminated in the production of the great genius, John Sebastian Bach. The effect of environment on structure, both as to development and quality, and in intra-uterine life and after birth, was then discussed. The part which heredity plays in the formation of structure having been referred to, the speaker came to the consideration of the production of disease by the want of harmony between structure and environment. This point was illustrated thus: "Let S (structure) represent a literary man of slight muscular development, and let E (environment) represent his accustomed sedentary work and mental surroundings. We will suppose him to have inherited an average structure, and that his immediate surroundings are free from glaring sanitary defects. We shall here get a fairly normal interaction and a fairly healthy life. But place this S (the literary man) in a fresh E, let him take his place in the blacksmith's smithy for a week, if he has not by the end of that time strained his cardiac valves, or ruptured himself, he has in all probability, from the exposure to great variations of temperature, contracted some catarrh or inflammation. Here S + E = abnormal life or disease. It is, then, best to speak of this as abnormal – E, so far as that particular S is concerned; we thus get S + abnormal E = disease. Similarly, by reversing our example, and putting the blacksmith in the student's library, we might in the same time find him suffering from hæmorrhoids, or exhibiting signs of inhibitory paresis, such as restlessness and the use of unparliamentary language, even if mental alienation had not already occurred. But, on the other hand, these structures are also abnormal to their changed environment—that is to say, S and E are *both* abnormal the one to the other." Having spoken of "inevitably abnormal environments," Dr. Campbell Pope concluded by indicating the bearings of his subject on the ordinary work of the practitioner of medicine.

Reviews and Notices of Books.

Inorganic Chemistry. By IRA REMSEN, Professor of Chemistry in the Johns Hopkins University. London: Macmillan and Co. 1889.

WE close this book with a feeling of disappointment. Professor Remsen had given us so excellent an introductory text-book of organic chemistry, that we hoped to find in this larger manual an important contribution to scientific literature; but in spite of many merits, it is impossible to regard it in this light. It may be briefly described as an elementary primer swelled into a large octavo book of over 800 pages. The style is lucid, the illustrations fairly good, and the printing and paper excellent, but the whole of the matter might with advantage have been condensed into half the space. The periodic arrangement has been adopted, but not followed slavishly, whereby some practical inconveniences are avoided. The plan bears some resemblance to that of the second volume of Miller's "Elements," inasmuch as general principles and laws are for the most part interspersed in the text instead of being treated in preliminary chapters, as in Graham's well-known and admirable "Elements." Thus we find Diffusion described partly under Hydrogen (p. 45) and partly under Silicon (p. 421), and the little that is said on thermo-chemistry is similarly scattered. There are some advantages in this system, but they only accrue when the book is read straight through, and they are balanced by the disjointed manner in which important theories are presented.

The chief faults of the book are the very insufficient space devoted to physical phenomena; the almost entire absence of references to larger works, original memoirs, and the names of discoverers; and the sketchiness and insufficiency of the chemical facts given. Too much space has been devoted to structural formulæ, which are moreover printed with quite unnecessary diffuseness, and the result has been that the accounts of important elements and compounds are often very incomplete. It was part of the author's plan to exclude physics as much as possible, but the exclusion, or rather the compression, has been carried too far, and has marred the usefulness of the whole book. Thermo-chemistry is one of the most important adjuncts to modern chemistry, and it is almost as important to know the calorific equivalent of a reaction as to know the symbols which represent the change of matter. Yet we find nothing here but the baldest generalities, and the heats of combustion, even of such elements as carbon and phosphorus, are not given. The whole subject of spectroscopy, not wholly unimportant to chemistry, is dismissed in two pages of loose description, in which not a word is said of the identification of spectra by wave-lengths. Electrolysis is disposed of in a page, and the account of it is so meagre as to be misleading. Then, again, with regard to specific gravity and solubility. Surely these physical peculiarities do not lie outside the province of chemistry, and yet we are not told the specific gravities of diamond, graphité, sulphur, iodine, or white arsenic, to take a few haphazard illustrations. Of iodine we are told that it "dissolves slightly in water"; of hydriodic acid, that it "dissolves in water in large quantity"; and of white arsenic, that it is "difficultly soluble in water." We could quote many similar instances, but it is enough to say generally that the book is loosely compiled, not original in any true sense, and inferior to less pretentious manuals already well known.

An Appendix of nearly 100 pages gives directions for the performance of experiments in illustration of the matter of the text. Some few of these are novel and good, but the majority are well known, and many hackneyed.

The Elements of Vital Statistics. By ARTHUR NEWSHOLME, M.D. Pp. 326. London: Swan Sonnenschein and Co. 1889.

THIS volume is a valuable and much needed addition to statistical literature. It lays down clearly the principles on which inquiries in the branch of vital statistics should be conducted, and points out the errors into which persons ignorant or regardless of these are likely to fall. It is often said that "figures will prove anything," and so they will at any time, if used dishonestly, and very often if used honestly but ignorantly. The latter we believe to be the more frequent cause of the erroneous results deduced from numerical investigation. It is with a view to lessen as far as possible this source of error that Dr. Newsholme has compiled this excellent guide-book. The work may be said to consist of three divisions: 1st, the method of collecting and arranging the necessary numerical data; 2nd, the use to which, and the manner in which, these may be applied; and, lastly, a brief but clear statement of some of the chief fallacies too often met with in medical statistics. Under each he lays down the principles on which the work should be done, and illustrates these by examples taken, in most instances, from the Registrar-General's Reports. In the last chapter he gives a concise summary of the more important statistical errors, to many of which he had already called attention. These he classifies under the two heads of "Fallacies of Observation" and "Fallacies of Inference," and treats under the following subdivisions:—(1) Errors from paucity of data; (2) from inaccuracy or incomparability of data;

Digitized by Google

(3) errors in comparing total deaths in successive years; (4) errors in regard to averages; (5) errors in connexion with average strength; (6) fallacies of hospital statistics; (7) errors from the composition of ratios; (8) fallacies arising from stating deaths in proportion to total deaths. Each of these is illustrated by one or more striking examples, which we do not quote, in the hope that our readers may for themselves carefully study the facts there stated. To those who are not experts in statistical science we recommend this work as containing a clear statement of the principles of vital statistics, intelligible rules for the collection and application of numerical data, and a useful caution against the errors into which, through ignorance, honest inquirers are but too likely to fall. Dr. Newsholme quotes the four chief rules of Quetelet, that great master in statistical science, as "worthy to be held in remembrance—(1) Never have preconceived ideas as to what the figures are to prove; (2) never reject a number that seems contrary to what you might expect merely because it departs a good deal from the apparent average; (3) be careful to weigh and record *all* the possible causes of an event, and do not attribute to one what is really the result of a combination of several; (4) never compare data which have nothing in common. Were these rules constantly followed the science of statistics would be much more respected than it is, and the value of its results would be greatly increased."

New Inventions.

INSTRUMENTS FOR THE TREATMENT OF RECTAL DISEASE.

WE have received from Messrs. Burroughs, Wellcome, and Co. specimens of two instruments designed by Dr. Ward Cousins for use in the treatment of rectal disease. We have given them a long trial, and, as they answer the purpose for which they were invented, can recommend them to the profession. They are (Fig. 1) an ointment intro-

FIG. 1.

ducer, designed for the efficient introduction of ointments within the sphincter, so that they may be the better distributed over the mucous membrane of the rectum. "It consists of a very smooth anal tube, a cylindrical receptacle for the ointment, and a vulcanite piston. The ointment is projected through the anal tube, at the end of which there are perforations, by compressing the piston with the finger." Fig. 2 represents the anal injector, and is intended for the

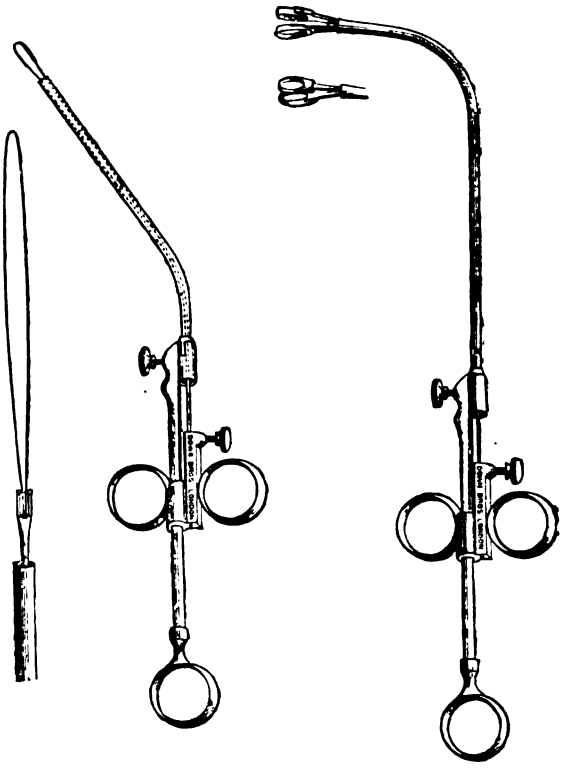

FIG. 2.

introduction of fluid applications to the rectum. It is made with a somewhat similar anal tube, but has a ball syringe attached to it, which will hold a measured quantity of fluid. It will be found very useful for the administration of the glycerine enema.

NEW NASAL SNARE AND LARYNGEAL CURETTE.

THE nasal snare is known as Professor H. Krause's, of Berlin. The special advantage is that the wire loop is a short one, and is attached to the end of a rod running in the cannula and fixed to the handle by a screw, so that the loop is easily adjusted, and when broken is easily replaced. Moreover, it can be at once re-protruded by pushing down the handle. It will be immediately seen that there is an immense saving of time and trouble. It is also very powerful.

The polypus can be cut through or dragged away. The cannula is movable, so that to the same handle can be fitted the laryngeal curette. This is valuable in removing tuberculous infiltrations. There are two terminals—one acting antero-posteriorly and one laterally. Messrs. Down Brothers of St. Thomas's-street, S.E., have made the instruments for me. I have found the nasal snare so valuable that I am sure many will be glad to know of it.

Weymouth-street, W. CHARTERS J. SYMONDS.

ANDERSON'S COLLEGE MEDICAL SCHOOL.

To the Editors of THE LANCET.

SIRS,—In your issue of Oct. 5th, and under the heading "Scotland (from our own correspondents), Glasgow," I have with much surprise read the following statement:—"The teachers in Anderson's College Medical School are understood to be favourable to the admission of women to their classes, and to be ready to undertake the management of '*mixed*' classes of male and female students." In reference to this I feel it to be my duty to say that I am strongly opposed to *mixed* classes; and, further, that I am strongly opposed to the admission of women to our *New* Medical School under any circumstances at the present juncture.—I am, Sirs, yours truly,

A. M. BUCHANAN, M.D.,
Professor of Anatomy and Dean of the Medical Faculty of Glasgow, Oct. 8th, 1889. Anderson's Coll. Med. School.

QUARANTINE.—The British representative at Alexandria telegraphed, on Oct. 5th, that Bombay had been released from quarantine.

THE LANCET.

LONDON: SATURDAY, OCTOBER 12, 1889.

COMPETITION in medical education is an excellent thing, but it has its inconveniences and unseemlinesses as competition has in other spheres. The truth of this proposition is illustrated particularly by what is going on just now at Glasgow. Since the removal of the ancient university of that city westward and the erection of the Western Infirmary in 1874, the connexion of the University with the Glasgow Royal Infirmary, with its grand clinique of 542 beds, has ceased. This latter is the hospital in which more historical work has been done of late years than perhaps in any other in the world. It was as surgeon to this hospital that Sir JOSEPH LISTER wrote in THE LANCET his first articles on Antisepticism in Surgery, which have revolutionised the art; and it is here that Dr. WM. MACEWEN has performed those brilliant feats of cerebral and osseous surgery the mere description of which last year at the meeting of the British Medical Association in Glasgow led the audience to rise to their feet and cheer the modest surgeon. No wonder that Glasgow medical men sighed when they thought of the comparative effacement of this magnificent institution, and longed to bring it into greater efficiency and prominence as a centre of medical and surgical teaching. It is all very well to write, as some writers do, as if hospitals were injured by being turned to educational uses. On the contrary, they are perfected. The medical officers act under public criticism. The students are ready to help in dressing and in "clerking" the cases, and everything is done systematically and with a minuteness that is not possible without a good medical school. The absence of such a school and the monopoly of the Glasgow University, with its smaller Infirmary, have led the managers of the Royal Infirmary and others to put forth a great effort to establish an efficient College in connexion with the Royal Infirmary, in which not only Medicine but all the other Faculties should be recognised and taught. There has been, since the migration of the University westward, a Royal Infirmary Medical School; but it has not thriven, and the attempt to which we refer is to create a College really worthy of the clinical field of the Royal Infirmary and of other appliances and laboratories connected with it. The effort is most laudable if somewhat ambitious. But for the moment, in the medical world at least, it has excited more criticism than praise. This criticism has reference, chiefly, to the way in which appointments, have been made in the new school called the St. Mungo's College. It is a bold thing for any English critic to venture to interfere in a Scotch fight. Medical school disputes in Scotland are perhaps the most inflammable of all controversies. In Edinburgh men have become more philosophical now, but these fights used to divide universities from colleges, and one set of university professors from another. And, if tradition speaks truly, on a celebrated occasion one eminent Scotch surgeon lay in wait to horsewhip another. But distance in regard to such conflicts is not altogether a disadvantage, and we cannot be indifferent to that which affects the fair name of Medicine and its efficient teaching in such a city as Glasgow. Scotland teaches nearly as many men in Medicine as England does, and a large proportion of them are destined to practise in England. It concerns us to know the genesis of medical schools and the guarantees for their efficiency. We must not speak about other Faculties, but content ourselves with the medical department, and the way in which its chairs have been filled. Even so, we can only state the principal facts, which have been the subject of severe articles in the press, both lay and medical. We ourselves have received a number of highly interesting letters on both sides of this controversy, the drift of which only we can hope to give to our readers, together with the impressions they have left on our minds.

The chief promoters of the St. Mungo's College are a party well known in Glasgow as University Reformers, men who object to the monopoly of higher education by the University, who wish to develop extra-mural genius and merit, and who have naturally seen in the Royal Infirmary a means of attaining their end. Some of their hostility may perchance have a tinge of personal feeling and dissatisfaction. Even in the purest reformers there is apt to be an admixture of such baser elements. But it is not necessary to deny high and disinterested motive to such reformers, with whom we have considerable sympathy. When the appointments to the new College had to be made there were clearly two ways of making them open to the governors: one by advertisement and public candidature and the selection of the fittest; the other by a committee of selection, whose choice should be submitted for ratification to the governors. The latter was chosen. The result is a *casus belli*, which fills the Glasgow medical world with charges of favouritism and jobbery and self-promotion. It is impossible to avoid mentioning one gentleman who is credited with much responsibility in these matters—Dr. D. C. MCVAIL. Dr. MCVAIL is too strong a man to mind having his whole share in these transactions discussed, and we have too much admiration for his individuality and force of character to shirk our duty of criticism, the more so as with perfect candour he has placed before us his statement of the case. Dr. MCVAIL long before the incorporation of the College was a University reformer. Since its incorporation he has become a governor of the College; and previously to his being appointed as a physician, he was a manager of the Royal Infirmary. Moreover, he was already one of the academic committee to which was delegated the selection of professors and lecturers, and he seems to have actively negotiated with men as to the acceptance of particular chairs. Nothing can at first sight be more indefensible than such a mode of selection. Dr. MCVAIL has, as we should expect, the courage of his position, and he defends the selections, including his own appointment as professor of clinical medicine and as extra-physician to the Royal Infirmary, though he had not before been on the staff of that institution. He defends the mode of appointment on three grounds: Firstly, and mainly, that by the articles of incorporation, the managers were to provide, *inter alia*, for "the absorption and continuance of the Glasgow Royal Infirmary

Digitized by Google

School as a part of St. Mungo's College. This they liberally interpreted to mean the taking over of the staff of the school to the College. Secondly, it was represented that many of the most indispensable men, especially in the Faculty of Law, though willing to take chairs offered to them, would not respond to advertisements. Thirdly, that the Governors were influenced by precedent in such matters, and that the precedent to follow was that of the Scottish Universities who never advertise, but elect as patrons.

The opponents have shown some considerable flaws in these arguments, though we admit there is much force in them in spite of Dr. MCVAIL having profited much by his own reforms. A reformer must often benefit inevitably by the alterations which he himself has mainly brought about. Witness the case of the late Mr. FIRTH and the government of London. It is to be said in Dr. MCVAIL'S favour that though he has gained *status* as a hospital physician and a professoriate in clinical medicine, the chair is not one which carries any honorarium, so that financially at least he is not a gainer. Moreover, it is quite intelligible that the movement which he mainly represents and which owes its force to him, would collapse if his energy and interest were not in some way engaged. It is undoubtedly unseemly that he appears as appointing himself to offices and wards, especially when a man like Dr. WALLACE ANDERSON, with years of service at his back in the school, which Dr. MCVAIL says they had to incorporate, is left out in the cold. But, on the other hand, we must remember that the Governors of St. Mungo's College are really responsible, and that they include many of the leading public men of Glasgow and the West of Scotland. A perfectly open election would perhaps have been preferable; but there is nothing more cruel and unjust than to invite scores of candidates by advertisement when the selection of certain persons is a foregone conclusion. The fact is this, that the new University Bill gives a new chance to educational reformers in Scotland, who have the power to make use of it. In doing so they incur the suspicion of interested motives and methods. They must accept this fact. The justice of the suspicion must be tested by time and results. We shall be glad if the great hospital of Glasgow becomes so identified with medical education as to support its historical fame, either by affiliation with the University or as a worthy and stimulating rival. This will not be an easy achievement, and if the reformers are actuated by merely personal motives they will soon fail.

NO subject has recently excited more interest or provoked more discussion than extra-uterine gestation. Without, therefore, proposing to write a treatise on the subject, we think it may be well to indicate a few of the points of the greatest importance, and especially to call attention to the present condition of our knowledge of the subject. The fact that the fœtus is not always in the uterus has of course been known for a longer time than the history of medicine extends; indeed, the extreme danger of the condition was sufficient to ensure attention to the subject. It was not, however, till 1859 that KUSSMAUL proved that many alleged cases were not extra-uterine, but were due to pregnancies occurring in a malformed uterus. Such a discovery as this has a violently disturbing effect, for it throws doubt on the great majority of cases previously recorded; and from 1859, therefore, records trustworthy in this point of their pathology may be said to begin. It is surprising, however, to observe how jealously every specimen of alleged extra-uterine gestation near the uterus must even now be criticised, to avoid this very error. It may be briefly said that the differential diagnosis depends on the point of origin of the round ligament of the uterus; since this springs from the uterus, and therefore is internal to the tube, a gestation external to its origin must be tubal, internal to its origin, uterine. The condition of the parts, and the absence of special knowledge on the part of the dissector, not infrequently obliterate this landmark and render the determination of the question difficult, if not impossible. The connexion between extra-uterine gestation and hæmorrhage is obvious, and it will be sufficient here to refer to the work of BERMUTZ, who, in 1848, pointed out the differential diagnosis of intraperitoneal hæmatocele and subperitoneal hæmatoma. The connexion between intraperitoneal hæmatocele and intraperitoneal (abdominal) pregnancy, and between subperitoneal (or extraperitoneal) hæmatoma and subperitoneal (or extraperitoneal) pregnancy is also plain. The occurrence of the latter form of pregnancy was affirmed in 1837 by DEZEIMERIS, and has been lately confirmed by Dr. BERRY HART and Dr. CARTER, in two cases, by frozen sections.

Of all the varieties of extra-uterine pregnancy, most is naturally known of the tubal variety; partly because it includes the great majority of cases, and partly because most of the rarer varieties belong to a later stage of pregnancy, and may have been later developments of cases originally tubal. Since tubal cases generally end early in catastrophe, it is only the surviving and developing cases which come under consideration in any other form. Whether this is the whole truth we do not yet know. Knowledge is desired, indeed urgently needed, on some of the following points:—1. What is the relation of extra-uterine cases advanced in pregnancy (*a*) to the tubes, (*b*) to the peritoneum? In cases ending fatally, and therefore alone capable of minute section and dissection, both these questions, especially the former, are apt to be difficult, and even impossible of elucidation. 2. When the placenta appears to have been planted on the intestines, bladder, or uterus, has this been brought about directly or through the mediation of the tube? 3. Are there such things as primary abdominal pregnancies? It has been asserted that there are only two undoubted instances of abdominal pregnancy on record—those of JESSOP and CHAMPNEYS. Of course early cases of abdominal pregnancy would be very helpful; but where are such cases to be found? It must be acknowledged that this fact is significant, and it may turn out that all abdominal pregnancies were originally tubal or tubo-ovarian; but assertions and prophecies do not help matters which must finally be settled by facts. 4. What are to be accepted as sufficient evidences of extra-uterine gestation? It would appear obvious that the answer to this question must be (*a*) presence of the fœtus, (*b*) presence of the placenta. A recent writer states that, out of forty cases, the fœtus could only be found in twelve, the placenta being found in every one. We must, however, point out that in cases of rupture this proof is often extremely difficult. The placenta

Digitized by Google

is a mass of clot, and sections of it show nothing but clot, with spaces which may (or may not) mark the position of the villi. Sections of undoubted placenta show this. What, then, are the proofs in doubtful cases? It is plain that great caution must be exerted in drawing any conclusions or accepting any numerical statements without the exhibition of sufficient evidence. 5. It would be well to know the mortality in (*a*) intraperitoneal hæmatocele, (*b*) intraperitoneal rupture of tubal pregnancies, (*c*) subperitoneal rupture of tubal pregnancies without operation. The difficulties which beset this question and render its answer at present impossible are those of diagnosis. We need only caution our readers against too ready acceptance of such assertions as that the two former are invariably fatal. Indeed this is contrary to experience. Of course (*a*) and (*b*) are more dangerous than (*c*). This proposition is sometimes fortified by an argument in a circle, or begging the question, any recovery from (*a*) and (*b*) being denied as impossible. But it is even asserted that all cases of rupture end fatally without operation, and patients who survive operation are counted as lives saved. There can be no doubt that rupture occurs pretty often without a fatal result, and this arithmetical statement needs revision.

The question of treatment must be reserved for consideration in another article.

MRS. WALLER'S article upon "The Mental and Physical Training of Children" in the current number of the *Nineteenth Century* traverses a wide field, and deals with many topics of which no one will question the importance. The views expressed make no claim to originality, and are practically identical with those enunciated by HERBERT SPENCER in his well-known work upon education. Not the less, however, is Mrs. WALLER'S paper worthy of thoughtful perusal, and probably no one would be more pleased than the writer if her suggestions could be justly regarded as truisms. That a sound physique must take precedence of educational proficiency; that the care and culture of children have higher claims upon reasonable men than the breeding of horses or the training of dogs; that the model nursery is of greater moment than the model farm; that the young mother needs to be soundly instructed in questions of food, clothing, and habit; that the development of the will and the moral faculties must proceed on some recognised principles, and not by caprice and chance;—such are a few of the principles advocated, and the only thing to be regretted is that their advocacy should be still necessary.

"It is really surprising," says the writer, "to see the amount of trouble and pains bestowed upon the proper housing and feeding of horses and dogs, or other domestic animals, while at the same time comparatively little attention is paid to these matters with regard to the rearing of children. Model stables and model kennels abound, while the model nursery is almost unknown. Warming, ventilation, and aspect are subjects which are thoroughly considered in the stable, while as regards the nursery they are generally left for chance to decide, though the health of a child is surely more important than that of a horse or dog." This is only too true, and the explanation of facts so strange is worthy of more than a passing thought. Is it that material conditions are recognised as having a definite and unfailing effect upon the health of the lower animals, and that their not less potent or sure influence upon the human organism is less readily admitted? Or is it that to many men the horse and the dog have a definite monetary value which the child is not felt to possess? Or, lastly, is there a half conscious feeling that the health of the lower animals can be understood by anyone who will take a little trouble, while the health of the human animal is so intricate an affair as to be best left in the hands of the professional adviser? It is likely that each of these reasons has some weight. Mrs. WALLER recommends that two of the best rooms in the house should be set apart for the day and night nursery respectively, and that the importance of sunshine and the evils of overcrowding should be recognised in all the nursing arrangements. She advises that the nursery walls should be painted rather than papered, paint being easily washed and disinfected after the attacks of infectious disease, which in every large family are only too likely to occur. As regards clothing, it is pointed out that in spite of modern improvements in this matter, it is still too much the custom to leave the upper part of the chest and the lower part of the abdomen exposed, and that hence come pulmonary affections on the one hand and bowel complaints on the other. "It is a fact that not only has the child less power of generating heat than the adult, but that it has also a much larger surface in proportion to the mass of its body, and will consequently be far more susceptible to cold. Cold feet cause a large amount of indigestion, and exposure of the large blood-vessels of the thigh during childhood frequently sows the seed of kidney diseases to develop in after life."

Some apt remarks are made upon the question of moral training. "One of the earliest lessons the child has to learn is that it can only have its own way when it is compatible with the comfort and rights of others. ..... As far as possible, a child should be made to feel that punishment is the natural result of his bad action, and not the mere venting of anger and annoyance on the part of the parent or nurse. ..... Let the child find out that bad behaviour in the drawing-room means instant banishment to the nursery; that if he knocks his brother with a stick the result is '*no sticks*'; that, if he refuses to put away his toys one night, he must manage without toys the next night." In these remarks, obvious as they may appear to the less reflective mind, lies, we conceive, one of the most important secrets of moral training. All retribution, to be effective and to carry suasion with it, must possess this character of inevitableness. It must appear to be the direct and necessary, not the arbitrary and fortuitous, result of the delinquent's own act. It must, in fact, serve to impress one of the greatest lessons of life—that as we sow, thus, and in no other way, shall we reap. Mrs. WALLER is decisively against all forms of corporal punishment, a point upon which many of the wisest heads have differed and still differ. Probably the advocates of corporal punishment would not demur to being compared with those who hold the necessity of war. In each case the extreme measure is to be adopted only as a *dernier ressort* when milder measures have failed.

We are disposed entirely to concur in the remarks of the

Digitized by Google

writer regarding the best means of beginning intellectual training. "I should begin the teaching of a child as a favour, not as a task; if he is inattentive, I should by no means insist upon the lesson being done, and so give it the air of a task. It is far better to say: 'I really cannot waste my time in teaching, for I have other matters to do, and if you cannot give me a little attention you may go away. With the natural perversity of human nature, the child immediately becomes anxious to learn, and feels at once that you are doing him a favour." It is correctly laid down that all teaching must proceed from the concrete to the abstract. Sight and touch must, as far as may be possible, do the work of the thinking faculties. To an attentive observer of children, nothing is more striking than their great aptitude for observing and their incapacity for sustained thought or abstract argument. The latter power comes later, but the attempt to develop it prematurely is usually not only futile, but injurious. Educators have too little recognised this principle, and have wearied and perplexed many a young brain to little purpose with such subjects as syntax, parsing, and the like, forgetting that such topics are only less difficult than logic and metaphysics, which no one would suggest as suitable subjects for the very young.

The relative value of the comparative attractions of science and language as vehicles of education is touched upon, but is too great a subject to be more than alluded to here. The classical tongues had their long day of virtual monopoly; science for a time threatened seriously to dispossess them; it seems not improbable that we are on the eve of a time when the value of both will be more generously and less contentiously allowed. Few practical men will deny on the one hand that a perfect tongue such as Greek is an admirable means of mental discipline; or, on the other hand, that even very young children will absorb with avidity facts about the world around them and about their own body—the rudiments of physics, botany, astronomy, and physiology—and be all the better for such knowledge.

WE understand that the Committees of the Senate and of the Convocation of the University of London have, after mature consideration, decided upon the principles of the scheme for the reconstitution of the University on the lines laid down by the Royal Commission, and that its details are well advanced, so that we may expect it to be laid at an early date before the members of the University for their sanction or disapproval. In many respects it will follow the plan of reform put forward by Lord Justice FRY'S Committee, and which was rejected by Convocation after a long debate. If the scheme accords with the recommendations of the Royal Commission, it must contain, as essentials, changes which we cannot but think will be unpalatable to most of the existing graduates, and to which only the fear of the formation of a second university in London, although with different aspirations and powers, could possibly bring them to consent. The transfer of power from the present Senate to a Senate largely recruited from the ranks of the London teachers is a leading feature in the scheme of the Commissioners, and must be accepted as the basis of any new Charter that may be applied for by the University; and, of course, this change is strongly objected to by the teaching bodies outside the metropolitan area. A meeting of representatives of provincial Colleges will be held in Birmingham on Thursday next at 3 P.M., to "arrest the progress of the scheme or to suggest modifications which may have the effect of diminishing its unfairness." The University of London is therefore at once confronted with the difficulty of becoming a Teaching University for London and of retaining its hold on external teaching institutions. Professor LAWSON TAIT, at the inaugural meeting of the session of the Northumberland and Durham Medical Society, made some overtures for the affiliation of the Birmingham Schools of Science and Medicine to the University of Durham, and promised a most absolute and uncompromising opposition on the part of those who had the higher education of the Midlands at heart to the establishment of a Midlands University. But many of those who are interested in the higher, and not in technical medical, education will prefer a Midlands University to an affiliation with a remote university, such as that of Durham, which seems to have been looked on by Professor TAIT as merely a convenient body for giving degrees to Birmingham students. The next alteration which must be made by the University in the spirit of the report of the Royal Commission is in the standard of the medical degrees. All medical teachers in London are unanimous in asking for pass medical degrees for their students, and every university, except the University of London, has granted them on conditions which are not unduly severe. Can a Senate which has prided itself on the stringency and severe character of the examinations for these degrees now bring forward a proposal in antagonism to its past history, and one which will be acceptable both to existing graduates, and to those who are urging the lowering of the standard to an average pass? Sir ALBERT ROLLIT, in his inaugural address at King's College, referred to this dilemma, which he, as a member of the Committee of Convocation engaged in drawing up the scheme, must have felt acutely. "It is to be hoped, however, that the present honour of the London M.D. and M.B. degrees will not be lost to the profession or their standard unduly lowered." The Royal Commissioners have set before the authorities of the University a very difficult problem for solution. We shall be glad if they can accomplish the task, provided that fairness and justice are meted out to the London student. They have to become a metropolitan and local University without offending the teaching colleges in other parts of the kingdom, and to frame a system of examinations for a pass degree of the same standard as the Scotch and provincial Universities, without impairing the honour and value of that which is now granted on very much more exacting conditions.

THE death is announced at Doebling, near Vienna, of Dr. Max Leidesdorf, a well-known authority on brain disease. The deceased, who was in his seventieth year, owned a private asylum at Doebling, where numerous personages of note have been treated, among them the Duchess of Cumberland and Prince Joseph Sulkowski. Dr. Leidesdorf, who was frequently summoned for important consultations on mental maladies in Austria and neighbouring countries, certified Sultan Murad and King Louis II. of Bavaria to be insane.

Annotations.

"Ne quid nimis."

THE CONDITION OF THE BLACKWATER RIVER.

THE polluted condition of the Blackwater stream and the insanitary state of large tracts of the Bagshot sands have been the subject of comment in the pages of THE LANCET for years past. Mr. Haviland referred to it in a lecture published in our columns on a former occasion, and in his communication in our issue of to-day he again directs attention to the matter after having personally inspected portions of the stream. The large area which Mr. Haviland pronounces "a plague-stricken valley" extends even very much beyond the districts he has investigated. Indeed, the greater portion of the low-lying marsh lands of the middle Bagshot sand district is insanitary. The geological formation known as "the Bagshot Sands" (so named from the village of Bagshot, which was till recently the largest village near the centre of the district) consists of three distinct formations, named by geologists (1) Upper, (2) Middle, and (3) Lower Bagshot sands. These are all more or less sandy; but the middle sands are interspersed largely by layers of very tenacious clay, while gravel often caps the upper, and is abundant also in some portions of the lower sands. No two soils can differ more than the Upper and Middle Bagshot sands. While the former is as a rule free from insanitary conditions, the latter is very insanitary indeed, and must be regarded as the source of much of the black filth from which the Blackwater stream derives its name. This black mud is the decomposing dead vegetation which season after season accumulates on the higher lands and filters through the porous sands, till it is intercepted by the impervious clay of the middle Bagshot layer. Here it accumulates till heavier rains wash it by main force to the streams, like the Blackwater, which intersect this district. Within the present generation a large population has collected as offshoots to Wellington College, the Royal Military College, the Staff College, and Aldershot Camp, all of which are unfortunately built on this insanitary Middle Bagshot area. This new and rapidly increasing population adds filth to the Blackwater stream, previously polluted to an insanitary condition. There are persons still living who suffered from malarial fever in this district. Diphtheria is now seldom absent from the Blackwater valley, and is a permanent danger to the boys at Wellington College, to the cadets at the Royal Military College, to the officers and their families at and around the Staff College, to the Camp at Aldershot, and the large civil population necessarily congregated around this military district. Here, as we have before pointed out, we are endeavouring to cultivate our military officers and soldiers to be fitted, by constitutional vigour, to stand against the various climates of our vast Empire, and we are doing it by placing our officers from boyhood to manhood in institutions in and adjacent to what Mr. Haviland describes as a "*plague-stricken valley.*"

SCARLET FEVER IN LONDON.

THE large and steadily increasing number of scarlet fever patients under treatment in the Metropolitan Asylum Hospitals appears to be producing a somewhat false impression as to the prevalence of that disease in London. It is true that since the middle of June, when the number of scarlet fever patients under treatment in these hospitals was 538, the weekly numbers have steadily increased to 1247 on Saturday last, exceeding by 361 the number under treatment at the corresponding date last year. It should, however, be borne in mind that the deaths from this disease have not shown a corresponding increase, and have been continually below the average for the time of year. The annual death-rate from scarlet fever in London during the quarter ending with September last did not exceed 0·18 per 1000, against 0·42 in the twenty-seven large provincial towns dealt with in the Registrar-General's weekly return. The death-rate from scarlet fever in London, which had been 0·40 and 0·22 per 1000 in the third or summer quarters of 1887 and 1888, further fell to 0·18 last quarter, and was scarcely more than half the mean rate in the corresponding quarters of the seven years 1882–88. This low death-rate from scarlet fever, coincident as it is with the large and steady increase of cases under hospital treatment, may be due partly to the prevalence of a mild form of the disease, and partly to the constantly increasing proportion of cases treated in hospital. The proportional case mortality in hospital should throw some light upon the type of the disease. The proportion of deaths from scarlet fever to completed cases (recoveries and deaths) in these hospitals in the three months ending with September, 1888, was 10·8 per cent.; and in the corresponding period of this year the case mortality was 10·6 per cent., or nearly the same. The mortality during August and September last was, moreover, probably unduly raised by the constant increase of admissions, as the case mortality is always highest during the earlier stages of the disease. It may be noted that the deaths from scarlet fever belonging to London in the thirteen weeks ending on Saturday, Sept. 28th, numbered 190, and that they showed the highest death-rates in Mile-end Old Town, Newington, Holborn, Clerkenwell, and Fulham sanitary areas.

BACTERIA AND VIRUS.

THE connexion between bacteria and disease is not explained by the simple fact of the invariable presence of certain microbes in certain diseases, nor by the circumstance that such diseases can be reproduced in animals by inoculations with these microbes. The bacterial theory of disease, like that of fermentation, involves a far larger question. It implies that these parasites are capable of converting the media in which they flourish into chemical substances that have a poisonous action on the body, deranging its normal mechanism and thereby producing various groups of symptoms, and even death. It is well known how of late years attention has been gradually becoming fixed upon the chemical aspect of morbid processes, and there has also been a growing belief in the necessary intervention of bacterial "ferments" to produce the alkaloidal substances known as ptomaines, which are derived from the albuminoid elements, and to which so much has been attributed. Dr. Brieger, whose name is largely associated with this subject, reviewed it in its general bearings in an address delivered at the recent meeting of German naturalists and physicians at Heidelberg. He pointed out (*Berl. Klin. Woch.*, No. 39) how the domain of "infective" disease was widening at the expense of diseases due to nutritional and nervous changes, and proceeded to show that whereas in nature we have everywhere abundant evidence of bacterial chemistry, so in disease analogous effects due to the agency of these minute organisms are to be observed. That the normal vital processess are accompanied by the production of a large number of substances of the aromatic series, such as skatol, indol, carbolic acid, &c., was pointed out by Mischerlich and Hoppe-Seyler; and these products of putrefaction were to be found in the living body or its excreta in greatest amount when the vital powers were much impaired. But these substances are of far less importance than the basic products of bacterial life, which Brieger distinguishes into the highly poisonous *toxine* and the non-poisonous *ptomaine;* the latter, it may be remembered, having been first discovered by Selmi in the cadaver.

Digitized by Google

Toxine (using the term in a generic sense), he showed, is produced even in the primary act of digestion, for peptones injected under the skin of animals often produce symptoms of poisoning; and the action of pepsin or fibrin produces a poison that causes paralysis and even death in some animals. The number of similar products formed in the further course of digestion is very large; the most poisonous of such derivatives of albuminoid disintegration being neurin (derived from cholin) and methyl-guanidin (from creatin). The poisonous effects of certain articles of diet—all the cases of mussel-poisoning, sausage-poisoning, &c.—are to be attributed to like principles due to bacterial ferments. Dr. Brieger then showed that up to a certain point various forms of toxine had been obtained from pathogenic bacteria—as the staphylococcus aureus, streptococcus pyogenes, typhoid bacillus (typhotoxin), cholera bacillus, anthrax bacillus, tetanus bacillus, and others, and then referred to the subject of auto-intoxication, which has been so well studied by Bouchard and Gautier. It was shown that there was a parallelism between the fermentations excited by pathogenic bacteria and those of putrefactive organisms, and that a disease—e.g., typhoid or tetanus—owes its specific characters to the special toxine thereby produced. A further development of the subject lies in the explanation of immunity, and the idea that the products of one kind of microbe may neutralise or destroy the effects of other toxines. Infection thus comes to be really an "intoxication," and the susceptibility to infection to depend on the greater or less tolerance of the body to the poison. The whole facts of protective inoculation accord with this view, so that it may be expected that in time immunity may be obtained through the agency of the ptomaine and toxine of the disease concerned. Then, said Dr. Brieger, will the therapeutic aims of medicine—the establishment of rational and therefore of specific measures of cure—be attained; and this can only be by a close connexion being formed between pathology and chemistry.

COMPULSORY GAMES IN SCHOOLS.

THE parents of boys at our public and private schools have been pouring forth their grievances on the hardness of compulsory games. The fact is schoolmasters are at their wit's ends to know how best to occupy their pupils in the intervals of class. One set of parents—and in this they are supported by the medical profession—claim as a right that their sons should not be subjected to more than seven or eight hours class work in the day. The rest of the time not occupied in eating or sleeping has to be provided for, and there appears to be but one way of doing it, and that is by some kind of compulsory athletic exercise. No one can have visited any of our public schools on a half holiday without being struck by the sight of several hundred boys playing cricket in summer, or football in winter. Here, it appears to us, may be witnessed instances of the maximum of good and the minimum of evil in our public school system, which is the admiration of every foreign country. It is only when these compulsory games are carried to extremes that parents have any right to complain. Games are essential to the discipline of every school, for boys of ordinary go and vigour, with a view of increasing their vigour by the physical exercise to which any boy of ordinary constitutional powers has a natural propensity. There are public schoolmasters of high repute who hold that a certain standard of physical vigour is essential in a boy if he is to reap the full advantage of a public school training, and in those instances where this standard is not, and cannot be attained, it would be far better for parents to realise the fact, and not subject a boy to a career for which he is not fitted, and which can only end in their disappointment and probably their boy's ruin. A large number of our public school boys are quite unfitted intellectually and physically to benefit by a public school course of training, and the system is discredited by the inadaptability of such boys to the requirements of a public school. There are "loafers' in class as well as in the playground, and such boys should be removed from among large numbers to private schools where individual attention in work and recreation can be given to them. Such boys are to be pitied rather than blamed, for they cannot bear the jostling of the playground, nor have they the aptitude for the hurry and smartness of the public school class and would be better away from both.

REPORTED DEATH UNDER NITROUS OXIDE.

WE published last week a brief report of a fatality which occurred in Edinburgh, resulting, unhappily, in the death of Lady Milne, but until full particulars of the sad event are before the profession it would be premature to criticise the case in detail. It has been demonstrated by Dr. Dudley Buxton in some careful experimental work that nitrous oxide *per se* does not possess any depressant action upon the heart, but rather tends to strengthen and slow cardiac force and rhythm. When the dentist, however, both operates and administers the gas, there is always a danger lest the anæsthesia should not be profound enough, and so the patient, feeling the pain while in the post-narcotic stage, incurs the risk of reflex inhibition of the heart, so liable to appear at that time. Intent upon his own work, the extractor cannot watch his patient as he should be watched, and thus grave perils are incurred. It is most deplorable that so safe an anæsthetic as nitrous oxide has been proved to be, should be blamed for fatalities which, while occurring under nitrous oxide, are not directly due to that agent. All skilled anæsthetists seem to agree that there is more danger to be apprehended from an insufficient supply of nitrous oxide than from pushing that agent to profound narcosis. Owing to the very transitory period of unconsciousness obtained by nitrous oxide every second of time is valuable, and hence the peril in allowing one individual to undertake a double function—to administer gas and extract teeth—arises not only from the impossibility of operating and watching the patient simultaneously, but also from the loss of time incurred in exchanging the face-piece &c. for the extracting forceps.

THE HOURS OF TRAMCAR AND OMNIBUS MEN.

THE hour (1.30 A.M.) at which the recent meeting of tramcar and omnibus men was held constituted in itself an instructive protest against the system of overwork which forms the chief grievance in this department of labour. The working day, as now arranged, is of uncertain duration. We have reason to believe that the maximum statement of seventeen hours and a half represents an extreme, but not an exaggerated, or even perhaps unusual, condition. It may be regarded as the type of a full day for omnibus and car drivers. The short periodic intervals of rest at a terminal public-house cannot be supposed to lessen materially the strain of the day's work. Of the six and a half remaining hours a certain proportion must necessarily be occupied in going to and from home, in dressing and undressing, and in such meagre domestic civilities as are quite unavoidable. Consequently the sleep of the carman, however sound, must be short indeed, barely sufficient for the easiest liver and quite inadequate for men employed in irksome and continuous duty. It is true that the work done is not very severe, that it allows of free movement, fresh air, and of sufficient, if not regular, nutrition. Thus far it is wholesome. On the other hand, there is hardly any relaxation

Digitized by Google

in the vigilance, alertness, and concentration demanded for the exercise of responsible functions, discharged as these often are in spite of bad weather, fog, and the numberless petty worries of street traffic. Serious accidents are happily not common, a fact which may best be attributed to the slow rate of speed allowed, but the tension of such long-continued effort cannot be otherwise than prejudicial to the men employed. It is out of keeping with the customs of labour in other callings, and it is of very dubious public benefit. A change is clearly called for, and in this connexion the demand of the men—a working day of twelve hours, even if accompanied, as it naturally would be, by a diminished wage—is by no means unreasonable. We would be disposed to ask for the further concession of Sunday as a day of rest at least every other week. Under such altered conditions we are certain that the duties now performed by the *employés* would be better done, and probably with no serious loss, if any, to the tramway and omnibus companies. It is to be hoped that both masters and men will have the sense to adjust this matter with due regard to their mutual interests, and without a needless trial of strength amid the risks, the frictions, and follies of a strike.

CENTENARIANISM IN ENGLAND AND IRELAND.

WE recently called attention to some statistics of centenarianism in Ireland contained in the annual report of the Registrar-General for Ireland relating to the year 1888. We pointed out that the deaths of 208 reputed centenarians during last year in Ireland stood out in strong contrast to the number usually registered in England and Wales, averaging about 65 per annum. The English report shows that a remarkably large proportion of the deaths of reputed centenarians are recorded among the Celtic population of Wales, and we were therefore prepared to find a proportionally large number of cases of reputed centenarians among the recorded deaths in Ireland. Bearing in mind that the last census in 1881 showed that 25 per cent. of the Irish population aged upwards of five years could neither read nor write, and that another 16 per cent. could only read, it may naturally be concluded that very hazy and indefinite information as to age prevails among a considerable proportion of the Irish population. It was not, therefore, the number of cases of reputed centenarianism which excited surprise and incredulity, but the statement that "further inquiry having been made, it was ascertained that the ages of the centenarians as given in the records were in *every instance confirmed.*" A letter from a correspondent takes exception to our incredulity of the fact that 208 established cases of centenarianism were recorded in Ireland last year, the above-quoted statement notwithstanding. We did not intend to throw any doubt on the fact that each of these cases had been investigated, but such an unwonted result of investigation of cases of reputed centenarianism appeared inevitably to suggest a desire for information as to the precise nature of the investigation. The late Mr. Thoms published *in extenso* the result of his investigation concerning thirty reputed English cases, only four of which were satisfactorily established as cases of centenarians. The late Dr. William Farr, in the thirty-fourth annual report for England, remarked: "The difficulties attending investigation of cases of reputed centenarianism are no doubt considerable, but the question is one of scientific importance." Any light therefore that can be thrown on the nature of the investigation which was held to establish the authority of the 208 cases registered last year in Ireland would possess undoubted value. Our correspondent, moreover, asserts that in our remarks we took no account of the fact that the Irish population contains a larger proportion of elderly persons than does the English population, a fact to which attention was called by Dr. Grimshaw in his able address as president of the Sanitary Science Section of the Congress of the Sanitary Institute in Dublin in 1884. The census in 1881 showed that 106 per 1000 of the Irish population were aged upwards of sixty years, while in England and Wales the proportion was only 74 per 1000. Aware of this fact, however, we were careful to test the relative proportions of centenarianism in England and Ireland in such a manner as to eliminate this disturbing influence. We found that of the recorded deaths in Ireland of persons aged upwards of seventy-five years, 12·5 per 1000 in 1888 were stated to be those of centenarians; while from the last published English report (that for 1887) we found that of the recorded deaths at these ages only 1·1 per 1000 were those of reputed centenarians. The obvious and natural conclusion from these facts would be that the ages of deceased persons are more incorrectly stated in Ireland than in England. But then we are met with the statement that all the Irish cases were investigated and established. The subject is, as Dr. Farr said, one of such scientific interest, that we should be glad to have full particulars concerning the nature of the investigation to which the Irish cases in 1888 were submitted.

ISOLATION OF THE INFECTIOUS SICK AT SALFORD.

SOME time since we drew attention to the deadlock which has occurred at Salford in connexion with the isolation of infectious diseases, and although both scarlatina and diphtheria are now somewhat widely prevalent in the borough, matters do not seem to be any more promising than formerly. The Wilton Hospital has been purchased by a railway company, and, at any moment, a six-months notice to quit it may be served on the Corporation. It is described as adapted to receive sixty-one patients; but even then the sick would not have the advantages attaching to a properly constructed and efficiently ventilated institution. At the present moment it contains about 110 patients. The Corporation, having decided to erect a new hospital, and having secured the sanction of the Local Government Board to the scheme proposed, are now the owners of a site of some thirteen acres of land at Ladywell; but, owing to opposition in the Council itself to its use, the mayor and several prominent members of the Sanitary Committee resigned their seats on that body, and another Committee, containing the principal dissentients, was appointed some months ago to ascertain what alternative arrangements could be made. As yet none have been entered into, but, in view of the present emergency, efforts are being made to induce the authorities of Monsall Hospital to receive the Salford cases; and it is suggested that this hospital, which already serves for all the existing requirements of Manchester, and professes also to be available for a large number of other sanitary districts, should also be made permanently available for Salford; and this although it is a hospital which in epidemic times receives small-pox, in addition to the other specific fevers. It has also to be remembered that, under the new scheme sanctioned since Dr. Tatham assumed office in Manchester, that city will for the future have additional claims on Monsall by sending its enteric-fever patients there also. The demand now made upon the hospital is therefore an extensive one; and the governing body are taking time before they give a final answer to Salford's new hospital committee. Another scheme foreshadowed is that a pavilion should be erected in connexion with the Pendlebury Hospital for Sick Children, to which Salford could send infectious cases. As to this Mr. Walmsley, M.R.C.S., an alderman of the Salford Corporation, expresses his belief that the Pendlebury authorities will never commit "such a fatal mistake"; and we must admit that the adoption of such a step on any such scale as

Digitized by Google

materially to relieve Salford of its infectious cases would be one calling for the gravest consideration. But, under any circumstances, we trust that the present state of affairs, which Mr. Walmsley describes as disgraceful to the borough, will speedily be brought to an end by some satisfactory solution of a difficulty which otherwise bids fair to become very pressing.

COMPULSORY VACCINATION.

A MEETING in condemnation of the Compulsory Vaccination Act was held last week at Guildford, at which the usual misstatements as to the effects of vaccination were made. Thus the audience was told that in Sheffield during the last small-pox epidemic "eight cases, nurses and attendants in a hospital, who had all been revaccinated, occurred, and there were two deaths." Turning to Dr. Barry's report, we find that in the Sheffield small-pox hospitals there were 140 persons in contact with the sick; in addition, there were 21 other persons not themselves necessarily in actual contact with the sick, though in constant communication with attendants on small-pox cases. Of these 161 persons, 18 (11·2 per cent.) had suffered from small-pox prior to 1887–88, and none of the 18 contracted small-pox during the present epidemic; other 62 (38·5 per cent.) had been vaccinated in infancy only, and of these 6 (9·7 per cent.) contracted small-pox, and one died. The 5 non-fatal cases were slight in character. Of the remaining 81, all of whom had been successfully revaccinated, *not one contracted small-pox*. It is not matter for surprise that people who cannot check the statements made at the Guildford meeting are misled. The effects of similar teaching in Leicester are well known, and the inhabitants in that town seem bent upon preparing their children for fatal disease. We learn that during the quarter ending Sept. 29th only 30 children were vaccinated in Leicester out of 1250 births.

SAILORS' RATIONS.

A DISCUSSION has lately been carried on regarding the sufficiency, both as to quality and quantity, of the food supplied on board Her Majesty's ships, and its effect on the health and discipline of the crews. Whilst many affirm that the dietary is insufficient, and compares unfavourably with even that of the soldier, and that the arrangements for the service are bad, others as positively affirm that there is no cause for complaint. The question is one that can be decided by scientific investigation alone; and on this point we believe that Dr. Ralfe, in his "Inquiry into the General Pathology of Scurvy," has very fairly represented the contrast between the sailors' and soldiers' rations, a representation which may be remembered with advantage in deciding the various points raised by the present controversy. Dr. Ralfe says, "The proportion of albuminates in both dietaries is about equal—perhaps, if anything, in favour of the soldier; for, though the sailor receives sixteen ounces of meat to twelve of the soldier, allowance must be made for the weight of salt and the nutritious matter dissolved out into the brine. But the sailor's dietary is below that of the soldier in actual quantity, and this deficiency is caused by the withdrawal of no less than twenty-four ounces of succulent vegetable food, which is poorly replaced by nine ounces of extra flour, five ounces of split peas, and an ounce and a half of currants and raisins. The presence of a considerable amount of chloride of sodium from the salted provisions renders the total weight of the ash higher in the sailor's rations than in the soldier's, otherwise the inorganic constituents are less — notably the potash, — whilst the alkalinity of the ash is considerably lower. This diminution of the alkalescence of the ash has no relation to the deficiency of potash, nor is it caused by the increase of the neutral salts, but is absolute, as can be shown by the fact that if sixteen ounces of fresh meat be given instead of sixteen ounces of salt, the alkalescence is only increased 0·2 grm., whilst the potash is increased 0·8 grm. Dr. Ralfe gives the alkalescence of the ash of the soldier's rations as rather more than half that of the alkalescence of the ash of the sailor's rations. To physiologists, who are aware of the importance of maintaining the normal alkalescence of the blood, and of the tissue changes that ensue when animals are fed on food whose ash is deficient in alkaline salts, as shown by the well-known experiments of Hoffman and Loscar, the above fact is significant, and to it may be attributed to a considerable extent the signs of premature age that are so often observed in sailors over forty years of age. No doubt, since the observations quoted from above were made in 1877, some improvements have been effected in the sailor's dietary, and he may now be able to purchase more luxuries out of his allowance, and, when his vessel is not cruising, procure fresh vegetables and meat in lieu of salted provisions; yet much remains to be effected. The arrangements, by which in the United States Navy, butter, tinned tomatoes, cranberries, pickles, and molasses are added to the rations, should be adopted in ours, and it should not be left to the option of the sailor to purchase these from the purser out of his savings. Again, the hours of the meal should be more in accordance with the men's requirements. The interval between supper at half-past four in the afternoon and breakfast at six the next morning is too long, although the defenders of the system declare the sailor is at liberty to save some of his dinner ration of biscuit and salt pork, and eat it cold for a late supper. We doubt if much would be left provided the sailor were in good health; whilst if the appetite were impaired, we do not think it would be tempted by cold salt pork and dry biscuit for supper. If the meal at half-past four were postponed to half-past six or seven, we believe it would be a great boon to the men, and would be beneficial to their digestion.

THE FALL OF THE YEAR.

THE boisterous winds which have lately prevailed remind us that we have been passing through the weather ordeal of the autumnal equinox. We notice and instinctively feel that the chilly wet of this period bodes nothing good to those who are exposed to its influence. All of disease that goes by the name of "cold" springs up as if in due season, and its wide prevalence even tempts the observer to seek for this commonest of ailments a cause, beyond climatic influences, in one or more of the numerous germ forms by which we are surrounded. Whether such will ever be precisely identified or not, the warning message of the time is one which none of us can afford to disregard. Careful and laborious investigations have shown that about this period the loss of weight which characterises the human body in the winter as compared with the summer months, and the oxidative changes with which it is associated, are wont to take place with especial suddenness. There is consequently a parallel depression of the vital powers, which must render them less able to resist the onset of illness. Whatever the state of the individual, the effect is more or less similar. It may not, indeed, be felt while the vigour of a robust constitution avails to turn aside the attacks of casual chill. It is otherwise with persons who from any cause lack this resistant faculty. Accordingly we find, as if by natural selection, the very young, the old or elderly, and the feeble of all ages—in a word, those of defective development or failing powers—reflect thus the influence of external cold. The danger suggests its own preventive. Into each detail of precaution or of cure we cannot now enter; but one or two

Digitized by Google

points are noteworthy. The avoidance of needless exposure is a mere axiom of common sense. The question as to what is appropriate clothing is a more important, though too often forgotten, consideration. In this connexion the value of light moderately thick woollen underwear, which at once conserves heat and allows free transpiration, can hardly be exaggerated. It should also be remembered that however judicious the precautions used, cold will still extort its tax of comfort, health, and life, and therefore that its earliest beginnings, especially in the more susceptible cases we have mentioned, are to be treated seriously. Neglect or mismanagement at this stage has often magnified a trifle of illness into a fatal catastrophe.

HOUSE REFUSE AND TOWN IMPURITIES.

A PAMPHLET on the above-named subject, by Mr. Alexander Bobrownicki, takes its various illustrations from the city of Manchester. The author aims at attaining for populations the highest procurable cleanliness of soil, air, and water, and he contends that an unhealthy town has no other meaning than a proportionate accumulation of decaying or putrescible matter. The causes of the present mischief, as exemplified in Manchester, are overcrowded dwellings badly kept; surface impurities in streets, yards, and corners; sewers of such construction as admits of their structure becoming sodden, and of their charging the surrounding subsoil with filth; with a resulting contamination of the atmosphere above by reason of the exit of foul air through the multiple ventilators inserted in the hope of abating the evils below. The author regards the natural duty of sewers to be "to protect the subsoil against contamination from the surface, and to maintain as steadily as possible the level of the subsoil water"; and he is a strong upholder of the Manchester pail system, which, whilst presenting certain remediable defects, gets rid annually of no less than 241,215 tons of material that might otherwise add to the pollution of soil and air. He also classes as amongst the dangerous impurities of a town the ordinary domestic smoke, and refers to certain experiments which give him hope that the vast and almost abandoned problem of purifying smoke may be practically and usefully resolved.

LEAD POISONING BY POTABLE WATER.

THE prominence given during recent years to the danger which attaches to some of our moorland water-supplies, owing to their action on lead during the passage of the water through lead service pipes, is referred to in a report by Dr. A. Swann, medical officer of health to the borough of Batley, Yorks. The Batley water, like that of other northern towns where lead poisoning has been somewhat rife, is derived from moorland, and it is stated that lead poisoning has been by no means unfrequent amongst the consumers of the public supply, and also that it has ceased on the substitution of iron for leaden service pipes. But whilst there have been a number of cases sufficiently severe to call for attention, Dr. Swann is convinced that there are many more in which mischief which is not so obvious is the result of the same cause; and that whilst a few people get "wrist drop" or other evident sign of the action of lead on the system, many other symptoms of disease, notably kidney troubles and degeneration of the bloodvessels, are being induced from the same cause. He refers also to the circumstance that the danger of lead poisoning is increased where any appreciable amount of organic material is present in the water. Such a condition might to some extent account for the varying effect of a water which is at one time apparently innocuous, at another liable to produce plumbism; and it calls for investigation in connexion with the suggestion made by Mr. W. H. Power, in the Annual Report of the Medical Officer of the Local Government Board for 1887, to the effect that some of the phenomena observed in occurrences of plumbism would, if observed in the biological laboratory in relation with the life processes of one or another microphyte, not be difficult of comprehension. And Mr. Power further suggests that the inscrutable behaviour of some of the moorland waters in this respect may be related to the agency, direct or indirect, of low forms of organic life. Dr. Swann goes on to state that he has learnt, through the librarian of the Société Française d'Hygiène, that no fewer than 907 of the leading physicians and surgeons of France have signed a petition to the Paris Municipal Council praying for the "absolute forbidding of the use of lead piping for the supply of water for dietetic and drinking purposes." Evidently the subject has been under consideration by the Society referred to, and the constantly recurring instances of lead poisoning by potable water which have of recent years been heard of in and about Yorkshire, call for some exhaustive investigation of the subject in our country also. The biological aspect of the question seems especially to call for skilled inquiry and research.

VACCINATION IN ITALY.

ROME now possesses a State Vaccination Office, and its medical director, Professor Ottavio Leoni, has just issued his first report on its operations. Small-pox, it seems, has been causing the death of from 15,000 to 20,000 Italians every year—a terrible life-tax, due, in the first place, to vaccination being non-compulsory, and, in the second, to the very inferior, often adulterated, lymph employed on occasion. Appeals to the public to have themselves vaccinated or revaccinated, even when responded to, were rarely effective, because no attention was paid to the quality of the lymph imported either from the national or foreign vaccigenous institutions. The Government, accordingly, empowered a commissioner to make a tour of inquiry among the chief European States, notably those in which small-pox had been virtually stamped out, to ascertain by what means an unadulterated and sufficient supply of lymph could be obtained, and to report on the system which seemed best adapted to compass this end. The result of this Commission is now seen in the State Vaccination Office of Rome, where all the methods most approved by science and experience for the preparation and conservation of lymph have been in working since the commencement of the year. The success of this office has exceeded the most sanguine expectations of its promoters. Within nine months, Professor Leoni tells us, there has been despatched from it to the communes, and even directly to medical practitioners, a quantity of vaccine lymph ample enough to inoculate more than one million of individuals. For first vaccinations the results have been "costantemente favorevoli" (constantly favourable), and for revaccinations they have been successful, on an average, in eighty-four per cent. of cases. No pains, says Professor Leoni, have been considered too minute or too laborious to secure the absolute purity of the lymph or to remove the risk of conveying through its means the germs of any malady transmissible from animals to man. In fact, before inoculating the calves they are kept for days under surveillance, to ensure their being in perfect health. As soon as the lymph is collected, these calves are killed and their carcases are subjected to a minute histo-pathological and bacteriological search to check the previous diagnosis of their soundness. If the slightest suspicion arises on this point, the lymph obtained from the suspected animal is destroyed. Through the Roman Vaccination Office there is placed at the disposal of every province of the peninsula an ample quantity of the vaccine so guaranteed, and we are informed that the Minister of War will shortly serve out to the army the lymph necessary for the revaccination of recruits,

Digitized by Google

greatly diminishing the expense hitherto incurred by each regiment for this purpose, and fraught with results superior to those obtained in the best of recent years. Compulsory vaccination, now *un fait accompli* in Italy, has crowned its efficiency by the means just taken to ensure the purity and due quantity of the vaccine, thus giving a deathblow to the nefarious traffic of the speculator in adulterated lymph, while removing the last obstacle to Italy's assuming her place among the sister Powers as a hygienically safeguarded kingdom.

THE REGULATION OF SLEEP.

INSOMNIA is rightly regarded as one of the marks of an overwrought or worried nervous system, and conversely we may take it that sound sleep lasting for a reasonable period, say, from six to nine hours in the case of adults, is a fair test of nervous competence. Various accidental causes may temporarily interfere with sleep in the healthy; but still the rule holds good, and a normal brain reveals its condition by obedience to this daily rhythmic variation. Custom can do much to contract one's natural term of sleep, a fact of which we are constantly reminded in these days of high pressure; but the process is too artificial to be freely employed. Laborious days with scanty intervals of rest go far to secure all the needful conditions of insomnia. In allotting hours of sleep it is impossible to adopt any maxim or uniform custom. The due allowance varies with the individual. Age, constitution, sex, fatigue, exercise, each has its share of influence. Young persons and hard workers naturally need and should have more sleep than those who neither grow nor labour. Women have by common consent been assigned a longer period of rest than men, and this arrangement, in the event of their doing hard work, is in strict accord with their generally lighter physical construction and recurrent infirmities. Absolute rule there is none, and it is of little moment to fix an exact average allowance provided the recurrence of sleep be regular and its amount sufficient for the needs of a given person, so that fatigue does not result in such nerve prostration and irritability as render healthy rest impossible.

NERVE EXHAUSTION AND OPIUM.

THE revelations following the death of Mr. Wilkie Collins may perhaps tend to increase the pernicious opium habit amongst those who are or who believe themselves to be in need of some extra comfort or support. The accounts given by Mr. Edmund Yates and by Mr. Hall Caine differ in some respects, although they agree as to the relatively large amount of laudanum habitually taken by the deceased *littérateur*. The former speaks of Collins as a martyr to nerves and gout, and seems to infer that the drug was resorted to for the relief of pain. The latter, in an elaborate report of a conversation held early in 1888, professes to give the novelist's apologetic explanation for his practice. He took laudanum "to stimulate the brain and steady the nerves," and he had been in the habit of taking a wineglassful of laudanum many times a day for fully twenty years. Few things are more lamentable than the obvious cost at which much literary work has been accomplished. De Quincey, Coleridge, Bulwer Lytton, and Wilkie Collins stand out as warnings against the folly of over-taxation of mental powers, and as examples of the habitual indulgence in opium. Rosetti, with chloral hydrate, and more recently the actor Damala, with morphine and cocaine, show the same form of weakness in resorting to other remedial (!) measures. It would be invidious to attempt to enumerate well-known names in literary and artistic circles of men whose work has been carried on beyond reasonable limits under the influence of alcohol. The lesson to be learnt is that brain power has its limitations as much as muscular power. Overwork produces exhaustion in both cases. Physiological laws cannot be set at defiance. So far as opium is concerned, it undoubtedly diminishes the susceptibility to external stimuli, and hence may enable a man whose attention is diverted by pain to obtain relief, and perhaps to concentrate his thoughts more fully upon some particular point; but, as a mental "stimulant," its employment is to be deprecated as unsound and dangerous. The constant need engendered by its use does not strengthen the position of a "stimulant," so often erroneously claimed for this drug.

RAILWAY ACCIDENTS IN 1889.

THE tale of fatalities on British railways has been unusually heavy during the first half of 1889, but the causes to which accidents are referred by the inspectors are very much what we have long been familiar with; except indeed that we note with satisfaction the absence from the present report of those frequent references to overwork as a probable cause of the unfitness for duty of peccant officials. It is true that the report is on this occasion a short one, and deals with comparatively few cases, so that perhaps not much can be deduced from the fact here noted. Otherwise one would be glad to think that the pressure of public opinion is making itself felt, and that railway managers are beginning to grapple with the problem of apportioning the work of railway men in such a way as to give them reasonable facilities of rest. In one or two passages the present report awakens a somewhat curious feeling of surprise and testifies afresh to what has often been indicated before—namely, the stultification of good rules by lack of consistency in the regulations, or the acquiescence of responsible officers in the habitual disregard of standing instructions by their subordinates. The following is a striking case in point:—Referring to an accident at the Keith station of the Highland Railway, Major Marindin says: "The evidence of the station-master shows that Rule No. 86 is not properly attended to at this station, for it is clearly not the practice to hold the facing points for outgoing Buckie trains, and it is needless to remark that if the pointsman had been at the points the collision could hardly have occurred. It is worse than useless to issue rules and then allow them to be habitually disregarded, and if it be true, as the evidence would seem to indicate, that the pointsman has sometimes other duties to perform, which prevent him from holding the facing points in accordance with the rule on that head, it would seem to be necessary that the staff should be increased."

THE INDECENT ADVERTISEMENTS ACT.

A MAN described as "shabbily dressed" was charged at the Westminster Police-court last week with distributing bills of an improper character—the said bills being a quack doctor's advertisement. Under the Indecent Advertisements Act, which comes into force on Jan. 1st next, this offence will be punishable by a fine or imprisonment. Under the circumstances the magistrate had no alternative but to discharge the prisoner. It may be well to point out that the Act in question is of a most stringent character, and appears to leave no loophole for evading its provisions. It enacts that "any person who affixes to or inscribes on any house, building, wall, hoarding, gate, fence, pillar, post, board, tree, or any other thing whatsoever, so as to be visible to a person being in or passing along any street, public highway, or footpath, or whoever affixes to or inscribes on any public urinal, or delivers or attempts to deliver, or exhibits to any inhabitant or to any person being in or passing along any street, public highway, or

Digitized by Google

footpath, or throws down the area of any house, or exhibits to public view in the window of any house or shop any picture or printed or written matter which is of an indecent or obscene nature," is liable on summary conviction to a penalty not exceeding forty shillings, or to imprisonment for any term not exceeding one month, with or without hard labour. It is gratifying to note that heavier penalties are provided for those who send or employ others to commit the acts enumerated, and also that certain advertisements of a notorious character relating to nervous debility and kindred disorders are, under the Act, deemed to be of an indecent nature. We may, therefore, hope soon to see our streets rid of this pest.

THE HUNTLEY JUBILEE COTTAGE HOSPITAL.

THE opening of a bazaar in aid of the funds of the Jubilee Cottage Hospital at Huntley by His Grace the Duke of Richmond and Gordon seems to have been a most auspicious event. His Grace has been in hearty sympathy with the movement from the beginning, and spoke words of cheer to the ladies and all other promoters in opening the bazaar. Dr. Farquharson opened the bazaar on the second day, and gave his strong opinion in support of such hospitals generally and this one in particular. The building is of granite, costing about £1257. It will contain sixteen or eighteen beds, and is replete with every convenience. Other outlay on grounds, walls, furnishing, &c., will bring the cost up to £1600. The sum of £853 was raised by the bazaar, and it is hoped to invest about £1200 as the beginning of an endowment for the working of the hospital. The Rev. Mr. Burnet, who has been a very active member of the working committee, in moving a vote of thanks to the Duke of Richmond, spoke strongly of the continuous encouragement he had given to the work from the beginning. We congratulate the poor of Huntley on having so valuable an institution provided for them. The hospital will be opened in November.

VISITING DAYS AT THE HOSPITALS.

OUR contemporary, the *Morning Post*, draws the attention of the authorities of one of our general hospitals to the sufferings undergone by those friends of the in-patients who arrive before the time for their admission to the wards. "They are obliged to stand about in the open air in front of the door and on the steps," and are thus exposed to rain and cold winds, with the risks which must follow such exposure. The hospital alluded to is, however, not the only one where indifference is manifested to the comfort of the visitors of the patients, and it would be well if the authorities of some of our other hospitals could see their way to provide shelter for the poor people who, in their anxiety to see as much as possible of their sick friends, arrive before the doors are opened.

THE TREATMENT OF ENDOMETRITIS.

DR. BOCK, assistant physician to the Hôpital St. Pierre, in Brussels, gives in *La Clinique* some notes of a series of cases of endometritis in which very satisfactory results were obtained by the use of Canquoin's paste applied to the interior of the uterus. Dr. Bock does not give the strength of the preparation, and this is not always the same in various continental formularies. The paste is made by mixing one part of chloride of zinc with two parts, or according to some formularies with one part, of flour, and enough water to enable the mass to be kneaded into the required form. For the uterus, of course, the form required was that of a stick of such a length as to reach from the fundus to the external os. A careful measurement had, necessarily, to be previously taken with the sound, and the cavity washed out with a sublimate solution. The stick of Canquoin's paste was then introduced and retained by means of a plug of cotton wool. For three or four hours the patients sometimes suffered a certain amount of pain, but this was by no means unbearable, and frequently there was no pain at all. Vomiting was occasionally produced in very sensitive subjects, but in none of the fourteen cases in which this treatment was adopted was there any pyrexia or other complication. The patients were kept in bed for a few days, and warm antiseptic injections given. The caustic produced a slough to the depth of from two to five millimetres, which came away, sometimes revealing a perfect cast of the interior, and even showing the commencement of the Fallopian tubes. Dr. Bock considers that this treatment is suitable—where the cervical canal is sufficiently patent—in all cases of chronic simple endometritis, as well as in fungoid or hæmorrhagic cases, and that it is peculiarly beneficial in cases of gonorrhœal origin, and he does not find that chronic or subacute inflammation of the uterine appendages forms any contra-indication. His results agree with those of MM. Polaillon and Dumontpallier, who first recommended this treatment, and who were successful in thirty-eight out of forty cases in which they employed it.

THE CHOLERA EPIDEMIC IN MESOPOTAMIA.

THE spread of cholera in Mesopotamia—a daily average of 200 fatal cases having, it is stated, taken place within the last week or two—is causing much anxiety at Constantinople, and fresh efforts are being made by means of sanitary cordons and the like to prevent the extension of the disease both into Palestine and further into Persia. The places most affected are towns and villages on the Euphrates and the Tigris from the Persian Gulf to a distance of several hundred miles inland; Bagdad being still a centre of the disease. The towns and ports hitherto affected on the eastern and western coasts of the Persian Gulf have been largely depopulated by flight, and there has in consequence been a corresponding diminution in the number of fresh cholera attacks.

CESSPOOLS AT BEXLEY HEATH.

A CORRESPONDENT directs our attention to the condition of Bexley Heath, which, for want of any better method, is entirely dependent on the use of cesspools. Many of the houses, he says, have several, and, the ground being porous, the inhabitants are not at the trouble to empty them. Lately, we learn, several deaths have occurred from typhoid fever, and yet so much apathy prevails that no public feeling is created in favour of a system of drainage. In times of heavy rains the cesspools overflow and the streams from which cows drink become polluted. We commend the remarks of our correspondent to the attention of the Local Government Board, in the hope that some step may be taken to rouse the inhabitants to a sense of their danger.

ELASTIC TISSUE.

DR. GALIN has made some experiments in the laboratory of Professor W. W. Podvysotski, in Kieff, on elastic fibres which led him to the conclusion that the elastic tissue can be saturated by a foreign substance circulating in the blood and tissues. This occurs not only when the whole system is saturated with the substance and the organs of excretion are inactive, but also when such saturation does not take place and the kidneys are acting normally. These experiments, as well as those of Blashko, throw a new light on the physiological importance of the elastic tissue, and suggest that it serves as a kind of depôt for the storage of septic and foreign substances, especially when their free excretion—by the kidneys, for instance—is in any way disturbed.

BREAD MANUFACTURE.

THE promoters of the Bread Union for London are putting forward as one of the benefits which will accrue to the public from the execution of their project the general introduction of cleanly methods of manufacturing bread. It cannot be denied that this is of itself a highly desirable object, for it is much to be feared that of the bread which is consumed in the metropolis a very seriously large proportion has been contaminated by unwholesome surroundings in the making. Although we do not understand how a baker's syndicate is going to accomplish or even to advance improved cleanliness in the manufacture of bread, we gladly bear testimony to the importance of wholesome and scientific methods of bread-making from the point of view of the public health.

FOREIGN UNIVERSITY INTELLIGENCE.

Geneva.—Dr. Vincent has been appointed Professor of Hygiene in place of Dr. Dunant, who has resigned.

Genoa.—Dr. Morselli, Extraordinary Professor in Turin has been appointed Professor of Mental Psychology.

Graz.—*Privat-docent* Dr. Escherich of Munich has been nominated to the Professorship of Pediatrics at Graz, rendered vacant by the transference of Professor von Jaksch to Prague.

Jena.—Professor Knorr of Würzburg has been appointed Professor of Chemistry and Director of the Chemical Laboratory in succession to the late Professor Greuther. Dr. Auerbach of Breslau has been appointed to the newly established chair of Physics.

Lausanne.—Dr. Stilling has been appointed Professor of Pathological Anatomy.

Moscow.—Dr. Schênoff has qualified as *privat-docent* in Physiology.

Munich.—Dr. Haug has qualified as *privat-docent* in Surgery.

Rome.—A new School for Experimental Hygiene has just been opened, and is intended to offer instruction not only to medical men, but to engineers, veterinarians, chemists, and pharmacists.

Vienna.—A new hospital has just been opened in the Tenth district of the city. It will now accommodate 200 patients, and when finished will have beds for 500. Dr. P. Pacher has been appointed Director.

Warsaw.—Dr. Kowalkowski has been appointed to the chair of Hygiene.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.

THE deaths of the following eminent foreign medical men are announced:—Dr. Duboué of Pau; Don R. Barberá y Blay of Zaragossa.—Dr. Maurice Longuet of Bourges, a rising provincial physician. He was the author, in conjunction with Dr. Ledentu, of the article "Lymphatique" in Jaccoud's Dictionary of Medicine.

SIR HENRY ROSCOE, M.P., delivered an address at Birmingham this week as president of the Midland Institute, taking for his subject "The Life-work of M. Pasteur," whose discoveries, he said, had culminated in the cure of that most dreaded and fearful of all maladies—hydrophobia. This was not the result of a happy chance, but the last link in a long chain of discoveries, including the exterminating of cholera, of cattle disease, and of splenic fever. Thus to M. Pasteur we owed the science of bacteriology, which dealt with the minute organisms called microbes, and which bids fair to revolutionise the theory and practice of medicine.

WE regret to have to record the sudden death of Mr. Thomas G. Hewlett, C.I.E., Deputy Surgeon-General, Bombay Army. Mr. Hewlett was waiting for a train at Finchley-road Station on the Metropolitan Railway when he suddenly fell forward on the platform and expired before medical assistance could be obtained. The deceased served in the Indian Mutiny campaign, and was Sanitary Commissioner for the Bombay Presidency until his retirement last year. He was fifty-seven years of age.

PROFESSOR JOHN WOOD, F.R.S., has resigned his chair of Clinical Surgery at King's College and the senior surgeoncy at King's College Hospital. Mr. Wood was first appointed Demonstrator of Anatomy in King's College in 1851, and assistant surgeon to King's College Hospital in 1856.

THE annual meeting of Fellows and Members of the Royal College of Surgeons to receive the annual report of the Council will be held on Thursday, Nov. 7th, at 3 P.M.

DR. VERGA, Senator of the Italian Kingdom, and well known as one of the leading alienists of Italy, is, we regret to hear, lying dangerously ill at Milan.

PROFESSOR EBERTH has succeedeed Professor Weigert as co-editor of the *Fortschritte der Medicin* (founded by the late C. Friedländer) with Dr. Unverricht.

THE FOUL BLACKWATER RIVER IN THE FARNHAM DISTRICT AND ITS DEADLY WORK.

BY ALFRED HAVILAND, M.R.C.S.E., L.A.C.,
LATE LECTURER AT ST. THOMAS'S HOSPITAL ON "THE GEOGRAPHICAL DISTRIBUTION OF DISEASE."

ON Thursday, Sept. 19th, I visited Aldershot, its camp, and the valley of the Blackwater River, with the view of gathering fresh information on the subject of my lecture at the Sanitary Institute in April last: "The Bagshot Sands and their Relation to Health." During this visit I met with two facts: (1) the frightfully polluted condition of the Blackwater River, which rises to the south of Aldershot near Hungry-hill, and skirts the whole of the subdistricts of Frimley and Farnborough as far as their northern boundaries; the parishes of Aldershot and its military camps, Ash and Normandy, and lastly, Frimley and Farnborough, being immediately within range of its pestilential local climate; and (2) diarrhœa of a severe form prevailing in the parish of Frimley. As usual, too, I found the inhabitants loud in their complaints of the filthy state of their river and of the incapacity of the Farnham sanitary authority to deal with the source of their troubles. Since then I have informed myself of the history of the preventable deaths that have occurred during the last ten years and a half in this plague-stricken valley. I shall, however, confine myself to the two great causes of death, diphtheria and diarrhœa, for after a long and wide experience I have, with others of equal or greater experience, come to the conclusion that their causes are sewage-begotten and air-borne. The population of the above parishes and military station amounted in 1881 to 26,097 persons, amongst whom there occurred during the ten years and a half from the 1st January, 1879, to the 30th June, 1889, 197 deaths from diphtheria and 208 deaths from diarrhœa. Omitting, however, the six deaths from diphtheria and the two from diarrhœa, which have occurred this year, the numbers will be 191 and 206 respectively for the ten years 1879–1888, which amount to an annual death-rate to every 10,000 persons living of 7·31 for diphtheria and 7·89 for diarrhœa. But 190 of the 191 deaths from diphtheria occurred during the six years

Digitized by Google

1883–1888, so that the annual mortality from diphtheria alone equalled 12·13 deaths to every 10,000 persons living, when it should have been *nil*. On the other hand, in the subdistrict of Farnham, including the parishes of Farnham, Waverley, Frensham, and Dockenfield, the population amounted in 1881 to 13,386 persons, who are out of the influence of the baneful Blackwater and on the southern slope of the water parting. During the ten years 1879–1888, the number of deaths registered in this subdistrict were from diphtheria 64, and diarrhœa 66, which would be equal to an annual death-rate to every 10,000 persons living of 4·78 and 4·93 respectively.

The Blackwater divides the parish of Aldershot with the South Camp and the parish of Farnborough with the North Camp from that of Frimley, the first two being on the left and the last on the right bank. We have seen what has taken place on the Frimley side; let us now see what has obtained in its opposite neighbour, Farnborough. Out of the 19 deaths from diphtheria that were registered in the Farnborough subdistrict, scattered over the North Camp at Aldershot, the parishes of Cove, Hawley with Minley, Yateley, and Farnborough, eight occurred in the small parish of Farnborough during the two years 1885 and 1886, amongst a population of only 3426 persons, giving a death-rate from this cause equal to 11·67. At the time this was occurring on the left bank of the foul river there occurred 56 deaths in the subdistrict of Frimley, 22 of which took place in the small parish of Frimley, amidst a population of only 4012, or at an annual death-rate of 27·41 to every 10,000 living. Such an experience ought to have acted as a motive for immediate action towards the extirpation for ever of the wretched cause of so much disease and death. The two facts I commenced with stare us in the face; and there are other evils impending, for the district registrar had, up to the end of June, already registered 6 cases of diphtheria in the subdistrict of Frimley and 2 in that of Farnham.

The history of the last ten years points to the fact that diphtheria was first fatal in the parish of Farnham, around the source of the Blackwater, during 1879–82, when 6 deaths occurred; up to the last date only one death had occurred in the Frimley subdistrict. In 1883, 12 deaths took place; in 1884, 66; in 1885, 56; in 1886, 25; in 1887, 9; in 1888, 22; and in the first two quarters of this year, 6 deaths. Dr. John A. Lorimer, the medical officer of health, mentions in his report for 1888 that "in York Town and Camberley there were 51 cases of diphtheria reported, 17 of which proved fatal; one in three." In the Frimley subdistrict the fourth or winter quarter is the most fatal; in the Farnham subdistrict the second quarter. Diarrhœa in both subdistricts is most fatal in the third quarter. Both diphtheria and diarrhœa can be clearly traced down the stream, their causes acquiring strength as they go. The river is in a valley of the middle Bagshot sands, characterised by a retentive and peaty soil, and is sheltered on the N.E. and S.W. by the Chobham ridges of the upper Bagshot sand on the right bank, and heights of a similar geological character on the left; the consequence is that free air flushing by the prevailing winds is hindered; and the pestiferous emanations from its foul water and still fouler banks lie about, and overflow into the houses which skirt the valley, like those of Farnborough, Frimley, York Town, Camberley, &c., where they meet with other emanations, the outcome of defective local drainage and an insufficient water-supply. The remedy is simple—as a watercourse the river should be protected according to the law. There is plenty of hungry land on the heights where the sewage would do good. The Upper and Lower Bagshot sands, as I have fully shown in the paper referred to, are eminently conducive to health; but their power for good may be easily destroyed when the springs that arise in them and the rivers that flow through their valleys are polluted. The Aldershot camps are much too near such a foul source of death; and the deaths from diphtheria that have already occurred in the town and the camps should long ago have made it imperative upon the Farnham rural sanitary authority to stop the evil at the fountain-head. In conclusion, I must add that the medical officer of health (Dr. Lorimer) has year after year brought the state of the Blackwater, the defective drainage, the insufficient water-supply, and the deplorable sickness and mortality caused by diphtheria and other preventable diseases, before the Farnham Sanitary Authority, but without the slightest effect. It would be useless for the Hartley Wintney Authority to take the initiative, whilst the pollution comes from above them. All the sanitary authorities should combine towards one end, the removal of the present and the prevention of future nuisance.

Pharmacology and Therapeutics.

SCHUHKRAFFT'S CRYSTALLISED PERUVIAN BARK (OR SOLUBLE QUINQUINA).

MESSRS. BURGOYNE, BURBIDGES & Co., of Coleman-street, have forwarded to us a specimen of the above. It is a preparation intended to obviate the unpleasant grittiness occasionally complained of when cinchona bark is employed. It is guaranteed to contain exactly its weight of the purest bark imported from Bolivia, and thus to be of definite composition. The samples submitted to us dissolve readily in water, and also in any form of wine, giving a solution of agreeable colour and characteristic taste and odour, entirely free from any perceptible traces of woody fibre. The "soluble quinquina" is also prepared in an "effervescent" form, intended to yield a pleasant, acidulated, effervescing saline draught for summer use. In our hands this preparation has not yielded very satisfactory results; the effervescence has been very slight, and the compound has only dissolved slowly. The former preparation, however, will probably find favour with the profession and the public, since the advantages of cinchona bark can be obtained from it without the troublesome necessity of shaking the mixture.

COMPOUND SULPHUR LOZENGES.

These lozenges, prepared by R. Hogg & Son, of Southwick-street, have an agreeable, slightly saccharine taste. They are quite free from grittiness. They form a convenient method of obtaining the general alterative and laxative effects of sulphur.

YELLOW OXIDE OF MERCURY SUBCUTANEOUSLY ADMINISTERED.

Dr. Chernoguboff has made a number of observations in the Miasnitski Hospital in Moscow in regard to the subcutaneous injections of the yellow oxide of mercury in connexion with the treatment of syphilis, and has come to the following conclusions. Two-grain doses cause a quicker disappearance of all symptoms than smaller doses, reducing in 92 per cent. of cases the necessity for professional visits to one or two. In fresh cases an interval of ten or eleven days between the injections is sufficient to prevent salivation, but old cases require a longer interval. The injection should be made into the cellular tissue, and not into the muscles, to avoid the great pain in the case of the latter, and the frequent occurrence of abscesses. The treatment is said to cut short all symptoms, both when the disease is progressing and when it is on the decline; new spots, especially on the mucous membrane, are very rare. In tertiary syphilis, according to Dr. Chernoguboff, early gummata, and those which are breaking down, quickly disappear under the treatment; but in impetigo and rupia iodide of potassium is often required in addition. Local applications do not usually accelerate a cure, except in sore-throat with papular infiltration of the tonsils, which requires heroic treatment. Relapse occurs as in other methods after two or four months. Men and women equally bear well large doses; children from twelve to fourteen years require one grain only. The treatment is contraindicated in severe anæmia which has not been caused by the specific disease, in general exhaustion, undoubted alcoholism, chronic inflammation of parenchymatous organs, and in extensive dental caries; pregnancy is not a contra-indication. Mercury is found in the urine in from four to eight hours after the injection.

A NEW FEVER HOSPITAL AT BOLTON.—On the 2nd inst., Mr. John Wardle, the chairman of the Bolton Rural Sanitary Authority, laid the corner stone of this new fever hospital, which will be erected on the pavilion plan. Hospital accommodation for the isolation of infectious patients has been a long-felt want in this extensive district.

TENTH INTERNATIONAL MEDICAL CONGRESS, BERLIN, 1890.

THE preliminary steps for the promotion of the forthcoming International Medical Congress were taken on Sept. 17th, when a meeting of delegates was held at Heidelberg, and the organisation as concerns the general arrangements, sections, &c. was framed. It was decided that the Congress should open at Berlin on Aug. 4th and close on Aug. 10th. The organising committee was constituted by Profs. Virchow, von Bergmann, Leyden, and Waldeyer, and Dr. Lassar was appointed general secretary. This committee was empowered to nominate honorary presidents and secretaries; and for each of the several sections a committee was formed consisting of nine associates, whose duty it should be to prepare the work of the sections, each committee having upon it one member residing at Berlin (acting as its chairman) to facilitate the transaction of the business (see appended list, the name of the member thus selected being indicated by an asterisk). It was also decided to hold an international medical and scientific exhibition in connexion with the Congress. The regulations of the Congress as to the admission of members &c. and the general programme were also adopted. There are to be eighteen sections (*vide* below), and besides the sectional meetings there will be general meetings for the transaction of the business of the Congress, for addresses and reports of general interest. The official languages will be German, English, and French, and the programmes and regulations will be printed in all three languages. Communications regarding the work of the sections are to be addressed to the chairmen of the sections, and all other communications to the general secretary, Dr. Lassar, Berlin, N.W. Karlstrasse, 19.

The following is a list of the provisional councils of the various sections:—1. *Anatomy:* Flemming (Kiel), Gegenbaur (Heidelberg), Hasse (Breslau), *Hertwig (Berlin), His (Leipzig), v. Kolliker (Würzburg), Kupffer (Munich), Merkel (Göttingen), Schwalbe (Strasburg). 2. *Physiology and Physiological Chemistry:* *Du Bois-Reymond (Berlin), Heidenhain (Breslau), Hensen (Kiel), Hüfner (Tübingen), Hoppe-Seyler (Strasburg), Kühne (Heidelberg), Ludwig (Leipzig), Pflüger (Bonn), Voit (Munich). 3. *General Pathology and Pathological Anatomy:* Arnold (Heidelberg), Bollinger (Munich), Grawitz (Greifswald), Heller (Kiel), Ponfick (Breslau), v. Recklinghausen (Strasburg), *Virchow (Berlin), Weigert (Frankfort a. M.), Zenker (Erlangen). 4. *Pharmacology:* Binz (Bonn), Böhm (Leipzig), Filehne (Breslau), Jaffé (Konigsberg), *Liebreich (Berlin), Marmé (Göttingen), Penzoldt (Göttingen), Schmiedeberg (Strasburg), Hugo Schulz (Greifswald). 5. *Medicine:* Biermer (Breslau), Gerhard (Berlin), Kussmaul (Heidelberg), Leube (Würzburg), Leyden (Berlin), Liebermeister (Tübingen), Mosler (Greifswald), Naunyn (Strasburg), v. Ziemssen (Munich). 6. *Diseases of Children:* *Henoch (Berlin), Heubner (Leipzig), Kohts (Strasburg), Krabler (Greifswald), Ranke (Munich), Rehn (Frankfort a. M.), Soltmann (Breslau), Steffen (Stettin), Ungar (Bonn). 7. *Surgery:* Bardeleben (Berlin), *v. Bergmann (Berlin), Czerny (Heidelberg), König (Göttingen), v. Lotzbeck (Munich), Schede (Hamburg), Trendelenburg (Bonn), v. Volkmann (Halle), Wagner (Königshütte). 8. *Obstetrics and Gynæcology:* Fritsch (Breslau), Gusserow (Berlin), Hegar (Freiburg), Hofmeyer (Würzburg), Kaltenbach (Halle), Löhlein (Giessen), *Martin (Berlin), Ohlshausen (Berlin), Winckel (Munich). 9. *Neurology and Psychiatry:* Binswanger (Jena), Emminghaus (Freiburg), Erb (Heidelberg), Flechsig (Leipzig), Fürstner (Heidelberg), Grashey (Munich), Hitzig (Halle), Jolly (Strasburg), *Laehr (Berlin-Zehlendorf). 10. *Ophthalmology:* O. Becker (Heidelberg), Eversbusch (Erlangen), v. Hippel (Giessen), Hirschberg (Berlin), Leber (Göttingen), Michel (Würzburg), Schmidt-Rimpler (Marburg), *Schweigger (Berlin), v. Zehender (Rostock). 11. *Otology:* Bezold (Munich), Bürkner (Göttingen), Kirchner (Würzburg), Kuhn (Jena), *Lucae (Berlin), Magnus (Königsberg), Moos (Heidelberg), Schwarz (Halle), Trautmann (Berlin). 12. *Laryngology and Rhinology:* Beschorner (Dresden), *B. Fraenkel (Berlin), Gottstein (Breslau), A. Hartmann (Berlin), Jurasz (Heidelberg), H. Krause (Berlin), Michael (Hamburg), Schech (Munich), M. Schmidt (Frankfort a. M.). 13. *Dermatology and Syphilography:* Caspary (Königsberg), Doutrelepont (Bonn), Köbner (Berlin), *Lassar (Berlin), Lesser (Leipzig), Lewin (Berlin), Neisser (Breslau), Unna (Hamburg), Wolff (Strasburg). 14. *Diseases of the Teeth:* *Busch (Berlin), Calais (Hamburg), Hesse (Leipzig), Fricke (Kiel), Holländer (Halle), Miller (Berlin), Partsch (Breslau), Sauer (Berlin), Weil (Munich). 15. *Hygiene:* Flügge (Breslau), Gaffky (Marburg), Graf (Elberfeld), F. Hofmann (Leipzig), R. Koch (Berlin), *Pistor (Berlin), V. Pettenkofer (Munich), Wolffhügel (Göttingen), Uffelmann (Rostock). 16. *Medical Geography and Climatology* (History and Statistics): Brock (Berlin), Dettweiler (Falkenstein), Falkenstein (Lichterfelde), Finkelnburg (Bonn), Guttstadt (Berlin), *A. Hirsch (Berlin), Lent (Cologne), Wenzel (Berlin), Wernich (Coeslin). 17. *State Medicine:* Falk (Berlin), Günther (Dresden), V. Hölder (Stuttgart), Knauff (Heidelberg), Lesser (Breslau), *Liman (Berlin), Reubold (Würzburg), Schönfeld (Berlin), Skreczka (Berlin). 18. *Military Hygiene &c.:* Abel (Stettin), v. Coler (Berlin), v. Fichte (Stuttgart), Grasnick (Berlin), Grossheim (Berlin), *Krocker (Berlin), Mehlhausen (Berlin), Mohr (Munich), Roth (Dresden).

THE PARIS UNIVERSAL EXHIBITION.

(FROM OUR SPECIAL CORRESPONDENT.)

French Pharmaceutical and Chemical Exhibitions.

CLASS 45—that is, the section devoted to the exhibition of chemical and pharmaceutical products—is situated in the main building, about half-way between the English section and the machine gallery. It is a large exhibit, and not without interest even to those who know absolutely nothing about chemistry. The variety of colour and shape of the crystals is attractive, and by the uninitiated some of the crystals are mistaken for precious stones. The crystallisations of metallic bismuth, shown by Poulenc Frères, are, for instance, very striking. Close by them will be found a remarkable specimen, actually weighing 500 grms., of melted iridium, shown by Messrs. Billault of Billancourt, well-known manufacturers. Several great chemical works exhibit, notably the Société Ancienne de Produits Chimiques. M. Maletra, one of the oldest firms, which, together with that of Coignet and Co., are *hors concours* and members of the jury. We have the Société de Saint Gobain, who were the first to introduce into France the English method of making sulphur from soda residue. They now profess to supply sulphur of a purer quality than the Sicilian sulphur. The Pharmacie Mialhe of Puteaux is also a renowned house, and they exhibit nitrates, chlorhydrates, and synthetic cocaine. Messrs. Vée and Co of Ivry have a special method of congealing concentrated extracts by cold applied in dry vacuum. They exhibit specimens of such extracts, notably of bitter orange extracts, pine wood, tolu cherry, quinine, &c., also photographs of the apparatus they employ for this purpose. The Central Pharmacy of France, which boasts of a capital of £400,000, has a very notable exhibit, including some specimens of the alkaloids of quinine. Together with Messrs. Billault, they have received the grand prize.

In the centre of the section there is a very interesting collective exhibit of French pharmacists, giving the principal results of researches during the last century. There are books, illustrations, chemical apparatus, specimens of plants, and some of the special medicaments that enjoy the highest repute. Among these may be noted Aubergier's syrup of lactucarium. This sedative medicament was approved by the Academy of Medicine in 1862, and inscribed on the Codex. The lactucarium is obtained by incisions made in the stem of the Lactuca virosa altimassa, planted in the specially fertile soil of the Limagne of Auvergne, and is worth about £12 the kilogramme. This syrup of lettuce has a corrective effect on the small quantity of opium which it contains, and ensures results which that same quantity of opium taken alone would never give; hence its position among the useful medicaments of the century. Close at hand Messrs. Adrian and Co. of Paris have a varied and rich exhibition. They show, for instance, a jar of crystallised digitaline, which they estimate at £480, the drug being generally sold at 30 fr. the gramme. They have the whole series of digitalines, terpines,

Digitized by Google

and the soluble hæmoglobin with which the Vin Deschiens is made. They have obtained some exceptionally small crystals of iodide of potassium, which are consequently much easier to dissolve. Then they have subnitrate of bismuth eight to ten times lighter than what is generally made. This bismuth is consequently much easier to exhibit. Just opposite this stall is placed the absolutely scientific and non-commercial discoveries and exhibits of M. Tauret which have obtained the highest award, the grand prix. The next to notice is the well-known firm of H. Fournier and Co. Dr. Nogareaud courteously answered all questions relating to these exhibits. One of the most practical innovations is a large assortment of sugar-coated pills, with the composition of the pill printed in very clear, neat letters on the coat. Further, the sugar itself is of different colours, so that mistakes cannot arise, each pill having its distinct colour and bearing its own label. The coating is made with great care, so as to allow of exposure to tropical climates. This firm makes also Dr. Belloc's vegetable carbon—a charcoal powder obtained by the careful carbonisation of poplar tree wood, which, it appears, is preferable to other woods for therapeutic purposes. This firm has largely contributed to introduce guaiacol, which forms 60 to 90 per cent. of the component parts of creasote. The guaiacol they obtain is a colourless liquid, with an agreeable odour; it boils at 200° C., and its specific gravity is 1117 grammes. Where large quantities of creasote are indicated but cannot be supported by the patient, guaiacol may prove of service.

A number of specialties will be seen in this section, such as, for instance, the Capsules Thévenot of Dijon. Composed in part of gum, they are more soluble and more supple than ordinary capsules, and therefore facilitate the administration of larger doses of medicine. The Lin Boggio-Aulagne is a preparation of linseed meal for poultices, from which the fats that become rancid have been removed. Then there is the popular Papier Fayard et Blayn, a favourite in so many French houses, where it is used as a substitute for our poor man's plaster. The Pharmacie Le Beuf exhibits an English specialty—namely, coal tar preparations, lotions, and emulsions. The elixir of Boldo Verne, said to be useful in liver diseases, is presented to the public. The boldo is a plant found in Chili, and has been used considerably, among other authorities, by Professor Gubler. It has therefore its place in the Exhibition. Then there is the Edulcer sugar for diabetic patients, and numerous preparations by Le Perdriel and Co. These latter include fagoglycine, given instead of cod-liver oil, effervescing salts of lithia, &c., and some thapsia plasters, conveniently prepared for general use and travelling. Of course the Papier Rigollet is close at hand, as also the opposition portable mustard leaf, called Papier Moutarde, which has the advantage of being a little cheaper. The Cachet Limousin, the cigarettes Aspic for asthma, are familiar acquaintances; and, as something more novel, we have close by Ad. Langlebert's preparations of the convalilaria majalis. But, among these French preparations, there are one or two missing. For instance, the medicament of all others most pleasant to children, the Tamar Indien, is absent. An aperient which is as good as a bonbon from Boissier or Sirandin is so typical of French refinement and elegance in the little things of life that it certainly should have held a prominent place. Nor could I find Dr. Clin's bromide of camphor capsules, used in Dr. Charcot's clinique, and the Fer Rabuteau. This latter preparation is based on the theory propounded by the eminent French chemist, M. Wurtz, that the principal acid of the gastric juice is chlorhydric acid. By numerous experiments on animals, Dr. Rabuteau established that iron is converted by the stomach into proto-chloride of iron before its assimilation. Hence he sought to prepare an iron in the condition necessary for its assimilation by the system without having to tax the gastric juices for that purpose. The Fer Rabuteau is therefore a proto-chloride of iron, and is certainly one of the most popular ferruginous preparations known in France. M. Chaissaing has the gold medal for his scientific exhibits of pepsin. M. Chaissaing insists very forcibly on the necessity for the practitioner possessing a soluble pepsin of a known strength. The fibrin and albumen should not merely be dissolved, but they should be fully converted into peptones. A pepsin may dissolve a considerable amount of fibrin, but digest only a small quantity. The Vin Chaissaing is known throughout France, and its popularity will increase now that the Chaissaing pepsins have obtained the gold medal.

Just outside the section are some fine exhibits of quinine bark. C. Hoffmann's stall has a very complete collection of every possible variety. There is the trunk of a very large tree from Ceylon, big branches from Java, specimens of second-growth bark, and the cultivated Silvestre of Bolivia. These are the best quinines, whether cultivated or wild, and are used for the Quina Laroche and other well-known French productions. A shipload, by the way, of this preparation of quinine has been despatched to the unfortunate workers who, under the most unhealthy conditions, are trying to pierce the Panama Canal. The Quina Laroche is a mixture of the grey, yellow, and red quinines in a sweet southern wine of eleven to twelve degrees of alcohol, so combined that the bitter taste is almost imperceptible. The firm of Veuve Breton et Fils have also a very large exhibit of chinchonas, &c., and some cantharides. Such briefly are some of the points of interest to be noted in the French pharmaceutical section.

(To be continued.)

SHEFFIELD MEDICAL SCHOOL.

THE introductory address was given by Mr. Charles Atkin. After a few words of welcome to the students, the lecturer gave a brief epitome of the history of Anatomy and its allied science Surgery from the earliest times up to their establishment in Britain. The causes of the association of surgery and barbery were discussed up to their final dissolution of partnership in 1745. Note was made of the absence of allusions to anatomical knowledge in Holy Writ, and the paucity of reference to anything surgical, though sore eyes, roller bandages, and wine and oil dressing for wounds were mentioned. Very little of surgical interest was to be found in the writings of Chaucer or Sir Thomas More. Shakespeare's knowledge of surgery appears to have been limited to the primitive methods of stopping bleeding by cobwebs and flax with whites of eggs. Parmaceti is recommended for an inward bruise, as are plantain leaves for broken shins. Wounds are described as being treated by balsam, tents and caustics, and burns by applied heat. Broken bones when united are stated to be stronger than they were before. Mortifications and gatherings also receive mention. The only allusions to a distinct surgical operation on the *living* body, besides leeching and lancing, are in "Coriolanus," where this warrior is compared to a disease which must be cut away; and in "King Richard II.," where the Duke of York begs that the life of his son Aumerle may be cut off like a festered joint. Shakespeare was certainly conversant with the anatomy of the brain, notwithstanding ecclesiastical denunciations against opening the head as the seat of the soul. Samuel Butler lived in the days of legalised anatomy and the knowledge of the circulation of the blood, so "Hudibras" is replete with surgical allusions, such as "Well! Sidrophel, though 'tis in vain to tamper with your crazy brain without trepanning of your skull," &c., and "anatomists dissect and mangle to cut themselves out work to wrangle"; and, again, "can no transfusion of the blood that makes fools cattle do you good?" This last referred to the craze which had seized the public mind that rejuvenation—the true elixir vitæ—consisted in injecting fresh blood from animals into the veins. Though the necessity of a knowledge of anatomy to the surgeon was insisted upon in the second century, no further progress was made till the middle of the sixteenth. Galen likened a man working in or at a man's body without knowledge of anatomy to a blind man pruning a vine or carving an image and to an architect building without order or plan. And yet to-day, seventeen hundred years after, bonesetters who have never seen the interior of a joint continue to flourish amongst us. With regard to medical education, stress was laid on the value of preliminary training; carpentering for ensuring accuracy and acquiring manual dexterity was recommended, as well as a good foundation in physics, chemistry, and biology. The lecturer expressed the opinion that a higher standard for the preliminary examination was desirable, so that ne'er-do-weels could be weeded out from the first, thus saving much time, trouble, expense, and disappointment. Though a personal fondness for languages was expressed, the lecturer did not

Digitized by Google

recommend the study of them to be kept up except for the increasing of delights or for the chance of finishing medical education abroad; everything of value being immediately translated. The natural sciences, on the other hand, were strongly recommended. With regard to examinations, the lecturer made a difference between essentials and fundamental facts, on the one hand, and recondite details on the other, and he gave his opinion that only the latter should be prepared for. Stress was laid on the necessity of students acquiring an all-round knowledge in the specialties, as many of them might wish to practise in the colonies, where they would occasionally have to rely solely on their own resources. The subject of healthy homes was discussed, and not only was disease stated to be often the result of environment, but also drunkenness, immorality, and crime. With regard to hospitals, Mr. Atkin said there was no doubt but that more care might be displayed in checking the attendance of people who could well afford to pay a medical man a reasonable fee, though he considered the majority of hospitals would be acquitted of malversation. After accounting for the differences of medical opinion, and explaining the significance of the emblems of Æsculapius, the lecturer expressed a hope that the gentlemen present would learn to love their work, and that they would all become ornaments to the profession.

HOTELS.

(BY OUR ROVING CORRESPONDENT.)

THE subject of hotels is very important, because signs are not wanting that hotel living is on the increase and will continue to increase. There are many advantages in living in an hotel, and there can be no doubt that in a really well-managed establishment a very remarkable amount of ease and luxury can be obtained at a moderate cost.

In the remarks which follow, the hotels of cities are left out of consideration, and I propose to deal mainly with hotels erected at spots set aside as health resorts or recreation grounds, where those who are sick or jaded go for recovery and change.

It is a remarkable fact that by no means unfrequently the first idea which seizes on the mind of an hotel speculator or his architect is one which is essentially destructive. Having decided to "*exploiter*" this or that district by means of an hotel, he proceeds to erect a building which is absolutely out of harmony with its surroundings, and which tends to destroy, in so far as it be possible for one building to operate in that direction, those very characteristics which have made the locality famous or attractive. It is very difficult for the Cockney, be he architect or inn-keeper, to cast his slough, and the predominating idea in the narrow and self-sufficient minds of Cockneys (be they from London, Paris, Vienna, or New York) is the mere transplanting of a crude slice of a city even into a district which may be the embodiment of Nature in her wildest moods. Having perpetrated such an act, he probably speaks of it as the march of civilisation. Instances will readily occur to the mind of localities which hotel-keepers have done their best to spoil. Notable examples are to be found at Arcachon, where the brute mass of a huge hotel towers above the surrounding villas and pine-trees; at Meiringen and Thun, in Switzerland, where, alongside of rows of *châlets* and quaint mediæval towers, the barren-minded architects have placed buildings of which the best that can be said is that they might pass unnoticed in a fifth-rate Parisian boulevard; and at Augsburg, in Bavaria, where the "Drei Mohren," a hostelry associated with Charles V. and the Fuggers, has been pulled down and re-erected on the model of the "Langham." The first thing which the writer would impress upon hotel architects is to be careful to let the buildings harmonise with the locality. The hotel at which a traveller first alights on visiting a new district ought to serve as an introduction, as it were, and prepare his mind for the pleasures which may be in store for him.

The most common fault in hotels is the fact that the buildings are too high, and occupy an area which is absolutely inadequate for the purpose. In big cities this may be a necessity, but no such necessity exists in country places, and the main reason why country hotels are built on the model of town hotels is probably to be found in the very simple fact that, as I have hinted, most architects are Cockney-minded. The provision of adequate area for the inmates is insisted upon by designers of hospitals, prisons, and similar institutions, and perhaps some day the same wise ideas will prevail with designers of hotels, which are institutions in which the inmates are ready to pay handsomely to be made really comfortable and to be maintained wholesomely. In hospitals an acre of ground is considered desirable for each hundred patients; and, although this allowance may be excessive, it is well to bear in mind that when numbers are congregated under one roof it is absolutely necessary that area in proportion to the numbers be provided, and it is most important also to remember that even an excess of cubic space will not compensate for lack of area. Nearly all hotels stand upon a very deficient area; and almost all hotels when full present a degree of overcrowding which, from a sanitary point of view, is scandalous. Huge towering buildings, with as many floors as a warehouse, and perforated with staircases and hoists, so that each floor is "ventilated" into those above and below, may be tolerated for a short time by those who are hurriedly intent upon business or a whirl of "pleasure," but as places for prolonged sojourn or anything like permanent residence they are most undesirable. A resident in an hotel ought to be able to enjoy at pleasure either society or seclusion. In the public rooms he should find all that movement and gaiety which constitute the sole pabulum of dull minds, and which all of us enjoy at times. While in his own apartment, he ought to have quiet and peacefulness in the highest degree. This end cannot be attained without adequate area, and it is notorious that one of the greatest defects of modern hotels is the impossibility of being quiet until all the inmates are in bed and asleep. In an hotel where prompt service conduces so much to comfort, it is needless to say that the sources of supply should be equally accessible from all the living rooms. How to combine the possibility of seclusion with accessibility to the basis of supply is the problem for hotel architects to solve. It seems to me that the best general plan would be to place the living rooms in a quadrangle, having the common rooms in a distinct and loftier building in the centre, the kitchen being on the top floor of the central building, so that the smell of it would blow completely away. This smell of the kitchen is a terrible fact in most hotels, and it is certainly surprising to find how infinitely rarely do architects take any trouble even to minimise it. I can recall one hotel, and only one (at Royat in Auvergne), where the kitchen is placed on the top floor of the building; but I could name several in which the effluvia of the kitchen are conducted with infinite care into the bedroom corridors. The old-fashioned plan, which was common in England, of building inns round an open court and with open corridors was good, and the fact that the court was really open probably prevented unwholesome effluvia from reaching the bedrooms. In the present day it is common to find the rooms arranged, not round an open court, but around the well of a staircase which is closed, and instead of two tiers of rooms there are seven, eight, or even more. No worse design from the point of view of safety, comfort, or wholesomeness can well be conceived. With such a design there is no escape from noise or effluvia; there is a minimum amount of privacy, a maximum amount of labour in travelling from the front door to the rooms, and when these buildings catch fire we can only say, "God help those who live on the top floors!" And yet this is the commonest form of hotel, and the idea seems prevalent that the height of an hotel is nowadays immaterial, because the hydraulic lift abolishes (for the guests) the labour of going upstairs. That these lofty hotels enable proprietors to increase their accommodation without increase of ground-rent there is no doubt, but there is equally no doubt that from the guest's point of view they offer no advantages whatever, unless (which is very doubtful) they cheapen the cost of rooms. Of the hygienic disadvantages I have already spoken, and it remains only to be said that in order to check the drifting of effluvia and noise from floor to floor it is absolutely essential that staircases and lifts should be placed in buildings projecting from the main building and provided with independent ventilation. The time and labour which are involved by living at or near the top of a lofty building is self-evident. Theoretically, the lift reduces the expenditure of time and labour to a minimum, but practically the guest is often willing to

Digitized by Google

incur the labour of mounting by his own effort rather than lose time by waiting for the lift. Now the work done in raising the body vertically to a height is calculated to be equal to about twenty times the labour of walking on a level, so that the man who raises his body seventy feet in order to reach an upper floor of an hotel does an amount of work equal to walking 1400 feet on the level; so that, from the point of view of the labour incurred, it makes no difference to the guest whether his room be seventy feet vertically or 1400 feet horizontally from the front door of the hotel. These lofty buildings may, as I have said, be necessary in great towns, but it is clear that they offer so many physical and hygienic disadvantages as to render them quite indefensible in country places, where the price of land does not preclude the possibility of giving a reasonable area to a building intended for the accommodation of a large number of persons.

(To be continued.)

THE SANITARY INSTITUTE OF GREAT BRITAIN.

THE Session of this Institute was opened on Tuesday evening, the 8th inst., at the rooms of the Institute, Margaret-street, Sir Douglas Galton in the chair. Sir E. Chadwick read an address on "The General History and Principles of Sanitation," and commenced by referring to the earliest-known traces of sanitary science. The terrible scourging plagues that occurred amongst the Greeks, as at Athens, were evidences of low sanitary conditions; and there were then imperfect means for the collection and distribution of water. Yet there were very early sanitary principles described in the Mosaic provisions with reference to the Israelitish camp for removing and burying excreta. Diseases of the most serious character, such as consumption and rheumatism, were the constant effect of damp walls, which were frequently to be found in old houses as well as in those just newly built. It was proved, again, that where the sub-soil drainage of the sites of towns had been effected, phthisis had been reduced by one-half. On the other hand, where emigrants were located on undrained land fully half their children died from insanitary conditions soon after their fifth year. By the ancient law of Sparta, children who were weaklings were destroyed, but in our day it was found that by the application of modern sanitary science to children in their earliest infancy the weaklings were preserved and made good and profitable subjects in a strengthened and prolonged after-life. In conclusion, the lecturer said that the great principle of sanitation upon which it was necessary to insist was circulation *versus* stagnation. The only true and vital sanitary plan was the drawing away at every moment, by an increasing central mechanical power, all the dead human and other animal excreta of communities, and the casting of such excreta upon the land undecomposed, so that they might through the intermediate work of plants break out into life again, and give sustenance to man and animals. An examination of the work of the past seemed to open out a great future, especially for the working classes of the population. Under sanitation, every family might some day be provided with a dwelling-house well drained, well warmed, well ventilated, well lighted, well supplied with water, and with all comforts for the preparation of food and for the enjoyment of wholesome repose.

UNIVERSITY COLLEGE (MEDICAL FACULTY) ANNUAL DINNER.

ABOUT one hundred and forty old and present students of the Medical Faculty of University College met together for their annual dinner on Oct. 1st in the large general library of the College. Mr. William Cadge of Norwich took the chair and was supported by Mr. Erichsen, the President of the College, Dr. R. Quain, F.R.S., Dr. Russell Reynolds, F.R.S., Dr. Graily Hewitt, the Professors of the Medical Faculty, the members of the hospital staff, and old students of the College of almost every period since its foundation. After the customary loyal toasts, the chairman, who was received with great enthusiasm, proposed "Success to University College." After reviewing shortly the causes which led to the foundation of the College, and, alluding to the stimulus it had given to the higher medical education in this country, he expressed his belief that the almost filial love with which its old students look on the College was not due, as it well might be, to the many considerations which might well create a pride in it, but rather to the fact that within its walls they spent the first years of their real education, and laid the foundation of that knowledge which it had been the work of their lives to increase and mature. In conclusion he said, "Let us, then, with all these reminiscences of the past, with proof in abundance that earnest work is the feature of to-day, and with the confident belief that the future will equal or excel the past—let us with full hearts and glasses drink to the success of University College." The President of the College replied in eloquent terms, and concluded his speech by proposing the health of the old students, for whom Dr. Quain, F.R.S., replied. The last toast, the "Health of the Chairman," was proposed by Dr. Ringer, F.R.S., and was drunk with the greatest enthusiasm. During the evening an excellent selection of vocal and instrumental music was given by Dr. F. Roberts, Mr. S. H. Burton of Norwich, Professor Ramsay, and Mr. A. H. Powell of Beckenham.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF INSPECTORS OF THE MEDICAL DEPARTMENT OF THE LOCAL GOVERNMENT BOARD.

On the Sanitary State of the Blackburn Rural District, by Dr. PARSONS.—This report has but little interest beyond the story it tells as to lax sanitary administration, with concurrent needless sickness and death. The houses are in part badly constructed as regards foundations, want of damp-course, proper ventilation, and drainage; and this applies to new houses as well as to old ones. An absence of sewers and very imperfect methods of drainage are also referred to; and the closet accommodation is defective in amount, and is further a source of nuisance owing to faults of construction, dilapidation, and otherwise. Parts of the district have their water from the works of the Blackburn Corporation; elsewhere there are supplies which are liable to be fouled. And notwithstanding the provisions of the Public Health (Water) Act, and the withholding by the medical officer of health of the necessary certificates as to a proper water-supply, the authority allow new dwellings to be occupied. Details as to these various matters are given with regard to the several places in the district, together with statements as to occurrences of such diseases as enteric fever; and further evidence is afforded that where the attention of the authority has been drawn to sanitary defects, and even where notices have been served to remedy them, the matters have been simply allowed to rest. So again the authority complain that they need urban powers; but, as Dr. Parsons points out, they have all the necessary urban powers as to water-supply, sewerage and drainage, and nuisances, and when urged to procure additional ones so as to deal with new buildings, they had declined to do so on the ground that it would involve expense. Fortunately this latter error has been remedied since the report was written, and it is to be hoped that further action will also be taken as to the other matters calling for improvement.

On Epidemic Diphtheria at Sowerby Bridge, by Dr. PARSONS.—The physical and sanitary features of this Yorkshire town, with a population of some 10,000 inhabitants, are largely regulated by its position on the steep slopes of a narrow river valley; the houses being packed together, as a rule back-to-back, in rows one above another on the hill slopes. Some buildings, indeed, constitute a triple house; one a front house, the next a back house, and below a cellar house, one of them being entered from a gallery. Apart from some need for further ventilation of sewers the sewerage system presents no special features, but the interiors of the old houses remain in direct communication with drains by

Digitized by Google

means of sink-pipes. Water did not come under any suspicion, and the disposal of excreta and refuse presented no unusual features. According to the former medical officer of health, Dr. Britton, there were some deaths from diphtheria in Sowerby Bridge in 1882-83, and this after some years of freedom from the malady. In 1885 again diphtheritic croup is spoken of as having attacked many, the cause being very obscure. Between 1885 and the close of 1888 nothing further than three "croup" deaths came under notice. But between October, 1888, and May, 1889, 94 households were invaded with diphtheria, 131 cases and 27 deaths occurring. Of 128, concerning whom information was procured, 84 were children between four and fourteen years of age, which may be looked upon as the school-going age; and the outcome of a somewhat laborious investigation is to the effect that one child living in a somewhat damp situation between the canal and river, having in Oct., 1888, suffered from a throat affection which Mr. Horsfall, the present medical officer of health, cannot but regard as one of diphtheria, seventeen attacks followed in November in the school which she attended; and later on the disease attacked other schools, as well as children attending no school at all. Mild attacks, not recognised as diphtheria until the advent of sequelæ, tended to the spread of the disease, and in this way, exclusion of scholars from school who were known to have illness in their houses, failed to stay the malady. School closure, however, for a month stopped the further progress of the disease amongst the children attending the Board schools. Sanitary circumstances can only have played a very incidental part in the diffusion of this outbreak, and Dr. Parsons only refers to the entrance of sewer air into houses in this connexion, adding that there was no conclusive evidence as to its influence. Unfortunately the only hospital available was at Halifax, three miles away, and as a consequence no attempt was made to use it to isolate first cases of diphtheria.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Maidstone Urban District.—Mr. Matthew Adams records the death-rate of this district as 14·4 per 1000 during 1888, and in a tabular form he shows how marked a diminution has taken place since twenty years ago, when the rate was constantly about 25 per 1000. The most serious item in the death-returns consists of 12 deaths from diphtheria—the highest mortality since 23 deaths were distributed over the two years 1882-83. Last year 41 cases were heard of, a special outburst taking place in the district of Tovil. A connexion between this disease and both scarlatina and measles has often been suggested, and Mr. Adams states his belief that it is a real one. And he is inclined to the view that diphtheria generally follows the former diseases, a continued prevalence of which in some way prepares the way for the diphtheria, possibly by reason of the production of excretions favourable to the growth of the specific organism of the disease. But, at the same time, he is none the less convinced that bad sanitary surroundings, and especially bad drainage, often constitute the proximate cause of diphtheria, and he proceeds to enforce this view by recording recent experiences. We regret to learn, incidentally, that the dipththeria of the past year has continued into the present one, and that the causes of its persistence are by no means clear, although they are constantly subject to every investigation on which the ample means at Mr. Adams's disposal can be brought to bear. The system for the disposal of excreta in Maidstone, and the unsatisfactory state of some of the sewers and drains, are matters that would at any time have been important; at the present moment it is most urgent that they should be remedied so as to eliminate all possible causes of persistent disease, and at the same time give a better tone to the general sanitary circumstances of the town.

Stafford Urban District.—Dr. Milnes Blumer estimates that, owing to trade depression, the population of this district has diminished by about 600, and that it now stands at 18,923, on which the death-rate for 1888 would be 21 per 1000; or if corrected for outside deaths in the borough public institutions, 16·9 per 1000. The infantile death-rate was low—namely, 113 per 1000 registered births, and only one such death was due to diarrhœa. Infectious diseases were not numerous or fatal; and it is stated that the clauses as to compulsory notification continue to work smoothly. But, in connexion with certain occurrences of diphtheria and enteric fever, the contamination of local wells is referred to, a condition which should lead to active measures for the abolition of such sources of supply. The question of providing a permanent isolation hospital is to come under consideration. As to this, we would remark that any authority having compulsory powers as to notification would do well to possess such proper means of isolation as they can be assured of having access to at any moment that may be necessary. The existing arrangement, apart from small-pox cases, is with the infirmary authorities, and does not appear to be of this sort.

Batley Urban District.—After dealing with the question of lead-poisoning by water, to which we have elsewhere adverted, Dr. Swann goes on to point to some blemishes attaching to his district which are of very long standing, and which must tend to maintain a low standard of health. Thus he refers to houses either altogether without means of drainage, or fouling watercourses, or having old drains never yet connected with the new system; to houses befouled by contiguity to and soakage from the midden-privies which in this neighbourhood present nearly every feature which should be avoided; and to houses unfit for habitation by various reasons. Something, however, is being done as to midden-privies, but we very much fear it is not action of a sufficiently radical sort. New bye-laws are fortunately in prospect, and this may lead to a change in this respect as regards newly erected dwellings. The zymotic death-rate, though not low, is fortunately less than at any time since 1884, but Dr. Swann takes occasion to remind his authority that last year was one of exceptional death-rates in the country generally, and that nearly an eighth of the year's deaths were in Batley due to causes generally regarded as preventable. The death-rate from all causes was 17·3 per 1000.

Romford Rural District.—Diphtheria was the most important of the infectious diseases occurring in this district during 1888, and a local epidemic of it took place at Ilford, where it is mainly attributed by Mr. Alfred Wright to escape of sewer air from the street ventilators. Some special danger from this cause arises from the fact that in certain sewers the fall is so insufficient as to admit of stagnation of contents, and it is urged that, unless this be dealt with by effective flushings, further danger is likely to arise in the more densely peopled parts of the district. Indeed, after such flushings in the summer of last year, the disease at once ceased. One part of Hornchurch is also spoken of as in a bad sanitary state for want of proper drainage. The general death-rate of the district for last year was comparatively low, namely, 13·6 per 1000 living.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN twenty-eight of the largest English towns 5541 births and 3219 deaths were registered during the week ending Oct. 5th. The annual rate of mortality in these towns, which had steadily increased in the preceding four weeks from 16·2 to 17·9 per 1000, declined again last week to 17·6. During the thirteen weeks of last quarter the death-rate in these towns averaged 18·6 per 1000, and was 1·6 below the mean rate in the corresponding periods of the ten years 1879-88. The lowest rates in these towns last week were 10·1 in Derby, 10·7 in Leicester, 11·6 in Cardiff, and 13·2 in Birmingham. The rates in the other towns ranged upwards to 24·0 in Wolverhampton, 25·3 in Newcastle-upon-Tyne, 25·7 in Sunderland, and 25·8 in Manchester. The deaths referred to the principal zymotic diseases, which had been 537 and 529 in the preceding two weeks, further declined last week to 403; they included 147 from diarrhœa, 63 from diphtheria, 62 from "fever" (principally enteric), 52 from scarlet fever, 45 from whooping-cough, 34 from measles, and not one from small-pox. These zymotic diseases caused no death last week in Derby or in Huddersfield, and the highest death-rates in Salford, Wolverhampton, and Plymouth. The greatest mortality from diarrhœa occurred in Brighton, Salford, Bradford, and Wolverhampton; from "fever" in Manchester, Birkenhead, Leeds, and Salford; from scarlet fever in Bolton and Plymouth; from whooping-cough in Preston and Bristol; and from measles in Bradford, Sunderland, and Preston. The deaths from diphtheria included 45 in London, 7 in Manchester, 5 in Salford, and 2 in Liverpool. Small-pox caused no death in any of the twenty-eight great towns;

Digitized by Google

and no small-pox patient was under treatment at the end of the week either in the Metropolitan Asylum Hospitals or in the Highgate Small-pox Hospital. The number of scarlet-fever patients in the Metropolitan Asylum and the London Fever Hospitals at the end of the week was 1299, against numbers increasing in the preceding fourteen weeks from 559 to 1247; 149 cases were admitted to these hospitals during the week, against 196, 128, and 166 in the three previous weeks. The deaths referred to diseases of the respiratory organs in London, which had been 142 and 189 in the preceding two weeks, further rose last week to 225, but were 22 below the corrected average. The causes of 68, or 2·2 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Bradford, Sunderland, Nottingham, and in eight other smaller towns; the largest proportions of uncertified deaths were registered in Hull, Huddersfield, Oldham, and Liverpool.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 16·4 and 18·8 per 1000 in the preceding two weeks, was 18·6 in the week ending Oct. 5th; this rate exceeded by 1·0 the mean rate that prevailed during the same week in the twenty-eight large English towns. The rates in the Scotch towns ranged from 11·6 and 14·0 in Paisley and Greenock to 20·4 in Glasgow and Leith and 22·2 in Perth. The 476 deaths in the eight towns showed a decline of 5 from the number in the previous week, and included 16 which were referred to diarrhœa, 15 to whooping-cough, 13 to diphtheria, 11 to "fever" (typhus, enteric, or ill-defined), 8 to measles, 6 to scarlet fever, and not one to small-pox; in all, 69 deaths resulted from these principal zymotic diseases, against 74 in each of the preceding two weeks. These 69 deaths were equal to an annual rate of 2·7 per 1000, which exceeded by 0·5 the mean rate last week from the same diseases in the twenty-eight English towns. The fatal cases of diarrhœa, which had been 38, 36, and 30 in the previous three weeks, further fell last week to 16, of which 7 occurred in Glasgow and 3 in Dundee. The deaths from whooping-cough exceeded the number in the previous week by one, and included 11 in Glasgow and 2 in Paisley. The 13 deaths from diphtheria showed a further increase upon recent weekly numbers; 4 occurred in Leith, 3 in Glasgow, and 3 in Edinburgh. The deaths referred to "fever," which had been 6 and 11 in the preceding two weeks, were again 11 last week, and included 6 in Glasgow and 2 in Greenock. The fatal cases both of measles and of scarlet fever showed an increase. Four deaths from measles occurred in Aberdeen, and 3 (both of measles and of scarlet fever) in Glasgow. The deaths referred to acute diseases of the respiratory organs in the eight towns, which had been 66 and 89 in the preceding two weeks, further rose last week to 99, and exceeded by 20 the number in the corresponding week of last year. The causes of 42, or nearly 9 per cent., of the deaths registered in the eight towns were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 18·6, 24·5, and 31·5 per 1000 in the preceding three weeks, declined again to 26·2 in the week ending Oct. 5th. During the thirteen weeks of last quarter the death-rate in the city averaged 24·0 per 1000, the mean rate during the same period being 16·5 in London and 15·9 in Edinburgh. The 177 deaths in Dublin last week showed a decline of 36 from the number in the previous week; they included 12 which were referred to diarrhœa, 7 to "fever" (typhus, enteric, or ill defined), 3 to whooping-cough, 1 to measles, and not one either to small-pox, scarlet fever, or diphtheria. Thus the deaths from these principal zymotic diseases, which had been 20, 31, and 30 in the preceding three weeks, declined again last week to 23; they were equal to an annual rate of 3·4 per 1000, the rate from the same diseases being 1·9 in London and 1·4 in Edinburgh. The deaths attributed to diarrhœa, which had increased in the previous four weeks from 11 to 23, fell again last week to 12; the 7 deaths from "fever" exceeded the number in the previous week by one. The deaths both of infants and of elderly persons were fewer than those returned in the previous week. Four inquest cases and 4 deaths from violence were registered; and 46, or more than a quarter, of the deaths occurred in public institutions. The causes of 34, or more than 19 per cent., of the deaths in the city were not certified.

THE SERVICES.

ARMY MEDICAL STAFF.—Surgeon-Major Sidney Key worth Ray to be Brigade Surgeon, ranking as Lieutenant-Colonel, vice W. Folliott, F.R.C.S. Ireland, granted retired pay (dated Sept. 25th, 1889).

ARMY MEDICAL RESERVE OF OFFICERS. — Surgeon William John Naismith, M.D., F.R.C.S. England, to be Surgeon-Major, ranking as Major (dated Oct. 9th, 1889).

ADMIRALTY. — The following Surgeons have been promoted to the rank of Staff Surgeon in Her Majesty's Fleet—viz., James Porter, M.A., M.B., Charles James, Thos. Loane, M.D., John Bellhouse Bowden Triggs, M.B., George Robert Deighton Charlton, George Warner Bell, and Francis Austen Jeans (dated Sept. 29th, 1889).

The following appointments have been made:—Surgeon Horatio S. R. Sparrow to the Royal Marine Artillery at Eastney; Mr. Frederick D. Lawson to be Surgeon and Agent at Bridlington (dated Oct. 9th, 1889).

ROYAL NAVAL ARTILLERY VOLUNTEERS (Clyde Brigade). Surgeon James Cowan Woodburn, M.D., to be Staff Surgeon (dated Sept. 24th, 1889).

VOLUNTEER CORPS.—*Engineers* (Fortress and Railway Forces): 1st Devonshire and Somersetshire: Acting Surgeon M. L. Brown, M.D., resigns his appointment (dated Oct. 5th, 1889).

Correspondence.

"Audi alteram partem."

MEDICAL EDUCATION.

To the Editors of THE LANCET.

SIRS,—I am glad to see that the seed I cast upon the soil in my address on Medical Education to the members of the British Medical Association is not unlikely to be fruitful, and that in at any rate two very highly cultivated fields it has taken root, and is already well above the ground. I allude to the addresses delivered at the opening of the medical session at the Yorkshire College in Leeds by Professor Gairdner of Glasgow and at the St. George's Hospital Medical School in London by Dr. T. Clifford Allbutt respectively. I desire nothing more in the interest of medical education than that the subject should be thus freely discussed, that the voice of the profession at large should be heard upon it, and that professional opinion concerning it should, as far as possible, be fully elicited. The ground I took in my address is that, as matters stand at present, the student at the close of his curriculum is not as well prepared as he ought to be, and might be, to cope with the responsibilities of general practice, and that he needs something for which that curriculum has not provided—viz., a knowledge of the more common forms of ordinary illness. He may be, no doubt he is, well versed in the general principles of his profession. He may possess, he unquestionably does possess, in the aggregate a vastly greater amount of medical and surgical knowledge than the recently equipped practitioner of a former age, and yet, for a time at any rate, he is not his equal, inasmuch as he lacks the groundwork and the foundation upon which all his work should rest. My argument is this, that in former times, when the old-fashioned system of apprenticeship was in vogue, the student had the opportunity, greater or less, as the case might be, to see the daily routine of medical practice, of making himself acquainted with ailments and illnesses of which he can see nothing in his hospital experience, and of picking up a vast fund of knowledge whose utility would be of inexpressible value to him to the last day of his career; that *in altogether abolishing apprenticeship* a false step has been taken, and that medical education has been to some extent impoverished. And this, notwithstanding all that may be said by ultra-educationists, and by those who place theoretical knowledge so far in advance

Digitized by Google

of practical experience, is, I believe, the opinion honestly entertained by a very great majority of thoughtful medical men of our time. No one values a university education more highly than I do; no one longs more earnestly and profoundly than I that every medical student could enjoy so incalculable a privilege; but what cannot be cannot be, and, for those to whom the university is an impossibility, I hold that the best *attainable* means should be provided. You will now, I am sure, permit me a few words in reply to Professor Gairdner and to Dr. Clifford Allbutt respectively, especially as those words are clearly needed to prevent misunderstanding. The words in my address to which, in each instance, apparently, objection has been taken are as follows:—

"*Medical Education in the Present.*—Year by year and little by little we have been accumulating a burden which, if not absolutely more than the shoulders of the student can bear, is yet heavier than he can possibly carry with credit; and, instead of increasing his opportunities to acquire the strength necessary to bear it, we have curtailed his time, have deprived him of material advantages, and, in accordance with the hurry of the age, have demanded results well-nigh impossible of attainment. The five years of apprenticeship have been swept away, and with them the opportunity to master the groundwork of medical education and to acquire a sound knowledge of the more common forms of ordinary illness has gone also; and in four years, instead of eight, we permit the whole work to be completed. We have determined to ignore the utility of that homely but infinitely useful form of preparation for the higher parts of medical education which apprenticeship or pupilage was pre-eminently calculated to afford; we have determined that from the day on which a boy has been able to pass a very ordinary and limited educational examination he shall be permitted to take his place in a medical school, and we have arranged a curriculum which, if by dint of slavish toil he can master, shall enable him, at the early age of twenty-one, to enter upon the full responsibilities and duties of practice."

Dr. Gairdner's objection comes practically to this, that this familiarity with the conditions which will form the actual environment of the medical man not only in his earlier years but all through his life *is not necessary;* that his general education in the principles of his profession will secure him from disaster; and that experience will come with time; and he goes on to reason that, if it is necessary for him to have *seen* and *done* all the lesser, he ought by parity of reasoning to have also seen and done all the great things also. My answer is, by all means let him have seen, done, handled, and operated on everything that is possible; at least, let him have seen them done by competent hands. Let him, under skilled guidance, have himself performed all the minor operations—the operations he may be called upon to undertake the day he enters on practice; and for the major ones, let him so practise them *on the dead subject*, and so use his eyes and his head, when he sees them done on the living one by his teachers, that when the day of responsible surgical emergency comes upon him, he may feel that he is honestly prepared to meet it. The hospital, or school, or university in which all this cannot be provided must be a poor one indeed; and the "authority" which is satisfied with less falls short of the calls of duty. With the wish so earnestly and eloquently expressed by Dr. Gairdner, that a "few things should be learned thoroughly and well," I am entirely in accord; but can Dr. Gairdner be in earnest in believing that half-a-dozen cases of pneumonia, or of Bright's or any other disease, studied ever so deeply, will stand in the stead of the practical ability to relieve a distended bladder or to reduce a dislocated joint? Can he mean that because a man has with ever so great earnestness, studied "a few cases" to the utmost bounds concerning them, that it is therefore not necessary that he should know measles from scarlet fever, nor be able to recognise small-pox, typhus, or typhoid fevers when he sees them? I cannot credit so great a man with a fallacy so awful, even though his own hand wrote it. And where, except in the homes of the people, is the student to become conversant with these things? not in the general hospitals attached to our schools and universities, for from these they are rigidly and righteously excluded, but *only* in the homes of the people, and to these he has no access except through the general practitioner, or some one of the many public charities, other than the hospitals, with which our happy land is so freely studded. For this state of things I propose a remedy, and the *remedy itself* is one which, I venture to think, meets with very widespread approval, the difficulty being, not the remedy, but the time at which it may most advantageously be taken. On this subject again my words are these:—

"*The most Advantageous Time for Pupilage.*—I hold that the time to acquire simple information is when the mind is eager, inquiring, impressionable, and plastic. In our large county hospitals, workhouse infirmaries, and public dispensaries, which, up to the present time, have been but very slightly utilised, we have a splendid field in which a vast fund of information of this kind which now runs to waste might be gleaned, and of these I would make much greater use than has hitherto been the practice. In pupilage, in one or other of these, in my humble judgment, *a year, or even two,* at the commencement of professional study would prove the very best beginning; and in following the practice to be there seen under the direct guidance and supervision of those who administer them, a youth would see work which in after life would be of incalculable value to him, and would obtain opportunities for a groundwork which, under the present method of education, are wholly thrown away."

I think Dr. Clifford Allbutt can hardly have read my address, for I do not think he would wilfully misrepresent me on so very grave a subject; and yet in his address to the students at St. George's Hospital these are the words he uses:—

"Mr. Wheelhouse proposes to make this state of things ten times worse than before. By submitting youths to a five-years' apprenticeship to working doctors at a time when their minds are expanding and impressionable, at a time when an ardent love for higher study and a yearning for ideas spring up in the heart, he would send them not where they can feel the influence of great men present and past, not where learning is seen in all her variety and in all her provinces, not where they may associate with men of their own age whose minds are occupied with other forms of culture and in training for other callings, but a student is to be confined to one mind, however able, to one profession, however honourable, to one set of ideas, however fruitful. And, as a matter of fact, we know that the ruling mind will often be something less than great, the set of notions too often vulgar, and the teaching at best a teaching and not a cultivation. Gentlemen, this is but to perpetuate the common-mindedness which I suggest is already our danger—a fault due in part to our defective education, in part to our lack of leisure. I say we are already too narrow and channelled in our thoughts, and too shoppy; and we are to improve our education by intensifying this very habit of mind. We are to make our education more comprehensive by shutting up our students with individuals; we are to strengthen their reasoning powers by therapeutical drill; we are to substitute the ideas of the middle-class parlour for the traditians of a university! But one may get roast pig without burning down one's house, and I contend—with an exception to be hereafter discussed—that a man whose mind has been enlarged and strengthened by a university course will, after a briefer drill, make a more skilful practitioner than one whose technical craft is gained by routine and is not vitalised by a comprehension of principles. It is no truism, gentlemen, to repeat in this place that knowledge is one and indivisible, and that he who is content to pick up isolated chapters of learning has no living knowledge at all."

Now, all this as mere declamation is of course superb, and if it were a correct version of the matter in question I would not utter a word; I would sit silent, abashed, and crushed. But as it is exactly the reverse of anything I have ever said, or thought, or written, I cannot permit it to pass without observation and correction. *I would rather go on as we are, greatly as I consider that our plan might be improved, than that we should go back to the system of a five-years' apprenticeship to one man or to one institution.* I hold, and I have ever taught, that to go back to that system would be to waste, hopelessly and absolutely, three years of the very best part of every educational life. My words are clear and explicit, and are not open to the construction put upon them by Dr. Allbutt. "That *one*, or even two years devoted at the commencement of professional study to the acquirement of a knowledge of the ground work, and of the observable phenomena of our science, under the supervision of competent teachers, in some of the insti-

Digitized by Google

tutions whose infinitely valuable opportunities are, under the present order of things, entirely wasted would be of incalculable value." And with this opinion Dr. Allbutt, after all, does not appear to disagree, for, a little further on in his address, we find him actually advocating such a measure.

"Nevertheless, I agree with Mr. Wheelhouse that an apprenticeship to the domestic side of your work, a familiarity with its lesser marks and byeways, is necessary. These we cannot teach here. After your faculties are trained and strengthened in their main branches, your lesser shoots shall be duly laid in. But with capacities thus enlarged, one year's apprenticeship would do the work of five in earlier age; and an obligation upon young men thus to apprentice themselves before the completion of their studies would have my approbation and active support."

Wherein, then, lies the great difference between us? Simply as to the time (the old, old question) at which pupilage may be most advantageously taken. I think that rudimentary knowledge should be sought in the earlier years of studentship. Dr. Allbutt, in common with many others, would place it later on; and when a man's mind *has* been expanded by converse with his fellows and by the scientific observation of the phenomena of disease, and is truly and rightly aflame after higher knowledge, higher reasoning, and higher aspirations, he would put him back to the bare study of the Pharmacopœia, and to the acquirement of those rudiments of medical education which can only then be a weariness to his soul and a degradation to his energies. The difference between us, infinitely great as it is, is not one of "principle" after all, but only a question as to the choice of time, and is hardly such as to call for the old story of the Chinaman, who was so devoted to roast pig that he was ready at any time to burn his house down that he might revel in his favourite dish.

I am, Sirs, your obedient servant,

Leeds, October, 1889. C. G. WHEELHOUSE.

WHY DOES THE UTERUS CONTRACT DURING PREGNANCY?

To the Editors of THE LANCET.

SIRS,—Under the above heading, in your last issue, Mr. Wade of Chudleigh, in a letter throwing out a suggestion as to the cause of these contractions—namely, the presence of blood overcharged with carbonic acid, says: "We have the authority of Playfair for the statement that the intermittent contractions of the uterus occur every five or ten minutes, sometimes oftener, rarely at longer intervals, throughout the whole of gestation." I hope it may not be considered a piece of unpardonable egotism if I take this opportunity of pointing out that the subject was first introduced by me in a paper read so long ago as Oct. 4th, 1871, before the Obstetric Society of London, and subsequently added to in papers on the same subject at three International Medical Congresses, and published in their proceedings. The first paper will be found in the Obstetrical Transactions, London, vol. xii. In it, page 219, I remarked: "It may be that the semi-stagnant state of the blood (that is, of course, charged with carbonic acid) in the uterine sinus &c. may provoke contractions, but certainly there is some other excitor than either fœtal movements or the irritation of the various nerves in sympathetic connexion with the uterus." Of course this suggestion is the same in essence as Mr. Wade's; but we both derive our inspiration with the idea thrown out, I think, by Brown-Séquard—namely, that the presence of carbonic acid in excess in the uterine sinuses causes the uterus to contract. I cannot find that he gives "much evidence in proof, but it is a fair working theory; and I also think it may be assumed as one of the factors in the genesis of labour." But there are other agents concerned in the movements of the blood in the walls of the uterus and placenta; and to these I have called attention in a note published in the Proceedings of the Royal Society, 1879: "Note on the Auxiliary Forces concerned in the Circulation of the Pregnant Uterus and its Contents in Woman." These transcendental points seldom get into text-books where Mr. Wade has been looking, or if they do, it is many years after their introduction; and even some text-books of modern date have altogether omitted noticing these contractions and the great help they give in the diagnosis of pregnancy. Mr. Wade, however, remarks: "We are all familiar with the facts that the chorionic villidip freely into the sinuses of the uterine wall, and that in this situation an exchange takes place between the fluids on the fœtal and maternal sides of the villous membrane which alone separates them." I am quite willing to concede an exchange, but not through one membrane alone; and I cannot include myself in the "all," as may be seen in my "Anatomy of the Human Placenta" (Obstet. Trans. Lond.). However this may be, if Brown-Séquard's theory be correct, the retention of semi-stagnant blood, highly and increasingly charged with carbonic acid and effete fœtal matter, is probably the immediate stimulus required to produce the uterine contractions I have pointed out, and which acts as a supplementary heart. The contractions act, it should be observed, independently of any external irritation. Up to the present time I have had no co-worker in this subject; when other observers take it up, probably newer points will be brought to light.

I am, Sirs, yours obediently,

J. BRAXTON HICKS.

George-street, Hanover-square, Oct. 3rd, 1889.

REMARKABLE SURVIVAL AFTER MULTIPLE PISTOL-SHOT WOUNDS.

To the Editors of THE LANCET.

SIRS,—The following case may interest those of your readers who perused the articles in THE LANCET of Sept. 14th, 21st, and 28th, under the heading, "Five Cases Illustrative of Cerebral Surgery."

On the evening of Oct. 13th, 1881, W. L——, aged twenty-one, a rural postman, was seized by a would-be assassin, who fired several shots at him from a revolver, and having expended his own ammunition, called to a companion to "have at him now"; this man then continued the attack, and fired into their victim. *One of the bullets entered the brain, where it still remains, and causes little if any inconvenience*, although for nearly two years he could not bend his head or lean forward without giving rise to great pain and unpleasant symptoms. On making my examination I found a bullet wound on the left side of the head, about half an inch posterior to his ear, and immediately beneath the parietal eminence. Through this wound the brain substance exuded, and a small probe passed directly inwards for a distance of about two inches by merely letting it drop into the wound. On examining with tip of little finger, no spicula could be found. Another bullet entered the left temple just above the zygomatic arch, about an inch and a quarter from the edge of the orbit; it took an inward and downward direction; its course, however, could not be traced. Another hit the angle of the jaw, took an upward direction, and was held between two molar teeth. One entered the left side of the chest on a line with the nipple, an inch and a half posterior to it, passed through the chest, and was extracted from the right axilla. One glanced off the great trochanter, and became lodged in the lumbar muscles. Two passed through the forearm about the middle. One entered the forearm about two inches from the wrist, took an upward course, and was extracted near the elbow-joint. One passed through the hand between the thumb and index finger. The skin on the left forearm and wrist was destroyed, the clothing having been set on fire by the powder. On the right hand the metacarpo-phalangeal joint was destroyed by the charge from a pistol loaded with shot, several grains of which and some of the paper used for "wad" were extracted from the palm of hand. The man was almost pulseless, and, the case seeming hopeless, it was decided by Dr. Allen and myself not to interfere except symptoms demanded it further than to cleanse and dress the wounds, carbolic lotion being used. He was given brandy and new milk or beef-tea every half hour. Coughing was severe for some days, and there was considerable hæmorrhage from the lungs. He had also a sharp attack of double pneumonia. He was kept perfectly quiet and cool, morphia being given in minute doses hypodermically to relieve the cough, which caused terrible pain in his head. On the fifth day after being wounded he had considerable delirium, and could hardly be restrained, as he was "afraid of being taken to an asylum" at one time, while at another he thought his assailants were again attacking him.

This case, besides being interesting, I consider very important from the fact that, although being so fearfully wounded, the man did not lose consciousness till some time after he was brought to the police barracks, where he described one of his assailants and fully identified him. He was also able to describe a man who passed him soon after the attack; he also dragged himself to a house a few

Digitized by Google

yards from the outrage, begged to be admitted, and when refused, and feeling faint, hid the mail bags, and after "coming to" crawled to another house, prayed for admission, and to send for a priest. Being again refused, he "dropped down to die." He has no idea how long he lay there, but hearing a car pass he made an effort, and got to the road, where he was found in a fainting state by the police sent to look for him. The bullets removed were ·450, or about the same size as those used for the British bull-dog revolver. I am, Sirs, yours faithfully,

County Infirmary, Longford, Oct. 3rd, 1889. N. MAYNE.

EXFOLIATION OF ALVEOLAR PROCESSES.

To the Editors of THE LANCET.

SIRS,—I see Mr. R. Clement Lucas, in giving notes of two cases of necrosis of the alveolar processes following measles, which appeared in your last impression, says that he does not know of any case of typhoid fever resulting in exfoliation of the alveolar processes of the jaws. As such a case occurred in my practice a year ago, it is perhaps of sufficient interest to place on record.

W. H——, a lad of sixteen, sent for me on Aug. 30th, 1888. I found a well-marked case of typhoid fever, and the patient for a fortnight, or the latter half of September, was in a semi-conscious condition, requiring rousing for a part of that time to take nourishment &c. On Oct. 10th the left half of the lower maxilla was noticed to be swollen, and afterwards there was fetid breath with foul-smelling mouth and gums. On the 17th he had pulled out the two lower left incisors, and the canine molars were found to be loose, whilst the alveolar process was also loose and evidently necrosed. He was sent to the London Hospital, his friends not being able to stand the drain on their resources, and the alveolar process, including the sockets of all the teeth of the left half of the lower maxilla, eventually was taken away, leaving the lad one side of his face fresh and juvenile and the other side very grandmotherly looking indeed.

I am, Sirs, yours truly,

MILLICE CULPIN, L.R.C.P., L.R.C.S.Edin.

Stamford-hill, Oct. 5th, 1889.

NAPHTHALIN.

To the Editors of THE LANCET.

SIRS,—May I ask for space to add my testimony to the value of naphthalin in the class of case Dr. Angel Money refers to in his letter published in your last issue? In conjunction with the diet advocated by him, I have found nothing so serviceable as the drug in question. It is equally serviceable in the epidemic infantile diarrhœa for which Nottingham occupies an unenviable position, together with Leicester and Oldham.

I am, Sirs, your obedient servant,

Nottingham, Oct. 7th, 1889. LEWIS W. MARSHALL.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

The Session 1889–90.

ON all sides the work of the coming session has begun. The Owens College had its opening day on the 1st inst., when Professor Schuster delivered the inaugural address, taking for his subject, "University Teaching in its relation to the Industrial Application of Science." This makes the fortieth session of the College, and the few who can look back and remember the first of these must be struck by the rapid and wonderful strides the College has made in arriving at its present position. On the same day the half-yearly meeting of the court of governors was held, an interesting feature of which was the presentation to the College by a number of subscribers of a portrait of Mr. Alfred Neild, who for a considerable length of time has been its treasurer. The financial report for the past year was satisfactory, the expenditure having kept within the income. On the evening of the same day the medical department of the College had its own special opening in the shape of a soirée, at which nearly a thousand visitors were present. The guests were received by the dean of the medical school (Dr. Young), and several members of the court of governors &c. Subsequently the dean presented the report for the past year, which shows a highly satisfactory condition of the school from every point of view. Various exhibits, demonstrations, drawings &c. were provided for the amusement and instruction of the visitors, and Professor Dreschfeld gave a very interesting *résumé* of our present knowledge concerning leprosy. On Wednesday, the following evening, the first meeting of the Medical Society was held, and, following a practice which appears to be becoming common, of inviting gentlemen from a distance to give papers at the opening meeting of our societies, Dr. Hughlings Jackson was asked to visit Manchester, and delivered an address upon "Respiratory, Toxic, and Traumatic Convulsions." On Friday evening next the annual medical dinner will take place at the Queen's Hotel, under the presidency of Dr. Little, and after then we may hope to settle down steadily to work all round.

The Proposed New Hospital.

It is with great regret that I have to record the fact that the munificent offer of the Whitworth trustees to Owens College of a sum of some £70,000 has been lost. The trustees undertook to provide money to erect a hospital with sixty beds, and endow it with £2000 per annum, to become the property of the College, but they wished it to be more or less connected with the Royal Infirmary, the latter body to take an active share in its management. After nearly twelve months of negotiations between the two bodies the Infirmary Board at its last meeting declared themselves unable to accept the conditions proposed, and the trustees have now withdrawn their offer. It is an open secret that the relations between the College and the Infirmary have for some time been considerably strained. The College authorities, as representing the medical school, desire to have some control over or voice in the arrangements for the clinical instruction provided for their students, but this the Infirmary has not been willing to accede to; other matters also have caused no inconsiderable friction between the two bodies, but it is to be hoped that in the interests of the Infirmary, the College, and the public at large, some *modus vivendi* may ere long be arrived at, and that this handsome proffered gift may not be irretrievably lost.

Salford and its Fever Hospital.

Owing to the great prevalence at the present time of scarlet fever and diphtheria in the neighbouring borough, great difficulty has arisen in providing hospital accommodation for all the cases which it is desirable to isolate; and it was stated last week that the wards of the Wilton Hospital are crowded far beyond their proper accommodation. If this be so, it is no light matter; for of all patients those suffering from infectious disease are the last that should be stinted in the proper cubic space and air-supply within their wards. In Manchester itself the cases of scarlet fever are also so numerous that the Infirmary Fever Hospital cannot take the surplus Salford patients; and hence the health authorities of the latter are seeking the help of the guardians to provide them with hospital accommodation at Hope. In the meantime the proposed new fever hospital for the Salford Corporation is still in the clouds.

Prevalence of Scarlet Fever.

During the present epidemic of scarlet fever, and now that the notification of infectious disease can, by means of the recent new Act, be easily put in operation, it is to be hoped that all the surrounding smaller districts will at once put it in force, and the whole of the population comprised in "Greater Manchester" thus be placed under the same conditions, so far as obtaining knowledge of the existence of these diseases is concerned.

Unhealthy Dwellings.

At last the Corporation has made a distinct move in grappling with this subject. At the last meeting of the City Council a "presentment" was made by the medical officer, condemning what has long been known as one of the most insanitary areas in the Ancoats district. It was this area to which Dr. Thresh a short time ago drew particular attention in a special report that he made thereon to the sanitary association. It is pleasing to note that Dr. Thresh's work has not gone unnoticed, and he has just been appointed officer of health to Chelmsford.

Manchester, Oct. 8th

NORTHERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENT.)

Newcastle.

FOLLOWING closely upon the opening of the new College of Medicine in Newcastle came the inaugural meeting of the session 1889–90 of the Northumberland and Durham Medical Society. This is the oldest of our medical societies, and was, I believe, originally started by Sir John Fife, Dr. Charlton, Dr. George Robinson, and others as the Newcastle and Gateshead Pathological Society. The opening address by Professor Lawson Tait was most instructive, and was listened to by all with much interest, his subject being "Ectopic Gestation in the Tubo-ovarian Tract." The annual dinner was held afterwards in the Assembly Rooms, Dr. James Murphy of Sunderland being the genial president, and he was supported by the Mayor and Sheriff of Newcastle as well as by many distinguished visitors. I believe that as many as 140 sat down to dinner. Professor Tait, in the course of a characteristic speech, said that the school he was connected with proposed seriously to offer to the College of Medicine of the University of Durham a series of negotiations of which he was for the moment personally the bearer. The proposal was founded upon details which it was far too early to discuss, because they had not yet been formulated, but which he hoped would be entertained by the Durham authorities, by which students of the Colleges of Science and Medicine of Birmingham might obtain degrees from Durham, and still be subservient to that University. He concluded an eloquent speech by saying he never saw anything more perfect in his life than the College of Medicine in Newcastle. He also paid a tribute to Dr. Heath, the president of the college, who had given a thousand guineas to its funds. I may mention that a donation of £200 has since been received for this object per Dr. Drummond. Dr. Heath said that as to the suggestions of Professor Tait, the proposed affiliation would, when brought before the College of Newcastle and the Senate of the Durham University in proper form, "receive their most serious consideration." As regards this meeting, it would be an omission not to say that great credit is due to Professor Oliver, the hon. sec., who spared no pains for the comfort of the very numerous guests who arrived from far and near to this large and very successful entertainment. On all hands I hear notes of satisfaction as to the arrangements.

Durham.

At a special meeting of the Durham Town Council held last week, Mr. Jepson of that city brought the condition of the overcrowded dwellings and the insanitary condition generally of the houses of the working classes before the board, and the result of his statements was the appointment of a special committee to take the matter into consideration. Mr. Jepson said that from what he knew there were no less than 3000 people living in Durham in overcrowded and unhealthy dwellings.—The Misses Pease of Southend have given £500 to the Darlington Hospital, to increase the efficiency of the nursing department.

Sunderland.

Professor Tait gave a demonstration at the Sunderland Infirmary last Saturday afternoon of his operation for ruptured perineum on two patients, and also (on the invitation of Dr. James Murphy) performed a salpingectomy.

Newcastle-on-Tyne, Oct. 8th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

EDINBURGH.

The Social and Sanitary Society.

A CORRESPONDENT writing to one of the Edinburgh papers calls attention to the excellent work that has been done in Edinburgh during the last five years by the Social and Sanitary Society. This Society has certainly done good service in reporting on the insanitary conditions of the houses and courts in the poorer districts of the city. Special attention has been paid to the water supply, and the recommendation of the Public Health Committee that the following regulations shall be enacted, may be looked upon as an almost direct outcome of the work of this Society. These regulations for the inspection of waste-pipes and the cleaning of cisterns are as follow:—1. The occupiers of houses and premises within the burgh shall at all reasonable times give access to the burgh engineer or other authorised sanitary inspector or officer, to examine water-cisterns and pipes and other apparatus connected therewith. 2. In the event of any cistern being found to be foul, the occupier of every such house or premises shall, within six days after receiving notice from the burgh engineer, effectually cleanse such cistern. And in the event of failure, the necessary work may be carried out under authority of the burgh engineer, at the cost of the occupier of such house or premises. 3. Without prejudice to the preceding regulation, all cisterns within the burgh, wholly or partially used for culinary or domestic purposes, shall be cleansed at intervals not exceeding six months. 4. In cases where cisterns exist for common use, and are so placed and used as that individual implement of the obligation to clean by the occupiers of such houses or premises and users of such cisterns is impracticable, such cisterns shall be cleansed by the burgh engineer, under direction of the magistrates and Council, at the rateable cost of the occupiers of the houses or premises using or deriving benefit from such cistern, as the same shall be apportioned and certified by the burgh engineer.

The Edinburgh Veterinary Colleges.

Last week work commenced in both the Edinburgh Veterinary Medical Schools. Very considerable interest attaches to the utterances of those connected with these Colleges, especially at the present time, when tuberculosis and pleuro-pneumonia occupy such prominent positions in the public mind and prints. Perhaps most attention was attracted to the address on "Protective Inoculation against Infectious Diseases with special reference to Rabies," which was given by Dr. Hime of Bradford at the Royal (Dick's) Veterinary College; but the addresses given at both institutions were full of interest, and promise well for the future of veterinary, medical, and surgical science and practice in Scotland.

New Assistant Surgeon for the Edinburgh Royal Infirmary.

For the new post of assistant surgeon several names have been suggested, but only three, so far as can be learnt, are actively working for the appointment—Dr. J. Shaw Maclaren, Dr. Scott Lang, and Dr. D. Wallace. In connexion with appointments, it is stated that Dr. Noël Paton has decided not to offer himself as a candidate for the new chair of Physiology in Dundee.

Edinburgh, Oct. 9th.

GLASGOW.

Faculty of Physicians and Surgeons.

AT the October meeting of the Faculty, held last Monday, the usual annual elections took place. Dr. James Morton retired from the presidentship. He had held office for three years, and had well maintained the dignity and honour of the Faculty. His letter (for he himself was unable to be present), in which he announced his demission of office, contained some sound and valuable hints as to the affairs of the Faculty, and was ordered to be engrossed in the minutes; it also contained a touching reference to his own serious illness, in which he has the warmest sympathy of every member of the profession in Glasgow and of very many beyond it. Dr. Robert Perry was elected president, and Dr. David Yellowlees was elected visitor. The contest for the office of Examiner in Midwifery resulted in the reappointment of Dr. Samuel Sloan. A good deal of irritation was displayed at the meeting regarding the high-handed conduct of the Royal Infirmary managers and St. Mungo's College governors in appointing on the boards representatives of the Faculty without nomination or election by the Faculty. The vacancies had occurred through the resignation of the Faculty's representatives during their term of office; doubtless both institutions acted within the letter of the law in themselves appointing to the vacancies, but it would have been much more courteous and decent had they obtained the mind of the Faculty before making any selection. The incident is the more awkward that one of the appointments is for three years. Another singular fact is this: that up till the present moment the Faculty has had no formal com-

Digitized by Google

munication from St. Mungo's governors to indicate what are its principles or rights in appointing representatives on the College Board of Governors. The Faculty knows nothing of its position as regards St. Mungo's except what it may have learnt through the public prints. The Council of the Faculty has, in fact, been instructed to examine into the Faculty's relation to St. Mungo's, and to report whether, in its opinion, it is desirable that it should be represented at all on the Board.

The Royal Infirmary.

At a meeting of Managers of the Glasgow Royal Infirmary held on Friday, the 4th inst., J. Lindsay Steven, M.D., assistant physician to the Royal Infirmary, was appointed pathologist and curator of the museum in the Infirmary. This appointment, under present arrangements, carries with t the lectureship on Pathology in this College.

Glasgow, Oct. 9th.

ABERDEEN.

The Aberdeen University Court.

AT the meeting of the University Court held on the 4th inst., the following gentlemen were appointed examiners for degrees: Anatomy, Mr. William Milligan, M.B., C.M.; Botany and Materia Medica, Dr. F. B. White, Perth; Chemistry and Medical Jurisprudence, Dr. Joshua L. Kerr, Manchester; Natural History and Institutes of Medicine, Dr. Thomas W. Shore, London; Practice of Medicine and Pathology, Dr. P. Blaikie Smith, Aberdeen; Surgery and Midwifery, Dr. A. D. Keith, Aboyne. At the same meeting Mr. H. F. Jones was appointed assistant to the Professor of Chemistry, and Dr. Alex. Macgregor assistant to the Professor of Medical Jurisprudence. The court had also submitted to it remarks by the senatus on the observations made by the University Courts of Glasgow and Edinburgh respectively on the report by the University Court of Aberdeen to the Privy Council in favour of certain alterations of the medical ordinances. The Court resolved to submit a statement to the Privy Council in accordance with the observations.

Health of the City.

During the past week the following cases of zymotic disease were reported:—Measles, 7; scarlet fever, 7; diphtheria, 2; typhoid fever, 4.

Aberdeen, Oct. 8th.

DUBLIN.

(FROM OUR OWN CORRESPONDENT.)

Sanitary Condition of Dublin during 1888.

LAST week attention was directed to Sir Charles Cameron's report for last year on the health of Dublin, and some further observations on the same subject may prove of interest. Of the 8894 deaths registered during last year, 2843, or 32 per cent., were of children under five years of age, and 2250, or 25 per cent., were aged sixty years and upwards. The deaths of infants under one year old were equal to 167 per 1000 births registered, which, high as it was, shows an improvement as contrasted with 1887, when the mortality rate was 200 deaths per 1000 registered births. Sir Charles Cameron is of opinion that the close inspection of the tenement houses which has been carried on for the past few years has resulted in a very substantial improvement of their condition, and must have been an important factor in the more satisfactory state of public health in Dublin recently shown. He considers Dublin is a city peculiarly well adapted for the water carriage of sewage; and although the contamination of the river Liffey by the sewage discharged into it is an evil which steadily grows greater as the water-closet system becomes more extended, he believes that a method of rendering the Dublin sewage innocuous could be adopted at a moderate cost provided that a "clarification" or "precipitation" scheme were carried out.

Royal Academy of Medicine in Ireland.

The seventh annual general meeting of the Academy takes place this year at the College of Physicians on Friday, Oct. 25th, when the annual report and statement of accounts will be submitted, and an election of office-bearers will take place.

Kingstown Main Drainage.

The main drainage of this the premier township is still under consideration, and, although some preliminary work has been done, it is the opinion of those who are best informed that eventually the matter will never be carried out. Whatever sewerage scheme is adopted, it is to be hoped that it will in no way injure the Sandycove bathing place, the best of the kind on the Dublin sea coast. It is thought by many that the intercepting sewer should be carried to Bullock, where the Kingstown township terminates. At present an open sewer discharges in front of Bullock Harbour, which in time will silt up the entrance to the harbour, and it is believed that the nearest and best outfall for the sewage at this point is the place known as Brandy Hole.

The Meath Hospital, Dublin.

The introductory address was delivered on Monday morning by the senior surgeon, Sir George Porter, Bart. Sir George concluded an admirable and eloquent address as follows:—"Men of my age contemplate with no little interest young and ardent spirits entering a profession such as ours. Visions of former days rise before us. The future is to you resplendent with a light and promise which pales and fades to us; but accept the lesson which experience has taught us: it is this, that a happy and prosperous professional life does not wholly, or even largely, depend on mere medical or other knowledge, but rather on probity, honour, a good conscience, temperance, and a heart pulsating with brotherly kindness and charity. You will soon be scattered to different parts of the earth. My earnest hope is that you may prosper, and, as your love and reverence cannot fail to turn to this old hospital as surely as the needle seeks the pole, may we hope that in these recollections a place may be found for us who have had the privilege of taking part in your professional education."

Amalgamation of the Dublin Medical Schools.

I understand that His Excellency Earl Zetland signed the necessary documents on Saturday last sanctioning the scheme of amalgamation of the College of Surgeons School with those of the Carmichael and Ledwich institutions. Advertisements have been inserted for the appointment of the following professors:—One professor of anatomy, one professor of midwifery, one of medical jurisprudence, one of medicine, one of chemistry, one of materia medica, one of zoology and botany, one of pharmacy, and one of ophthalmology. The election will take place on Wednesday, the 23rd inst.

Dr. Atkinson and Mr. Warnock, F.R.C.S.I., have been admitted members of the Royal Historical and Archæological Society of Ireland.

Dr. James Macan, J.P., died at his residence, Sharvagh, Bushmills, on the 5th inst.

Dublin, Oct. 8th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Vision Area in the Encephalon.

IN a note on the seat in the encephalon of the chromatic sense, of the luminous sense, and of the sense of forms, Dr. Veney, after several observations, arrives at the following conclusions: that the chromatic sense resides in the lowest portion of the occipital lobe, probably in the posterior part of the lingual and fusiform gyri; the luminous sense would be found higher, near the upper part of the occipital lobe, and the centre of perception of forms between the two preceding regions. The author had an opportunity of verifying his conclusions in the following case that came under his observation. A woman aged sixty years was seized with cerebral congestion, without loss of consciousness, and accompanied with vomiting. There was a distinct hemiachromatopsia, with partial preservation of the light perception and form. There were no aphasic troubles, no word blindness, no paresis or paralysis of the extremities. The ophthalmoscope revealed no lesion whatever of the optic nerve. This state remained stationary for twenty months. In March, 1888, the patient succumbed in few days to an attack of apoplexy, which produced a hemiplegia of the left side. At the autopsy an enormous hæmorrhagic focus, of recent formation, was found in the

Digitized by Google

right cerebral hemisphere; the lesion had destroyed the whole of the centrum ovale, the central ganglia, and had penetrated into the right lateral ventricle. There existed a very old lesion, a hæmorrhagic cyst, at the inferior portion of the left occipital lobe.

Resistance of Trichinæ to Cold.

At the meeting of the Academy of Sciences last week, M. Paul Gibier gave an account of his recent researches regarding the resistance to the action of cold on trichinæ contained in meats. The substances on which his researches were carried out were hams salted with a mixture of marine salt and saltpetre. The trichinæ which were found in them did not resist the action of a temperature of a few degrees under freezing point, maintained for nearly an hour. The case is different, however, when the meat is not salted, as then a low temperature of 25 degrees centigrade below zero, continued even for two hours, is insufficient to render fresh meats containing trichinæ sweet.

Sense of Taste in Criminals.

The following note reproduced in the *Journal de la Santé* may be found interesting. Dr. S. Ottolenghi, a pupil of Professor Lombroso, has studied the sense of taste in criminals compared with that of other individuals. He says that in criminals the sense of taste is manifestly weak relatively to that of ordinary individuals; there is, again, a difference less marked between occasional delinquents and those who are habitual or born delinquents. Female criminals have the sense of taste still more obtuse than men of the same category. The author concludes from these remarks that this diminution in the sense of taste in criminals depends on a defect in the cerebral cortex.

The Administration of Chloroform.

M. Dastre lately made a communication to the Société de Biologie relative to the dangers of anæsthesia by the use of chloroform, and recalled that he had always prevented these dangers in dogs by preceding the administration of the chloroform with a subcutaneous injection of atropine associated with morphia. He remarked that death which occurs during anæsthesia is often due to an irritation of the pneumogastric ganglia, which produces arrest of the heart and death by syncope. The atropomorphinic injection has the effect of preventing the production of this excitation.

Fire at the School of Medicine.

Yesterday, about twelve o'clock, a fire took place in the Amphitheatre of the School of Medicine during the meeting of the International Congress of Surgery. Considerable damage was done, as furniture and paintings of great value were burnt. The fire was traced to the over-heating of a pipe leading from a large stove placed in the cellars for warming the whole building. Fortunately the meeting had just been brought to a close, and the members were able to effect their escape. After nearly two hours the firemen succeeded in putting out the fire, just in time to save the library and the museum of anatomy. A similar accident occurred in the same place about two years ago.

Statue to M. Dumas.

The inauguration of the statue of J. B. Dumas, the celebrated chemist, will take place on Oct. 21st, at Alais, his native town, under the presidency of M. Pasteur, and in the presence of members of the Institute and several members of the Government.

An Incident at the Academy of Medicine.

At the meeting of the Academy on the 1st inst., M. Laborde refuted the statements made by MM. Cadeac and A. Meunier that the ill effects of absinthe drinking should be attributed not to absinthe but to anise, fennel, and other essences with which it is mixed. He demonstrated this by administering to guinea-pigs subcutaneous injections of the essence of anise and that of absinthe. The demonstration was interrupted by a lady visitor of anti-vivisection sympathies, who was removed from the gallery by order of the President.

Paris, Oct. 9th.

NAVAL MEDICAL SUPPLEMENTAL FUND.—At the quarterly meeting of the directors of the Fund held on the 8th inst., T. J. Haran, Esq., Inspector-General in the chair, the sum of £68 was distributed among the several applicants.

Obituary.

SIR W. TINDAL ROBERTSON, M.D. EDIN., F.R.C.P. LOND., M.P.

SIR TINDAL ROBERTSON, whose sad death took place on Sunday last, was the eldest son of the late Frederick Fowler Robertson of Bath and Anne Tindal his wife. Educated at King Edward VI.'s Grammar School, Grantham, he entered the medical profession as house-pupil to Mr. H. P. Robarts, F.R.C.P., of Great Coram-street, London; studied at University College Hospital, and matriculated, in the first class, at the University of London in July, 1846. He became L.S.A. in 1848, M.R.C.S. in 1850, was Junior Resident Medical Officer at the Middlesex Hospital in 1848-50, and Resident Surgeon at the Royal Free Hospital from 1850-51. He subsequently studied at Paris and Edinburgh, taking his M.D. degree at the latter University in 1853. In 1854 he commenced practice in Nottingham, where he held appointments on the medical staff of all the leading charities, being for nearly twenty years physician to the Nottingham General Hospital. In 1874 he was elected a Fellow of the Royal College of Physicians. In 1857, when the British Medical Association held its meeting at Nottingham, Dr. Tindal Robertson was selected to deliver the Address in Medicine, and he took as his subject, "The Rise and Progress of Sanitary Science." Again, at the meeting of the same Association in 1865 he introduced the question, "Why are sanitary measures not always followed by a reduction in mortality?" He initiated at Nottingham, with the help of many of his medical friends, a system of voluntary notification of diseases. Through his initiation, also, the Oxford local examination system was established in Nottingham, and, in conjunction with Mr. Mundella, M.P., he promoted the formation of the corps of Robin Hood Rifles, as medical officer of which he was presented to the Queen. He was instrumental in establishing the Nottingham Literary and Philosophical Society, was one of the local secretaries for the visit to Nottingham of the British Association for the Advancement of Science, and subsequently published the "Record of the Transactions" on that occasion. He was also a member of the Nottingham Town Council; he contributed to Mr. Churchill's "Photographs of Eminent Medical Men" the brief analytical notices of their works, besides many articles in reviews &c. In 1873 his eyesight began to fail, and he retired from practice, and went to reside at Brighton. In 1880 he became chairman of the Brighton Conservative Association, and from that time he took a foremost part in politics. In 1886 he was returned unopposed to Parliament for Brighton in the place of Mr. D. Smith, deceased. Sir Tindal Robertson was a member of the recent Royal Commission on the Blind, Deaf, and Dumb, &c., of which he acted as vice-chairman. At the time of his death he was a member of the Brighton Town Council, trustee of the Gardner Fund for the Blind, one of the vice-chairmen of the Home Counties Conservative Union, a member of the Grand Council of the Primrose League, and of the Council of the National Union of Conservative Associations, a J.P. for Brighton and Sussex, and, as stated above, M.P. for Brighton. He received the honour of knighthood in 1888. He married in 1855 Elizabeth Anne, daughter of Mr. John Leavers, of the Park, Nottingham, by whom he had issue, four sons, who survive him.

We are indebted to Dr. Elborough Scatliff for the following details concerning Sir Tindal Robertson's last illness:—

In May last Sir Tindal Robertson sprained his ankle as he was leaving the House of Commons, and in consequence of this accident he was a good deal confined to his room, and gave up his usual out-door exercise. He had for some time been troubled with weak digestion, and with loss of exercise his dyspeptic symptoms became greatly aggravated. He soon refused solid food and took fluid nourishment mixed with artificial digestives. Then he rapidly became hypochondriacal and despondent, so that he began to fear (in consequence of his continued abdominal discomfort) that he had some structural mischief, malignant or otherwise, producing a partial stricture of the bowel, first at one spot and then at another. On the most careful

Digitized by Google

examination no abdominal tumour could be detected, nor was there ever any evidence of obstruction. Still his mind clung tenaciously to this impression, notwithstanding that Dr. Brown-Séquard (who was at that time staying in Brighton) very kindly saw him with me on more than one occasion, and fully concurred in the opinion that I had given. Sir Tindal Robertson had been blind for some years from glaucoma, and had undergone several operations at the hands of Dr. Bell Taylor, Sir W. Bowman, and Mr. Bader. Besides this there was evidence—such as very feeble patellar tendon reflex, slight dragging of the left leg, &c.—that the spinal cord was not in a normal state. Notwithstanding all that was done for his relief, his dyspeptic trouble and depression of spirits still continued, and only last Monday week Dr. Russell Reynolds kindly came down from town on purpose to see him in consultation with me. He also carefully examined the abdomen and corroborated the opinion given. On Saturday last Sir Tindal Robertson went to bed at the usual time apparently in slightly better spirits than of late (perhaps due to a conversation we had had together in the morning). The rest of the tragic story is already well known, so it need not be repeated. At the necropsy about forty-eight hours after death (the abdominal organs only being examined) nothing abnormal was found in the intestine or abdominal cavity, but the walls of the bowel were very thin and the ascending colon slightly dilated.

Dr. Russell Reynolds writes to us as follows:—

On my return from abroad I found a letter from Dr. Scatliff, asking me, at Sir Tindal Robertson's request, for advice upon his case. On the next day (Sept. 22nd) I wrote in reply. The troubles laid before me were mainly those of the abdominal region, with regard to which Sir Tindal had become most anxious, being under the impression that he was suffering from organic disease of the intestine. It had also been observed by his friends and by Dr. Scatliff that his walk had become somewhat feeble, and that he drooped a little on one side. I made in my answer some suggestions as to medicines and board, and I heard, after five days, that he was slightly better, but still very anxious and depressed about himself. He suggested coming to London mainly with the idea of being under my care; but by letter, written on the 27th to Dr. Scatliff, I strongly recommended him to remain in the better atmosphere of Brighton, where he was surrounded by the comforts of his home, and said that, as he was an old college friend, I would again gladly come down and see him before any change was made. On Monday, Sept. 30th, I saw him in consultation with Dr. Scatliff, and we made a most careful examination of him. His abdominal troubles had diminished, but he was still very anxious about them and himself, and complained of the recurrence of distressing sensations over the whole abdomen, with frequent and great distension. At the time of my seeing him the abdomen was so flaccid that a very thorough examination was possible, as a result of which no evidence whatever could be found of any organic disease. This decision was confirmed by the post-mortem examination. He had been taking a carefully arranged diet, and was very solicitous with regard to the kind and the amount of food that would be best for him. He was aware that the patellar reflexes were almost abolished, but I do not think that he knew his walk to be slightly halting on the left side. He was anxious about the condition of his spine; but not so much so as with regard to the abdominal trouble. All the elements of his case, including those which might possibly lead to its sad termination, were fully and carefully considered by Dr. Scatliff and myself, and the result of our consultation was as fully and carefully communicated to his family. Weighing the probabilities of the future, it was to my mind a hopeful sign that Sir Tindal's anxiety appeared mainly about his physical health; that he was most anxious to do everything in his power to get better; that he spoke, after hearing my judgment on his abdominal condition, quite hopefully about himself, and that he never to me made the smallest allusion as to anxiety with regard to himself on other grounds. On the evening of the day that I saw him he dictated a letter to me asking me three questions, each of which had reference to his food or medicines. I entertained and expressed a fair hope and belief that my old friend would again, as he had done before, surmount his terrible depression and distress; but, unhappily, one of those sudden "impulses" occurred which, through physical weakness, he was unable to resist.

PROTHEROE SMITH, M.D. ABER., M.R.C.P. LOND., M.R.C.S. ENG.

DR. PROTHEROE SMITH was born at Bideford, North Devon, in 1809. His father, Dr. William Smith, was a medical practitioner in the same town. At the age of seventeen Protheroe Smith was apprenticed to his father. Having made that experience, he migrated to St. Bartholomew's Hospital, and during his student days resided with Kiernan, the anatomist. In 1833 Mr. Protheroe Smith took the M.R.C.S. Eng., and in 1846 the M.R.C.P. of London, having previously (1844) graduated M.D. of King's College, Aberdeen. He became co-lecturer with Dr. Rigby, at St. Bartholomew's Hospital, upon the subjects of Midwifery and Diseases of Women. In his early days Dr. Protheroe Smith wrote many reviews for our columns. He founded in 1842 the Hospital for Women in Red Lion-square. That institution was later on removed to Soho-square, where it still is, and was the first hospital founded for the benefit of women alone. Dr. Protheroe Smith practised first in John-street, Bedford-row; but in 1847 he removed to Park-street, Park-lane, where he lived till nearly the time of his death.

It is claimed for Dr. Smith that he was the first in England to give anæsthetics in midwifery. Until Simpson sent him chloroform from Edinburgh he used ether in cases of labour. In 1842 he performed his first ovariotomy, so that he was one of the earliest of our operators in that connexion. He performed the operation without the help of an anæsthetic, and the patient is probably alive now, and was certainly living a year or two ago. Dr. Protheroe Smith did not contribute much to the literature of his profession. He turned his attention chiefly to the inventing of instruments connected with his own branch of practice, and to the devising of improvements in them. The list is quite a long one: a chloroform inhaler exhibited at the Royal Medical and Chirurgical Society in 1848; an aspirator or exploring needle trocar, shown at the meeting of the British Medical Association at Dublin, 1867; specula of various kinds. These, and many other instruments, have been associated with Dr. Protheroe Smith's name. He and Sir J. Y. Simpson seem, about the same time, to have planned a uterine sound. The former used the sound, in the first instance, as a measurer of the uterus, the latter employed it as a tactile instrument.

As has been already said, Dr. Protheroe Smith wrote but little, his chief contributions to medical literature being a pamphlet on Cholera, and another on Flexures of the Uterus. He was a man of marked religious views, of the Evangelical school, and made those views prominent in every relationship of his life. In 1887 Dr. Protheroe Smith was seized with great pain in the sigmoid flexure of the colon. It was feared that he was the victim of malignant disease in that region of the bowel; but all those symptoms passed away. In August of this year he suddenly became comatose, but without any clearly defined evidences of paralysis. From that time he gradually sank, and died on Sept. 29th last. When the body was examined post mortem, there was not found any conclusive evidence of the cause of death. The arteries were markedly atheromatous, and the liver afforded an exceptionally well-defined example of the cirrhotic condition, although all his life Dr. Protheroe Smith had been a very abstemious man. The intestines, both in the neighbourhood of the sigmoid flexure and elsewhere, were found to have been healthy. The head was not opened after death.

JAMES MACAN, M.D. EDIN., J.P.

WE regret to have to announce the death of Dr. James Macan, which took place at his residence, Bushmills, co. Antrim, on Saturday, Oct. 7th, after a short illness. Between two and three weeks ago he complained of feeling unwell, but struggled against the symptoms until he was compelled to take to his bed, when symptoms of typhoid fever developed, from which he died. After graduating in Edinburgh in 1852, Dr. Macan began practice in his native town, Bushmills, thirty-five years ago, and by his ability, attention, and kindly disposition rapidly acquired a very large country practice, and in recent years all over the

Digitized by Google

north of Antrim he was called in by his medical *confrères* as a consultant in whom both they and the public had very great confidence. At the time of his death he was dispensary doctor of the Bushmills district, and consulting sanitary officer for the Coleraine Union. He was also medical officer of the constabulary and the coastguard, and a magistrate for the county of Antrim. Dr. Macan's death has caused widespread sorrow throughout the north of Antrim, where he was a very great favourite, as well as in Belfast, where he had many warm and attached friends.

Medical News.

EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGES OF PHYSICIANS AND SURGEONS.—The following gentlemen passed the Second Examination of the Board in Anatomy and Physiology at a meeting of the Examiners on the 7th inst.:—

G. B. Hillman, H. A. Phillips, J. E. Gains, and E. S. Perkins, students of Yorkshire College, Leeds; P. Withers and Joseph Green, of Owens College, Manchester; H. W. S. Williams, of University College, Liverpool; W. M. Smith, of Cambridge University; Gerald Grace and H. B. Wilson, of Bristol School of Medicine; J. G. Warren, of Trinity School of Physics, Dublin; E. McN. Woods, of Queen's College, Belfast; C. M. Macknight, of Melbourne University; and J. H. Day, of Charing-cross Hospital.

Anatomy only.—A. A. Smith, of Yorkshire College, Leeds; E. Wooldridge, of Queen's College, Birmingham; F. Spurr, of Sheffield Medical School; H. F. Cook, of University College, Liverpool; G. A. Peake, of Bristol School of Medicine; M. P. A. Lesur, of St. Bartholomew's Hospital; and G. H. Jones, of Middlesex Hospital.

Physiology only.—J. G. Rowell and J. H. Staniland, of Yorkshire College, Leeds; L. F. Houghton, of Sheffield and St. Mary's Hospital; H. M. Joynson and E. Smallwood, of University College, Liverpool; Lancelot Kilroy and Edmund Johnstone, of Owens College, Manchester; P. H. Edwards and J. B. Garman, of Queen's College, Birmingham; C. E. Oakeley, of St. George's Hospital; C. G. Mathews, of St. Bartholomew's Hospital; and E. C. Hope, of Melbourne and Mr. Cooke's School of Anatomy and Physiology.

Passed on the 8th inst.:—

Anatomy and Physiology.—J. S. E. Selby, of St. Bartholomew's Hospital; A. J. Harrington, University of Toronto; E. M. Iliewiez, of St. Mary's Hospital.

Anatomy only.—H. C. W. Clarke, of Owens College, Manchester; J. E. Ransford, of Bristol School of Medicine; T. W. Hall, of Carmichael College, Dublin; J. S. Tabb, of Charing-cross Hospital; C. M. Fleury, W. B. Donnelly, and S. Croneen, of Guy's Hospital; F. W. Lewis, of St. Mary's Hospital; G. W. Robertson, of London and Edinburgh University; H. C. Barnes and J. H. Bicket, of London Hospital; C. K. Mosuley, G. A. T. Fox, and Fielding Clarke, of St. Bartholomew's Hospital; N. E. E. McTaggart, of St. Bartholomew's and Mr. Cooke's School of Anatomy and Physiology; R. D. Waghorn, of Westminster Hospital; A. D. Bensusan, of St. Thomas's Hospital; E. J. T. Jones, J. H. F. Way, of St. Thomas's and Mr. Cooke's School of Anatomy and Physiology; W. S. Langworthy, C. H. Chapman, and F. L. Underwood, of University College.

Physiology only.—R. W. Brinacombe, of Queen's College, Birmingham; L. J. G. Carré and J. T. R. Wylie, of St. George's Hospital; G. H. Norris, H. Arathoon, Frank Scorer, Theodore Shütte, and C. S. Palmer, of St. Bartholomew's Hospital; J. P. Jones, of London Hospital; Thomas Ager, of London Hospital and Mr. Cooke's School of Anatomy and Physiology; P. W. Campbell, E. H. Willock, Arthur Haines, and F. Pershouse, of St. Thomas's Hospital; E. E. B. Landon, of Guy's Hospital; T. H. E. Meggs, of Westminster Hospital; G. W. B. Waters, of University College; H. A. Kynsey, of University College and Mr. Cooke's School of Anatomy and Physiology; A. W. C. Herbert and S. W. Sweetnam, of St. Mary's Hospital.

Passed on the 9th inst.:—

Anatomy and Physiology.—John Miller, W. J. Ansorge, E. J. Hawkins, of St. Bartholomew's Hospital; John Griffiths, of St. Bartholomew's and Edinburgh; F. C. Stearn, of Guy's Hospital; G. F. Morley, of St. George's Hospital; E. B. Pickthorn, of St. George's and Mr. Cooke's School of Anatomy and Physiology; J. F. Stockwell, of St. Mary's Hospital; C. E. Reinhardt, of London Hospital; Albert Paling and David Phillips, of Middlesex Hospital; and P. W. H. McKeown and J. T. Campbell, of Toronto University.

Anatomy only.—S. B. Axford, of Charing-cross Hospital; E. E. W. Roe, of Guy's; G. L. Hanwell, of St. Thomas's and Mr. Cooke's School of Anatomy and Physiology; V. B. Jepson and J. H. P. Vivian, of St. Thomas's Hospital; and C. A. N. Knox, of Dublin University and St. Thomas's Hospital.

Physiology only.—J. P. Grieves, of St. Mary's Hospital; L. P. Tomlinson, of St. George's Hospital; J. D. Hessey, of Middlesex Hospital; and J. D. Rawlings and T. St. Stephens, of St. Bartholomew's Hospital.

ROYAL UNIVERSITY OF IRELAND.—The following candidates have passed the Third Examination in Medicine of this University:—

Upper Pass Division.—John A. Adams, G. H. Frost, Andrew Fullerton, Thomas W. Fullerton, K. Maguire, James B. Moore, Hamilton Morton.

Passed.—Joseph H. Anderson, David Bennett, Christopher Bunton, James F. Carroll, Anna L. Church, Michael Coughlan, Frederick Craig, Robert Creighton, Patrick Crowley, William Duff, Maurice Fitzgerald, Robert Fraser, Patrick Goold, Robt. J. Gordon, Edward F. Hanrahan, Henry Harley, Hugh T. Heron, Daniel Hill, Thomas Jackson, John Jamison, Paul Jennings, James Keegan, Joseph F. Kelly, Robert Lyons, Michael McCann, Robert McDowell, John McGennis, James McLaren, William Moody, Henry J. Moore, Jas. Morrow, Timothy Murphy, William O'Gorman, Henry O'Reilly, Joseph A. Sullivan, Alexander Robb, William L. Storey, Hugh Stranaghan, James Thompson, James Ross Thomson, Arthur J. Tonkin, Robert Wagner, George S. Walker, John T. Wallace, Thos. B. P. Wilkinson.

SOCIETY OF APOTHECARIES OF LONDON.—The following candidates, having passed the qualifying examination in Medicine, Surgery, and Midwifery, have received certificates entitling them to practise in the same, and have been admitted as Licentiates of the Society on Sept. 12th:—

Slater, Howard, University College.

On the 18th:—

Dalton, James Henry Chesshyre, Cambridge University.
Stone, Emma Constance, Women's Med. Coll. Toronto.
Molson, James Elsdale, Middlesex Hospital.
Smyth, John, Queen's College, Belfast.
Fowler, Frank, St. Thomas's Hospital.

On the 19th:—

Crompton, Alfred, St. Bartholomew's Hospital.
Hicks, John Abernethy, Westminster Hospital.
Kempthorne, Albert Edward, London.
Mitchell, Walter, Sheffield Infirmary.
Rouse, Eusebius Rouse, St. Bartholomew's Hospital.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—Surgeon-Major A. H. C. Dane, having passed the necessary examination, has been granted the Diploma in Public Health of the College.

OPHTHALMIC HOSPITAL FOR HANWELL.—The Local Government Board has sanctioned the borrowing of £24,000 for the purpose of enabling the managers of the Central London School District to erect a new hospital at Hanwell, where ophthalmia has for some time past been prevailing.

CHARING-CROSS HOSPITAL STUDENTS' DINNER.—The annual dinner of past and present students will take place at the Holborn Restaurant on Friday, Oct. 18th, at 6.30 for 7, Surgeon Whitehead, F.R.C.S., in the chair. Tickets can be obtained by applying to A. H. Walker, at the hospital.

CROYDON ROOKERIES.—In order to widen the High-street of Croydon and at the same time abolish a number of tenements described as rookeries, the Town Council have decided to apply to Parliament for compulsory powers to purchase the latter property. It is estimated that the scheme will cost at least £100,000.

LITERARY INTELLIGENCE. — The compendious treatise on Medicine by Dr. H. Eichhorst of Zurich, which has gone through three or four editions, has been translated into French (four vols.; Paris, Steinheil). The work of translation has been shared by a considerable number of young physicians connected with the Paris hospitals.

THE "LION" TRAINING SHIP IN QUARANTINE.—Admiral Sir William Dowell, Naval Commander-in-Chief at Devonport, has directed this ship to be placed in quarantine. An epidemic of scarlet fever and scarlatina has prevailed during the past few weeks in the towns of Plymouth, Stonehouse, and Devonport, and many cases have been sent from the *Lion* to the hospital.

RABIES.—The number of dogs in England officially reported during the week ending Sept. 28th as afflicted with rabies was eight, against six in the previous week; of these six were killed and two died. The distribution was as follows:—Middlesex (excluding London), three; Surrey (excluding London), two; and Chester, Hertford, and York (West Riding), one each. No cases were reported from London proper.

SUPPOSED SUICIDE OF A PHYSICIAN.—Dr. Jeremiah Wase of Huntspill, Somerset, was found dead in his bedroom last Thursday morning, having died apparently from poisoning. He had written a few lines on some blotting-paper, to the effect that he could not stand the strain any longer. Dr. Wase was the principal witness in a child-murder case to be investigated by the bench of magistrates at Bridgwater on the 10th inst., he having made a post-mortem examination of the body of the infant, and it is supposed that the case had caused him considerable worry.

DARWEN INFECTIOUS DISEASES HOSPITAL.—The formal opening of the new Infectious Diseases Hospital for Darwen took place on the 2nd inst., the members of the Health Committee, the medical staff, and other gentlemen being present. The hospital, which cost £4700, is composed of three separate one-storey buildings; one for small-pox patients, another for patients suffering from fever, and the third to be used as a mortuary.

THE LATE DR. GUTHRIE.—A handsome marble cross has been erected at the grave of the late Dr. Guthrie in the churchyard at Esher. The monument, which cost £54 15*s.*, was erected out of the contributions of, and as a "memorial of loving regard from, 132 patients and friends." A sum of £58 15*s.*, the balance of the amount subscribed, will be applied for the benefit and welfare of the deceased's children.

GRIMSBY AND DISTRICT HOSPITAL.—The annual general meeting of this institution was held on the 7th inst., the Earl of Yarborough presiding. The report, which was adopted, showed that whilst the average yearly expenditure was £1500, the subscriptions only amounted to £550. The chairman, in alluding to the smallness of the subscriptions, said that if the 70,000 population of Grimsby and district only contributed 6*d.* per head the amount would be ample.

NEW MILITARY HOSPITAL IN MADRID.—The military authorities in Madrid are actually beginning to erect a much-needed military hospital. The plans have been prepared by a military engineer, Capt. D. Manuel Cano, and, according to *El Siglo Médico*, leave nothing to be desired on the score of situation or hygienic arrangements, thus presenting a striking contrast to the low, ill-ventilated, insanitary building, the wards of which now form the clinic of the central university.

ST. JOHN AMBULANCE ASSOCIATION, BIRKENHEAD. Surgeon-Major Hutton presided over a large and distinguished gathering at the Town Hall, Birkenhead, on the 1st inst., on the occasion of the distribution of 140 certificates gained by students attending the several St. John Ambulance classes in Birkenhead and Rock Ferry. Surgeon-Major Hutton, in the course of his remarks, said the past year had been most successful in the establishment of classes in Birkenhead, both in first aid and in nursing. The police force of the borough had especially been most effective in obtaining certificates.

PROVINCIAL SUNDAY AND SATURDAY HOSPITAL COLLECTIONS.—At Eckington the recent Hospital Sunday collection amounted to £35 11*s.*—The first Hospital Sunday collection at Wallingford on the 22nd ult. realised £21 18*s.* 1*d.*—A similar collection at Callington on the 29th ult. produced £5 15*s.*—The Hospital Saturday recent collection at Exeter amounted to £21.—The eighth annual Hospital Sunday demonstration of the Middlesbrough Trades' Council, on behalf of the medical charities of the town—the North Riding Infirmary and the North Ormesby Cottage Hospital—realised £26 10*s.* 10*d.*

BEQUESTS AND DONATIONS TO HOSPITALS.—The Cumberland Rugby Football Union have lately made the following donations—viz.: Whitehaven Infirmary, £12; Workington Infirmary, £8; Cumberland Infirmary, £5; Silloth Convalescent Institution, £5; Carlisle Dispensary, £4; and Cockermouth Dispensary, £2; total, £36.—The treasurer of the Bootle Borough Hospital has received £500, being the second moiety of a legacy of £1000 from the late Mr. John Bacon.—The committee of the City Orthopædic Hospital, Hatton-garden, has received from the trustees of the late Mrs. Law French £200 in aid of the extension fund.—The secretary of the Swansea Hospital has received £30, contributed by workmen at the Elba Steel Works.—The late Mr. W. Billings of Leicester has, by his will, bequeathed £100 to the local infirmary.—The Court of Common Council, London, has granted a donation of £210 to Charing-cross Hospital and £210 to the City of London Hospital for Diseases of the Chest.—The late Alderman George, of Leeds, has bequeathed £10,000 to the General Infirmary, Leeds.—Mr. Greswell Williams has given £200 to the funds of the Worcester Dispensary and Provident Medical Institution.—The late Mr. Daniel Procter, of Brook-villa, Whalley Range, Manchester, has bequeathed £1000 to the Manchester Royal Infirmary, £1000 to the Manchester Clinical Hospital, £1000 to the Children's Hospital at Pendlebury, and £2000 to St. Mary's Hospital, Manchester.—The bazaar recently held in aid of the funds of the Bingley Cottage Hospital, including £300 received in subscriptions towards the Bazaar Fund, has produced, net, £1500.—Lady Forster has left £100 each to the Adelaide Hospital, City of Dublin Hospital, and the Orthopædic Hospital, Dublin.—Mr. John Rawdon Berwick, late of Coolfadda House, co. Cork, has bequeathed £300 to the Hospital for Incurables, £300 to the Home for Protestant Incurables, Cork, £300 to the Cork (South) Charitable Infirmary, £300 to St. Vincent's Hospital, £300 to the City of Dublin Hospital, £300 to the Deaf and Dumb Institution, Cabra, £300 to the Stewart Institution for Imbeciles, £300 to the Rotunda Lying-in Hospital, £300 to Sir P. Dun's Hospital, £300 to the Cork-street Fever Hospital, £200 to the Cork Asylum for the Blind, £300 to the Mater Miscricordiæ Hospital, £300 to the Meath Hospital, £300 to Mercer's Hospital, and £300 to the Molyneux Asylum for the Blind.

THE SANITARY INSPECTORS' ASSOCIATION.—The sixth annual general meeting of the Association of Public Sanitary Inspectors of Great Britain was held on the 5th inst., at the Westminster Town Hall, Mr. Hugh Alexander presiding. The report expressed disappointment at the limitation of the compulsory operation of the Infectious Diseases Notification Act to the metropolis, and avowed an intention on the part of the council to use every opportunity which might present itself to amend the Act. It was decided to accept an invitation to hold the next annual provisional meeting at Leamington.

THE BOMBAY NATIVE DISPENSARY.—The third biennial report of the Bombay Native Dispensary shows that during the years 1887–1888 the total number of patients treated was 153,456, or 4676 more than during the preceding two years. Of those treated, 60,952 were Hindoos, 59,660 Parsees, 21,714 Mussulmans, 5048 Christians, and 6082 of "other castes." The report adds that the most healthy season was from November to February, and the most sickly period from August to October, when the severe heat, after the close of the rains, dries the cesspools and low swampy places, producing malarious fevers and their accompaniments.

WEST KENT MEDICO-CHIRURGICAL SOCIETY.—The first meeting of the thirty-fourth session (1889-90) was held at the Royal Kent Dispensary, Greenwich-road, on Oct. 4th, at 8 o'clock precisely, when the following gentlemen were elected office-bearers for the ensuing year:—President: Mr. Thomas Moore. Vice-Presidents: Mr. J. Poland and Dr. John McGavin. Council: Mr. A. Stewart Brown, Dr. Clarke, Mr. Peter Cooper, Mr. A. Lloyd Jones, Dr. Nicholson, Mr. Charles Parkes, and Dr. George Newton Pitt. Treasurer: Dr. Prior Purvis. Secretary: Mr. H. W. Roberts. Librarian: Dr. Ernest Clarke.

A HOSPITAL FOR KESWICK.—The trustees of the Fitz Park, Keswick, have received an offer from Mr. Henry Hewetson, of Tunbridge Wells, to transfer to them, under certain conditions and for certain purposes, the small farm of Monks' Hall as an addition to the trust already existing. On this land, which adjoins Fitz Park and comprises fourteen acres of land, Mr. Hewetson offers to build, furnish, and maintain a cottage hospital for the benefit of the poorer classes residing in and around the district of Keswick, and proposes to pay over £300 a year during his life as the income for the year, and make provision for a similar yearly payment after his death. This generous offer has been accepted.

EYE AND EAR HOSPITAL, BIRKENHEAD.—The annual report of this hospital just issued shows that there has been a satisfactory increase in the usefulness of the institution. The arrangements reported by the committee last year with regard to dispensing their own medicines had been a success. The saving thus effected over the former system was larger than anticipated. The patients at the dispensary during the year numbered 1212, of whom 120 were admitted free. The total attendance was 7121. The number of in-patients was 56; the beds (six) were occupied 1276 days, giving an average time for a patient of nearly twenty-three days. The balance-sheet showed a small balance in hand. The outstanding accounts amounted to £122 7*s.* 11*d.*

A COTTAGE HOSPITAL FOR SIDMOUTH.—A communication from an anonymous benefactor has been received by the committee appointed to promote the establishment of a cottage hospital for Sidmouth, offering a donation of £500 towards the object in view. The offer seems to have had the effect of stimulating other well-wishers to the town to the exercise of liberality in the same direction, so that the scheme appears likely to be realised.

ROYAL COMMISSION ON VACCINATION.—The Royal Commission on Vaccination resumed their sittings on Wednesday at Richmond-terrace, Whitehall. There were present Lord Herschell (Chairman), Sir James Paget, Bart., Sir Charles Dalrymple, M.P., Sir W. Guyer Hunter, K.C.M.G., M.P., Sir E. H. Galsworthy, Mr. William Scovell Savory, F.R.S., Mr. Charles Bradlaugh, M.P., Dr. John Syer Bristowe, Dr. William Job Collins, Professor Michael Foster, M.D., Mr. Jonathan Hutchinson, Mr. J. Allanson Picton, M.P., Mr. F. Meadows White, Q.C., and Mr. Bret Ince, secretary. Surgeon-General J. Pinkerton and Dr. Arthur F. Hopkirk were examined.

OPEN SPACES.—There was a long discussion at the meeting of the Newington Vestry on Wednesday night, consequent upon a recommendation from the General Purposes Committee that the consideration of the memorial from the Brockwell-park Committee asking the vestry's assistance in acquiring the park as an open space for the public, by making a grant towards the purchase money, be deferred until the vestry had statutory power to make a contribution. The chairman (the Rev. G. T. Palmer) moved as an amendment that a contribution of £5000 be made, and after a long debate that proposal was adopted.

ASSOCIATION OF CERTIFYING SURGEONS.—A general meeting of the Association of Certifying Surgeons was held in the Victoria Hotel, Manchester, on Wednesday. The meeting, which was a very representative one, was presided over by Mr. Walmsley, Salford, president, supported by Dr. Arlidge, Stoke-on-Trent, vice-president. The president and treasurer submitted reports, which show the Association to be in a flourishing condition both numerically and financially, and well able to carry out any measures necessary for the furtherance of its objects. Several resolutions relating to the sanitary condition of factories &c. were discussed and adopted.

BATH EYE INFIRMARY. — A special general meeting of the governors and subscribers of this institution was held at the Infirmary, No. 1, Belvedere, on the 30th ult., to consider the revised rules framed for the management of the Infirmary, which had been removed to more commodious premises. After the new rules had been adopted, a statement was made as to the financial position of the Infirmary, the cost of purchase and moving from the old house to the present building being about £1550. The patients had increased from 700 to 1200 in a comparatively short space of time, and the hope was expressed that additional support would be accorded to the Infirmary.

PRESENTATIONS.—Dr. J. Wilton of Sutton, Surrey, has been presented by his friends and patients, on his retiring from the profession and leaving the town after a long and honourable connexion therewith, with a handsome testimonial consisting of four massive silver candlesticks, a piece of plate, and an illuminated address on vellum.—On the 7th inst., Dr. W. H. Dawson, consulting physician to the Malvern Rural Hospital, was presented by the patients of the institution and friends with a purse containing £102, a clock, and two bronze statuettes, and a parchment roll with the names of 170 subscribers. Dr. Dawson has gratuitously served the hospital for the past twenty-one years, and was still connected with it as consulting physician.—At Sheffield on Friday, Oct. 4th, Mr. Simeon Snell, M.R.C.S. Eng., L.R.C.P. Lond., was entertained at a complimentary dinner given by some thirty of his medical *confrères* in Sheffield, and was presented with a handsome silver tray, with an appropriate inscription and an illuminated address, on behalf of eighty-one members of the Sheffield Medico-Chirurgical Society, as a mark of their appreciation of the successful and admirable manner in which he had for thirteen years fulfilled the duties of honorary secretary to that society, and which post he resigned at the close of last session.

SCHOLARSHIPS. — *London Hospital:* Mr. C. P. Harris has obtained the first Entrance Science Scholarship of £60, and Mr. G. H. Cowen the second of £40. Mr. C. O. Williams has obtained the first Buxton Scholarship of £30, and Mr. E. J. G. Tucker the second of £20.—*Charing-cross Hospital:* Mr. Thomas Sandells has obtained the first Entrance Scholarship of one hundred guineas, and Mr. Frederick A. L. Hammond the second of fifty guineas. Mr. A. G. Harvey, of St. John's College, Cambridge, has been awarded the Universities Scholarship of fifty guineas.

COMPLIMENT TO A PHYSICIAN.—A number of medical men and other friends met together at the Royal Hotel, Swansea, last week, on the occasion of giving a farewell dinner to Mr. John Farrant Fry, L.R.C.P. Lond., M.R.C.S. Eng., who is removing from Swansea, where he has practised for fourteen years, to Shepton Mallet, Somersetshire, for the benefit of the health of himself and family. Speeches were made lauding Mr. Fry's past services to Swansea, and notably to Swansea Hospital, with which he had been connected for the past eleven years, and wishing him every prosperity in his new home. Mr. Fry replied in appropriate terms, and after a musical interlude, the meeting, which was unanimous and enthusiastic, concluded by a general handshaking with Mr. Fry in token of farewell.

MEDICO-CHIRURGICAL SOCIETY OF GLASGOW.—At the first meeting for the session held on the evening of the 4th inst. the following gentlemen were elected office-bearers for session 1889-90:—President: Dr. William Macewen. *Section of Medicine:*—Vice-President, Dr. J. Wallace Anderson; Council, Dr. Hugh Thomson and Dr. W. G. Dun; Secretary, Dr. Geo. S. Middleton. *Section of Surgery:*—Vice-President, Dr. David W. Knox; Council, Dr. W. J. Fleming and Dr. J. C. Renton; Secretary, Dr. John Barlow. *Section of Pathology:*—Vice-President, Dr. W. T. Gairdner; Council, Dr. H. Rutherford, and Dr. Joseph Coats; Secretary, Dr. T. Kennedy Dalziel. *Section of Obstetrics:*—Vice-President, Dr. W. L. Reid; Council, Dr. M. Cameron, and Dr. Samuel Sloan; Secretary, Dr. Lawrence Oliphant; Treasurer, Dr. Henry E. Clark; General Secretary, Dr. Walker Downie.

THE AFTER-CARE ASSOCIATION. — The annual general meeting of the members and friends of this Association was held on July 4th at the residence of the Earl of Meath (President), who occupied the chair. There are about 30,000 women of various callings and conditions of life in lunatic asylums in England and Wales, and of these a large number are discharged in the course of the year recovered. Many of these are entirely friendless, but desirous, and often very capable, of earning their own living. The chief objects of this Association are to facilitate the readmission of poor and friendless female convalescents from lunatic asylums into social life, by obtaining for them, when needful, change of air and scene, by grants of money and clothing, and by assisting them to obtain suitable employment. The report, which was adopted, states that funds are urgently needed to carry on and extend the work of the Association, and the Secretary, Mr. H. Thornhill Roxby, "Arden Lea," The Drive, Walthamstow, Essex, will thankfully receive contributions.

SALFORD WORKING MEN'S SANITARY ASSOCIATION.—At the first general meeting of this Association, held recently in Salford, the secretary, Mr. Alfred Settle, gave an account of the work done by the Association since the first appointment of the committee four months ago. They had received numerous complaints from tenants belonging to the working classes as to the insanitary condition of their abodes, and the Association had brought the matters complained of under the notice of the Health Committee, and for the most part they had been attended to with promptness, and the officials had shown great courtesy. Through the action of this Association the Corporation and the property owners had been wakened up, and the latter, who had hitherto neglected their duty, were now doing something to mitigate the evils of the people's surroundings. Several speakers followed, and drew attention to the rookeries and slums which abounded in Salford, and which were unfit for habitation. They urged that the Association should leave nothing undone to compel the town councillors to do their duty in the matter of proper sanitation for the town.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement.

BRADFORD INFIRMARY AND DISPENSARY.—House Physician. Salary £100 per annum with board.

BURTON-ON-TRENT INFIRMARY.—House Surgeon. Salary £130 per annum with a prospect of increase, and rooms in the infirmary free, also coals and gas.

CLAYTON HOSPITAL AND GENERAL DISPENSARY, Wakefield.—House Surgeon. Salary £120 per annum, with residence at the hospital, attendance, coals and gas.

DORSET COUNTY ASYLUM.—Assistant Medical Officer. Salary £120 per annum, with board and residence.

FLINTSHIRE DISPENSARY, Bagillt-street, Holywell.—House Surgeon. Salary £100 per annum, with furnished house, rent and taxes free, with a prospect of £20 increase after twelve months; also coal, light, water, and cleaning, or in lieu thereof the sum of £20 per annum.

GENERAL HOSPITAL, Birmingham.—Assistant Physician, for three years. Honorarium £100 per annum.

GENERAL INFIRMARY AT LEEDS.—Resident Obstetric Officer. House Physician. House Surgeon. These appointments for twelve months.

HANTS COUNTY ASYLUM, Knowle, Fareham.—Junior Assistant Medical Officer. Salary £100 per annum, with furnished apartments, board, washing, and attendance.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, London, W.C.—Resident Medical Officer as House Surgeon, for one year. Salary £50 per annum, with board and residence in the hospital.

HOSPITAL FOR WOMEN.—London School of Gynæcology, Soho-square, W.—Clinical Assistants in both Out-patient and In-patient Departments.

JOINT COUNTIES ASYLUM, Carmarthen.—Junior Assistant Medical Officer. Salary £100 per annum, with board, lodging, washing, and attendance.

LANCASHIRE COUNTY ASYLUM, Rainhill, near Liverpool.—Assistant Medical Officer. Salary commencing at £105 per annum, with furnished apartments, board, attendance, and washing.

LIVERPOOL DISPENSARY, 34, Moorfields, Liverpool.—Two Assistant Surgeons. Salary £80 per annum each, together with apartments, board, and attendance.

LIVERPOOL INFIRMARY FOR CHILDREN, Myrtle-street.—House Surgeon. Salary £85 per annum, with board and lodging.

LIVERPOOL ROYAL INFIRMARY.—Honorary Surgeon.

NORTH-WEST LONDON HOSPITAL, Kentish-town-road.—Senior Resident Medical Officer. In the event of the Assistant Medical Officer being appointed to the senior post, candidates should state if they will take the Junior appointment.

OWENS COLLEGE, Manchester.—Junior Demonstrator in Physiology. Salary £100 per annum.

PARISH OF EDAY, Orkney, to Inspector of Poor.—Resident Medical Officer. Salary £70 a year and practice.

PUBLIC DISPENSARY, 59, Stanhope-street, Clare-market.—Resident Medical Officer. Salary £105 per annum, with furnished apartments, coals, and gas.

SHEFFIELD GENERAL INFIRMARY.—House Surgeon. Salary £120 per annum, with board, lodging, and washing, with a prospective advance of £10 per year for the second and third years. Also Assistant House Surgeon. Salary £80 per annum, with board, lodging, and washing. These appointments to continue for three years only.

ST. MARY'S HOSPITAL, Quay-street, Manchester.—House Surgeon and Resident Obstetric Assistant Surgeon Salary £120 per annum, with board and residence.

THE COUNTIES ASYLUM, Carlisle.—Junior Assistant Medical Officer. Salary £80 with board.

WOLVERHAMPON AND STAFFORDSHIRE GENERAL HOSPITAL, Wolverhampton.—House Surgeon. Salary £100 a year, with board, lodging, and washing.

Births, Marriages, and Deaths.

BIRTHS.

BOTTRELL.—On Aug. 25th, at Villa Rica, Paraguay, the wife of J. F. H. Bottrell, M.R.C.S.E., of a daughter.

BOUCHER.—On Oct. 3rd, the wife of Arthur H. Boucher, M.D., Hertford, of a son.

GEOGHEGAN.—On Oct. 4th, at Shooter's-hill-road, Blackheath, the wife of Surgeon Alfred Geoghegan, Medical Staff, of a daughter.

MARTIN.—On Oct. 7th, at 10, Mansfield-street, Cavendish-square, W., the wife of Sidney Martin, M.D.Lond., M.R.C.P., of a daughter.

MCCONNELL.—On Sept. 13th, at Wood-street, Calcutta, the wife of Surgeon-Major J. F. P. McConnell, M.D., F.R.C.P., of a daughter.

STEVENS.—On Oct. 4th, at High-street, Stoke Newington, N., the wife of A. Felix Stevens, M.D., of a daughter.

MARRIAGES.

BENCRAFT—PERKINS.—On Oct. 8th, at Highfield Church, Southampton Henry William Russell Bencraft, M.R.C.S., of Anglesea-place, Southampton, to Kate Margaret, second daughter of Walter Perkins, of Postwood House, Southampton.

CARTER—RIACH.—On Sept. 21st, by licence, at St. Peter's, Streatham-hill, William J. B. Carter, M.R.C.S. Eng., L.R.C.P. Lond., to Gwendolyne Brae Riach.

COCKBURN—LAW.—On Oct. 1st, at Christ Church, Lancaster-gate, Surgeon-General R. Cockburn, Bengal Army (retired), to Mary Louisa, widow of the late Lieut.-Col. E. A. Law, Royal Dublin Fusiliers, and daughter of the late C. A. Anstey.

COPELAND—HUMPHRIES.—On Oct. 8th, at Rathmichael Church, Shankill, co. Dublin, W. H. Lawrence Copeland, B.A., M.B.Cantab., of Philbeach-gardens, Earl's-court, S.W., only son of the late W. H. Copeland, J.P., Anglesea, to Zoe Jane, eldest daughter of the late Walter Humphries, M.D., Mona, Shankill.

DAVY—CUTCLIFFE.—On Oct. 8th, at Witheridge, Richard Davy, Surgeon to the Westminster Hospital, to Edith, third surviving daughter of George Cutcliffe, Esq., J.P., of Coombe House, Witheridge, North Devon.

FERGUSON—WATSON.—On Oct. 9th, at Charlotte-square, Edinburgh, by the Rev. Charles Watson, D.D., Free Church, Largs, uncle of the bride, James Haig Ferguson, M.B., C.M., F.R.C.P., of Rutland-street, Edinburgh, to Penelope Gordon, elder daughter of Patrick Heron Watson, LL.D., M.D., F.R.C.S.E. and I., Surgeon-in-Ordinary to the Queen in Scotland.

HART—RAWSTHORN.—On Sept. 25th, at Christ Church, Bolton, by the Rev. H. W. Reynolds, B.A., Vicar, George Hart., M.R.C.S. Eng., eldest son of Mr. James Hart, Pharmaceutical Chemist, to Mary (Polly), eldest surviving daughter of the late Mr. William Rawsthorn, of Bolton, Lancs.

LENDON—RYMILL.—On Aug. 26th, at St. Paul's Church, Adelaide, S.A., Alfred Austin Lendon, M.D. Lond., of North-terrace, fifth son of Edwin Lendon, formerly of Maidstone, to Lucy Isabel, younger daughter of Henry Rymill, J.P., of The Firs, East-terrace, Adelaide.

MARSHALL—DONALD.—On Sept. 25th, at St. Mary's, Bathwick, Bath, Arthur Lumsden Marshall, B.A., B.M. Cantab., fourth son of Major-General Marshall, late of the Royal Bengal Artillery, to Margaret Minnie Helen, youngest daughter of the late John Donald, Deputy Inspector-General of Military Hospitals, and granddaughter of the late Major H. B. Adams, Paymaster the Recruiting District, Dublin.

MILWARD—PLUMRIDGE.—On Sept. 26th, Surgeon Edwin Oswald Milward, Army Medical Staff, son of the late John Hartnell Milward, Esq., Ennis, Ireland, to Enid, youngest daughter of the late Admiral Sir James Hanway Plumridge, K.C.B.

STEPHENS—CRIPPS.—On Oct. 2nd, at St. Anne's, Eastbourne, Harold Frederick Dale Stephens, M.B., R.N., of H.M.S. Pembroke, eldest son of E. B. Stephens, Esq., The Lindens, Doddington, Cambridgeshire, to Agnes Grace, youngest daughter of Lieut.-General J. M. Cripps, B.S.C., of Elmcote, Eastbourne.

WATSON—HOLDEN.—On Oct. 8th, at St. Mary's Church, South Luffenham, Rutland, by the Rev. P. G. Dennis, B.D., Rector of North Luffenham, and the Rev. C. O. Watson, M.A., Rector of Morcott, brother of the bridegroom, Deputy Surgeon-General George Alder Watson, Bengal Army (retired), to Beatrice Blandina, daughter of the Rev. Henry Holden, D.D., Rector of South Luffenham, Hon. Canon, Durham Cathedral.

DEATHS.

DICKINSON.—On Oct. 2nd, at Pailton, near Rugby, George Murray Dickinson, Surgeon, aged 73.

FARIS.—On Oct. 1st, at the residence of his brother-in-law, North Great George's-street, Dublin, Surgeon-Major Thomas Faris, Army Medical Department, War Office, London, only son of the late Rev. Francis Faris, Vicar of Donard, County Wicklow, in his 44th year.

HEWLETT.—On Oct. 8th, suddenly, Thomas G. Hewlett, M.R.C.S., of Fairlawn House, Bedford, formerly Deputy Surgeon-General, Bombay Army, aged 57.

KYNOCH.—On Oct. 4th, at Invergordon, Ross-shire, N.B., Robert Keith Kynoch, M.R.C.S. Eng.

TIMES.—On Oct. 8th, at his residence, Manchester-street, Manchester-square, Henry Gorsuch Times, M.R.C.S. & L.M., in his 73rd year.

VOGAN.—On Oct. 5th, at his residence, Ipswich, James Norman Vogan, F.R.C.S. Eng., in his 37th year. Friends will please accept this the only intimation.

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editors."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed to the Sub-Editor.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "to the Publisher."*

We cannot undertake to return MSS. not used.

MALCOLM MORRIS INDEMNITY FUND.—FINAL LIST.

THE following additional subscriptions to the above fund have been received:—

Amount previously acknowledged	£466	8	0
Henry C. Burdett, Esq.	5	5	0
Dr. Brodie	3	3	0
Dr. Wharton Hood	3	3	0
Dr. Champneys	2	2	0
Dr. Robert Liveing	1	1	0
Dr. Goodhart	1	1	0
Dr. E. J. Nix	1	1	0
Colonel Stanley Bird	£1	1	0
Surgeon C. C. Manifold	1	1	0
Dr. Marcus Allen (Brighton)	1	1	0
F. O. Lovell, Esq.	1	1	0
D. B. Balding, Esq. (Royston)	0	10	6
Total	£487	18	6

Gentlemen who have promised subscriptions, but have not yet sent them, are requested to forward them to Mr. G. P. Field, 34, Wimpole-street, or to Dr. Sidney Phillips, 21, Upper Berkeley-street, W.

Mr. Thomas Tyler, M.A.—An organisation of the medical graduates into a separate Medical Council with any executive power would not meet the present difficulty.

Dr. Stanley Haynes.—Our correspondent's letter arrived too late for the correction to be made.

ALBUMINURIA.

To the Editors of THE LANCET.

SIRS,—I did not have an opportunity of perusing the discussion on albuminuria at the meeting of the British Medical Association at Leeds, as reported in THE LANCET of Aug. 24th, until a few days since. It appears to me the gist of it is to be found in Dr. Graves' remarks on Bright's disease in his Clinical Lectures, published more than forty years ago, and heard by me, then one of his pupils, as he delivered them several years previously. Dr. Pavy, at the above meeting, said that "albuminuria is now admitted to exist as a functional aberration, as well as associated with structural disease," apparently unmindful of the fact that Dr. Graves showed from various cases that an albuminous state of urine may depend on mere functional disease of the kidney, and that we may have Bright's kidney with albuminous urine, and *vice versâ* (Clinical Lectures, vol. ii., page 268). Dr. Pavy also observed that the above discussion was evidence of a "new departure." If that be so, Dr. Graves "departed" by the "new" road more than fifty years ago.

I am, Sirs, yours faithfully,

Oct. 8th, 1889. A PUPIL OF THE LATE DR. GRAVES.

MEDICAL PRACTICE IN SOUTH AFRICA.

To the Editors of THE LANCET.

SIRS,—My opponent is an unqualified practitioner who was formerly a sailor and deserted from his ship. Afterwards he became in turn a police constable and a butcher. He was attending a child who died yesterday. He is now making its coffin.—Yours truly,

Orange Free State, Sept. 13th, 1889. M.R.C.S., L.R.C.P.Lond.

RECRUITING DUTY IN RUSSIA.

DR. KILDINZHEVSKI, writing in a military medical journal of various local circumstances in connexion with recruiting commissions in Russia, complains that the official instructions for the accommodation of the examining medical officer are frequently not properly carried out. Instead of a light, warm, spacious compartment, the room, especially in villages, is small, low, damp, often extremely cold, and as often overheated, and, as the secretaries work in the same room quiet and silence are unattainable. Under such circumstances, and as the medical officer has to work from 8 A.M. until 4 P.M., a proper examination is hardly possible. The necessary instruments for such examination are wanting, too, such as an aural speculum and tables for the examination of sight, and even clean towels and water are often not to be obtained.

Mr. G. T. Sandiford.—British practitioners are generally excused attending the curriculum for the M.D. of Paris, and are usually excused some of the six somewhat severe examinations required of ordinary students. Special application must be made to the Minister of Public Instruction, who judges each application on its merits, and informs the applicant what examinations he will be required to pass. The fees amount to £50. The *Programme des Conditions d'Admission aux Écoles de Médecine* (Delalain Frères, 56, Rue des Écoles, Paris) can be obtained for a small sum. If the object be to obtain a licence to practise, there is a much simpler diploma—that of *officier de santé*—which will answer the purpose; but it must be obtained in the locality in which it is proposed to practise. Of course, the French language is essential for either diploma. The Brussels M.D. can be obtained without any knowledge of French. Further information can be obtained from the Students' Number of THE LANCET, 1889.

Dr. W. Henry Williams.—The qualification mentioned does not give the right to the title of Doctor.

An Invalid.—We think Florence is to be preferred to Rome.

BRITISH QUALIFICATIONS ABROAD.

To the Editors of THE LANCET.

SIRS,—Having read an article in THE LANCET of Sept. 7th, 1889, upon the effect of British registration in the colonies and abroad, as regards the privileges for medical practice afforded thereby, I wish to direct your attention to the misleading character of your assertions as regards Ontario. While it is true that the Medical Council of Ontario were compelled, previous to the passing of the Imperial Medical Act of 1886, to register legally qualified British practitioners, yet since the passing of that Act, and the insertion of the words "subject to any local law" in Section 6, relating to the privileges of registered persons, they have not been so compelled. Section 23 of the Ontario Medical Act declares that it shall be optional for the Council to admit to registration all such as are duly registered in the Medical Register of Great Britain and Ireland on such terms as the Council may deem expedient. As a result of this Act, the Ontario Medical Council will register only such as pass the Final Examination of the College of Physicians and Surgeons of Ontario, and pay all the fees, amounting to $100. I am myself a graduate in Medicine and Surgery of the University of Aberdeen, registered May 4th, 1888, and upon coming to Toronto to practise was, to my intense surprise and disgust, compelled to undergo the Ontario College of Physicians and Surgeons Examination before being allowed to register in this province. To prevent other unfortunates sharing the same fate unknowingly, I would ask you to give this publicity in an early issue of your journal.

I am, Sirs, yours truly,

Toronto, Ontario, Canada. AUSTIN D. ELLIS.

ANTIPYRIN IN PUERPERAL PYREXIA AND SUPPRESSION OF URINE.

To the Editors of THE LANCET.

SIRS,—The following notes of a case may be of interest to your readers.

Mrs. C——, aged nineteen, primipara, a well-developed and healthy young woman, was delivered of a fine child at 2 P.M., after three hours' labour from first stage to third. Whiffs of chloroform were given. Next morning she seemed very nicely, but had not passed urine. At 5 P.M. she looked flushed and restless. Temperature, 100°. No urine passed. I then administered twelve grains of antipyrin, and two hours later found that the patient had passed urine. She was quite comfortable; temperature normal. She made an uninterrupted and rapid recovery.

I am, Sirs, yours faithfully,

Hornby, Sept. 30th, 1889. IAN D. MACKAY, B.A., M.B., C.M.

CYCLING.

To the Editors of THE LANCET.

SIRS,—Would some of your readers kindly suggest the evils that may arise from steady pressure on the perineum as from a bicycle saddle? Cyclists all look on such pressure as an evil, but I am unable to hear of any case of injury arising therefrom.—Yours faithfully,

Taverham, Norwich, Oct. 6th, 1889. J. A. WARING, M.B. Oxon.

MEDICAL SERVICE AT THE LEEWARD ISLES.

To the Editors of THE LANCET.

SIRS,—There are two or three vacancies in the medical service of the Leeward Islands, and, as the Crown agents for the colony are probably endeavouring to obtain men to fill these appointments, I think the following facts should be made known to intending candidates.

The pay ranges from £200 to £250; the fees (vaccination, &c.) average £20. There is no pension, no "free quarters," no increase of pay with length of service; an officer on leave of absence goes on half-pay. House rent is high, living is expensive and unsatisfactory, the climate trying and uncomfortable for Europeans; and as for the work, it is simply heartbreaking—the lowest of low practice among the lowest of low Irish is nothing to it. Hitherto the medical officer has looked to his private practice for a means of living, and the very few leading practices in the colony are fairly respectable as to income. But all this is to be altered; the doctors appointed after this are to be transferred to any part of the colony as may seem fit and proper to the governor; the meaning of this is that His Excellency may, by a stroke of his pen, practically ruin a man who has a decent practice and has incurred his displeasure. These islands may be healthy, but they certainly are not so for doctors. The number of medical appointments in the colony is twenty-four, the average filled being twenty-two. Now during the last fifteen years at least sixteen medical officers have died, six have permanently left on account of ill-health, five or six have left for other colonies, and two have been dismissed the service after having been tried for manslaughter and acquitted. The bulk of the good practices are in the hands of colony-born men, and any young fellow coming out would be relegated to a country district, where the society and the chances of making a decent income are very small.

I am, Sirs, yours faithfully,

Sept. 16th, 1889. SENEX.

SULPHONAL.

To the Editors of THE LANCET.

SIRS,—Sulphonal has been lately extolled as a pure hypnotic causing a natural sleep, without any ill-effect or unpleasant sequela. I have now used it in about thirty cases, and find that it certainly has the power of causing sleep, but sleep of a character that can hardly be called natural, since the patients on awaking all more or less complain of a tired feeling, and so marked was this in two cases that the patients were scarcely able to lift their hands from the bed. Another effect I observed in three cases was a dilatation of the pupil and a marked sluggishness about its reaction to light and accommodation, and control doses proved that this was due to the drug. I have generally given it alone, and not in combination, in doses varying from ten to thirty grains, but prefer now to give eight grains twice in an interval of one hour. In combination with codeia, I find it extremely useful after labour, when there is sleeplessness and considerable after-pain.

I am, Sirs, yours faithfully,

Oct. 7th, 1889. C. W. HOGARTH, M.R.C.S., L.R.C.P.L.

THE HYPNOTIC SOCIETY.

To the Editors of THE LANCET.

SIRS,—I have recently received, in common probably with many other members of the profession, the prospectus of a newly formed Hypnotic Society, and as I take great interest in the scientific development of medical hypnotism, and am to a certain extent identified with its practice, perhaps you will allow me a few words.

The existing medical societies and journals afford full opportunities for its discussion, and experiments outside the profession with such a double-edged instrument as hypnotism are as useless as they are objectionable. I imagine few English medical men will be tempted to join such a society, and I believe that its foreign members are ignorant of the state of professional feeling in this country.

I am, Sirs, your obedient servant,

London, Oct. 8th, 1889. CHAS. LLOYD TUCKEY, M.D. Aberd.

RETIREMENT OF IRISH HOSPITAL PHYSICIANS AND SURGEONS.

To the Editors of THE LANCET.

SIRS,—Referring to your remarks last week on the rule in England of compulsory retirement of hospital physicians and surgeons, I may point out that no such rules exist in the Dublin hospitals; and, as a consequence, one finds old men in Dublin, many of them retired from active practice, still on the visiting staff of hospitals. As a result of this system, no young man in Dublin can hope to get on to the staff of a hospital unless a death vacancy occurs. I may instance the "Adelaide," "Steevens," and the "Meath" as at present the worst offenders in this respect. I am sure that most young Irish medical men will agree with me that it is time that some steps were taken to enforce compulsory retirement in Dublin hospitals.—Yours truly,

Oct. 8th, 1889. M.B.

COCAINE IN WHOOPING-COUGH.

To the Editors of THE LANCET.

SIRS,—I should like to take the liberty, through your columns, of asking if any of your numerous readers have tried the effects of cocaine in whooping-cough, and how administered—whether internally, or by inhalation. If the latter, in what form?

I am, Sirs, yours faithfully,

Church, Oct. 2nd, 1889. J. DEARDEN, M.D.

"WARNING TO HOSPITAL VISITORS."

To the Editors of THE LANCET.

SIRS,—The annotation in THE LANCET of the 21st ult., headed as above, recalls a similar case of fatal perforation that occurred here some years ago.

A young gentleman of great bodily strength and vigour was admitted on July 13th, 1881, suffering from *mania à potu*. The mental disease proved of short duration, and he became a voluntary patient on Dec. 17th. In July, 1882, he succumbed to a severe attack of typhoid, from which he was making a good recovery when his mother, who had come here to aid in nursing him, gave him a cupful of Irish moss jelly, which in a few hours was followed by great abdominal pain, collapse, and death. The patient had been most solicitous for food, and his mother was particularly cautioned not to depart from the diet prescribed. She, however, could not withstand his pleadings for solid food, and smuggled a cupful of jelly into the hospital. In the temporary absence of the attendant from his room, the patient eagerly swallowed the whole quantity, and with a fatal result.

In this case the most precise directions and cautions were deliberately and secretly disregarded by a lady of education and apparent sense. The sequel, however, was required to prove to her the danger of evading the regulations of the asylum and the rule of the physician.

The slip enclosed shows how we seek to enforce on the attention of visitors the usual caution as to gifts to patients.—Yours truly,

A. R. URQUHART, M.D.

James Murray's Royal Asylum, Perth, Oct. 3rd, 1889.

DENTITION IN UTERO.

To the Editors of THE LANCET.

SIRS,—It may interest the writers of letters in THE LANCET under the above heading to know that when I was a student at St. Thomas's Hospital I attended a woman in her confinement; the baby, to the surprise of all, had two incisor teeth well developed. I advised that the little one should be named "Richard," and I believe it was so called. The facts were noted at the time, and reported to the obstetric physicians, and are on record somewhere.

I am, Sirs, your obedient servant,

JAMES HENRY CLARK,

Sept. 9th, 1889. Government Medical Service, Jamaica.

Mr. L. H. Ruegg.—The only satisfactory claim to the title of "Doctor" on the part of a medical man is the possession of the degree of Doctor of Medicine from a university. The title can be given by anyone to a medical man with other qualifications as a matter of courtesy; but its proper use is that which we have indicated.

J. C.—Our Students' Number will give the information.

F.R.C.S. has not enclosed his card.

A. S. A.—We think a union would come within the meaning of the term "public body," whereas a mine or works of a similar kind would not.

Medical Diary for the ensuing Week.

Monday, October 14.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations, daily at 10 A.M.
ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1.30 P.M., and each day at the same hour.
CHELSEA HOSPITAL FOR WOMEN.—Operations, 2.30 P.M.; Thursday, 2.30.
ST. MARK'S HOSPITAL.—Operations, 2.30 P.M.; Tuesday, 2.30 P.M.
HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M., and on Thursday at the same hour.
METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.
ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.
CENTRAL LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M., and each day in the week at the same hour.
UNIVERSITY COLLEGE HOSPITAL.—Ear and Throat Department, 9 A.M.; Thursday, 9 A.M.

Tuesday, October 15.

GUY'S HOSPITAL.—Operations, 1.30 P.M., and on Friday at the same hour. Ophthalmic Operations on Monday at 1.30 and Thursday at 2 P.M.
ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 4 P.M.; Friday, 2 P.M.
CANCER HOSPITAL, BROMPTON.—Operations, 2 P.M.; Saturday, 2 P.M.
WESTMINSTER HOSPITAL.—Operations, 2 P.M.
WEST LONDON HOSPITAL.—Operations, 2.30 P.M.
ST. MARY'S HOSPITAL.—Operations, 1.30 P.M. Consultations, Monday, 2.30 P.M. Skin Department, Monday and Thursday, 9.30 A.M. Throat Department, Tuesdays and Fridays, 1.30 P.M. Electro-therapeutics, same days, 2 P.M.

Wednesday, October 16.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 10 A.M.
MIDDLESEX HOSPITAL.—Operations, 1 P.M.
ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour. Ophthalmic Operations, Tuesday and Thursday, 1.30 P.M. Surgical Consultations, Thursday, 1.30 P.M.
ST. THOMAS'S HOSPITAL.—Operations 1.30 P.M.; Saturday, same hour.
LONDON HOSPITAL.—Operations, 2 P.M. Thursday & Saturday, same hour.
SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN.—Operations, 2.30 P.M.
GREAT NORTHERN CENTRAL HOSPITAL.—Operations, 2 P.M.
UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.; Skin Department, 1.45 P.M.; Saturday, 9.15 A.M.
ROYAL FREE HOSPITAL.—Operations, 2 P.M., and on Saturday.
KING'S COLLEGE HOSPITAL.—Operations, 3 to 4 P.M.; Friday, 2 P.M.; Saturday, 1 P.M.
CHILDREN'S HOSPITAL, GREAT ORMOND-STREET.—Operations, 9.30 A.M.; Surgical Visits on Wednesday and Saturday at 9.15 A.M.

Thursday, October 17.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M. Surgical Consultations, Wednesday, 1.30 P.M. Ophthalmic Operations, Friday, 1.30 P.M.
CHARING-CROSS HOSPITAL.—Operations, 2 P.M.
UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.; Ear and Throat Department, 9 A.M.
HARVEIAN SOCIETY OF LONDON.—8.30 P.M. Dr. D. B. Lees: The Treatment of Pneumonia by the Ice Bag.
OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.—8.30 P.M. Address by the President (Dr. J. Hughlings Jackson, F.R.S.).—Mr. Robert W. Doyne: Case of Recovery from Hemianopsia, and subsequent Autopsy.—Mr. W. E. Cant: Case of Keratitis from Paralysis of Fifth Nerve after Injury. Dr. Reid: Trochoma, its Pathology and Relations. Living Specimens at 8 P.M.:—Mr. Lang: Two cases of Congenital Coloboma of the Iris.—Mr. Poulett Wells: Peculiar Retinal Detachment.—Mr. Quarry Silcock: (1) Exostosis of Frontal Sinus; (2) Double Proptosis, (?) Modified Graves's Disease.

Friday, October 18.

ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.
ROYAL COLLEGE OF PHYSICIANS.—4 P.M. Dr. James E. Pollock will deliver the Harveian Oration.

Saturday, October 19.

MIDDLESEX HOSPITAL.—Operations, 2 P.M.
UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.; and Skin Department, 9.15 A.M.

SUBSCRIPTION.

POST FREE TO ANY PART OF THE UNITED KINGDOM.

One Year ..... £1 12 6 | Six Months £0 16 8
TO CHINA AND INDIA ..... One Year 1 16 10
TO THE CONTINENT, COLONIES, AND UNITED STATES ..... Ditto 1 14 8

Post Office Orders and Cheques should be addressed to The Publisher, THE LANCET Office, 423, Strand, London, and crossed "London and Westminster Bank, St. James's-square."

ADVERTISING.

Books and Publications (seven lines and under) ..	£0 5 0

Lecture
ON THE
SO-CALLED PRESYSTOLIC MURMUR.

By W. HOWSHIP DICKINSON, M.D.,
HONORARY FELLOW OF CAIUS COLLEGE, CAMBRIDGE; SENIOR PHYSICIAN AND LECTURER ON MEDICINE, ST. GEORGE'S HOSPITAL; PRESIDENT OF THE PATHOLOGICAL SOCIETY.

GENTLEMEN,—You have probably noticed of late years occasional expressions of difference of opinion with regard to a cardiac murmur which some call presystolic, while others, who equally recognise it, hold that this term is erroneously applied to it. That the murmur is presystolic is for the present the view of the orthodox—a view which, while it is eminently respectable in its associations, is yet not antiquated, for it carries with it a reminiscence of recency as of something which was formerly new; and while it has the comfortable warrant of an accepted belief, is yet further pleasing as a discovery which belongs to the time of modern enlightenment. The murmur is one of the most characteristic which the diseased heart can produce. In common phrase, it "runs up to the first sound." I say it "runs up to the latter part of the first sound." It begins softly at the end of the silence which follows the second sound, increases in volume as it goes on, and terminates abruptly with a sharp short noise, like a knock or snap, which concludes the systole. The natural sounds of the heart may be, as you have often heard me say, represented by a trochee, with a short pause between each syllable, and a long pause between each foot. (Diagram 1.)

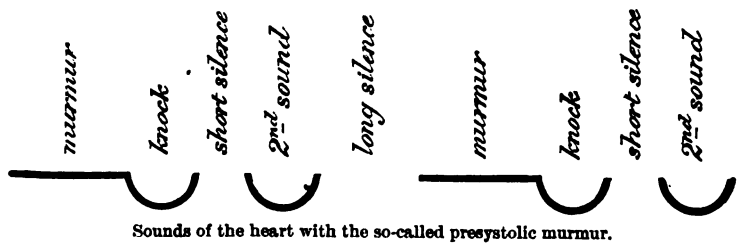

DIAGRAM 1.

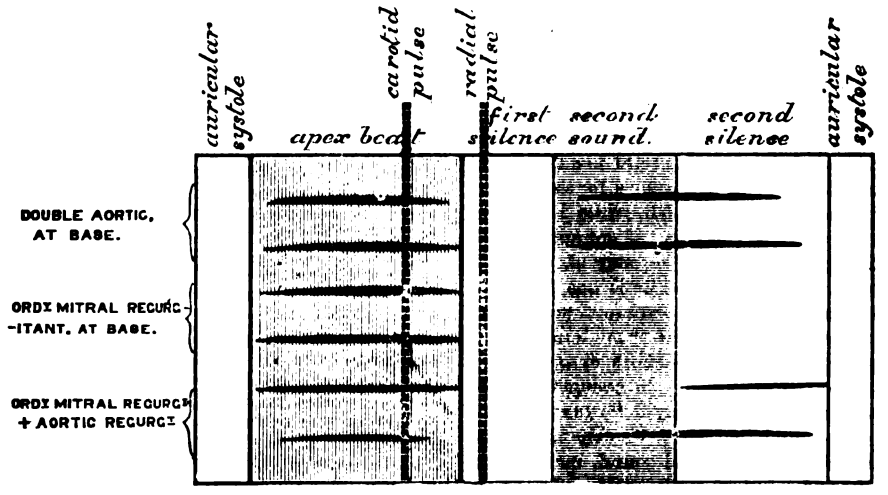
Sounds of the heart in health.

When the so-called presystolic murmur is present, the trochee becomes a dactyl, with the first short joined to the long, the second short following after a brief interval. The normal first sound is replaced by two sounds, which are distinct from each other, though separated by no interval: the first is a murmur, a noise of moving liquid; the second conveys the idea of arrest, and the use of such words as "knock," "slap," "snap." The combination of sounds and murmurs would now appear thus (as in Diagram 2).

DIAGRAM 2.

Sounds of the heart with the so-called presystolic murmur.

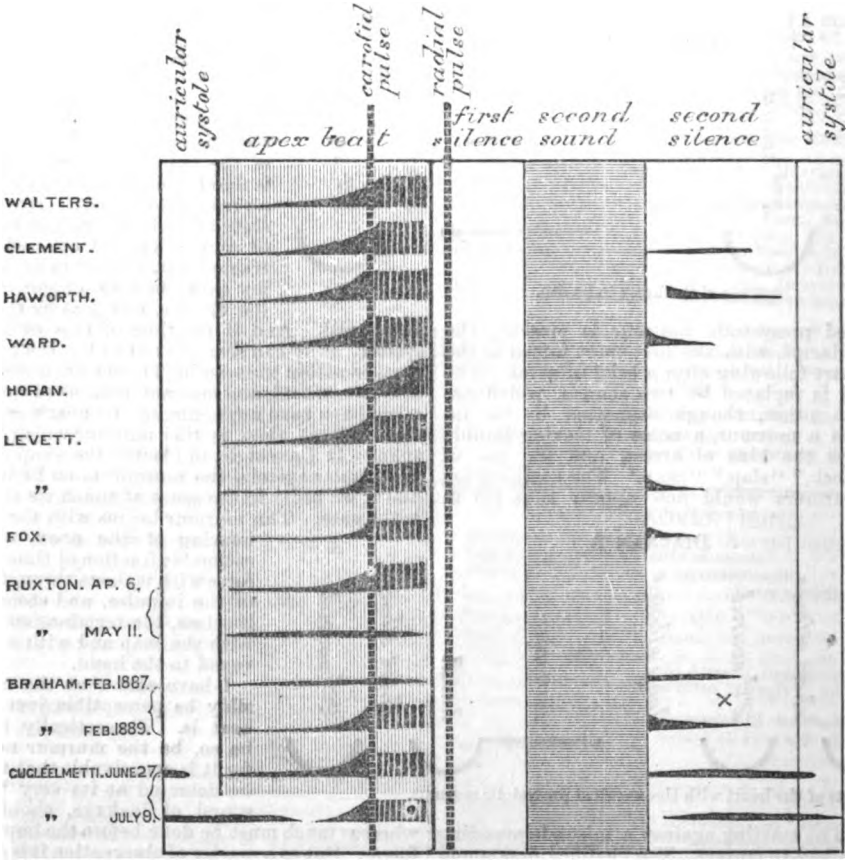
Let me warn you at starting against a misunderstanding which I have often had to correct. The modified first sound is so much like the second sound in character that I have many a time known the second to be described as a reduplication. Ordinarily there is no reduplication, but two independent sounds, one of which is mitral and systolic, the other aortic and diastolic. One has its maximum at the apex, the other at the base. Let us consider first what this knock or snap is, and what the heart is doing when it occurs. The snap ends the first sound; as to this there is no difference of opinion, though some would say it begins it too. After it comes the brief silence, which is succeeded by the second sound. The snap is generally synchronous with the carotid pulse, or, in other words, has the time of the latter part of the systole, to which the carotid pulse belongs. But more of this anon. Some would have it, indeed the presystolic theory implies, that the snap represents the whole systole; there is nothing before it but the murmur, and the murmur is presystolic. The murmur "runs up to it," as the phrase is. But not only is it beyond our comprehension that the whole of the expulsive action of the ventricle should be transacted within so short a space, but the relation to it of the carotid pulse shows that, when the noise in question is heard, the expulsive action is nearly over, is at least so far advanced that the blood has got into the neck. We cannot but infer that the ventricular contraction has been going on before the snap, which represents not the systole, but the end of the systole.



So much for the time of the sound in question. Now as to its origin. In quality it nearly resembles the normal second sound; but it is not this, for this comes after it and is separate from it. The character of the sound suggests that it is made, as is the aortic sound, by percussion. Its place associates it with the mitral valve, and its time at the end of the systole must be that of the closure of the mitral valve, if only that closure be a little delayed and be a little more abrupt than it should be. From clinical evidence, therefore, we should infer that mitral closure makes it, and this corresponds with what pathology shows. When this sound has been heard it is always found, as far as my observation has gone—I have carefully sought for exceptions without finding them—that the mitral flaps are thickened and the orifice contracted so that the valve is able to close, though from its stiffness it is to be presumed that the closure has been delayed, and to close in the manner of hard edges colliding rather than with the gradual yielding adaptation which belongs to the process in health. The mode of production of this sound is of obvious importance in relation to the nature of the murmur which precedes it. That it is due to mitral closure I think there can be no reasonable doubt. Dr. Kingston Fowler stated that he had recognised facets or marks of contact on the opposed sides of a contracted mitral valve in such a case. This to my mind is very important, for it proves the closure, and that by the evidence of an antagonist. And if the time of closure be the end of the systole, as it can scarcely fail to be, the precedent murmur must be within the systole. The closure is retarded by rigidity, as has been said, and may not occur until the sides of the ventricle have been approximated by nearly completed contraction. What, then, is this murmur which "runs up" to the snap? If I am right in placing the snap *at the end* of the ventricular systole, the murmur must be in its earlier part; and if we bring in the sense of touch we shall find that this is the case. The murmur begins with the first appreciable heaving of the apex, or an almost inestimable fraction of time before it, gathers force with it, lasts through the greater part of the impulse, and stops abruptly before its close, the termination being coincident with the snap and with a jar which is conveyed to the hand.

I have said that the murmur may possibly be perceptible just before the apex beat is. Theoretically this should often be so, be the murmur never so systolic; for it is conceivable that the systole should be detected at its very beginning by the sound of leakage, should a leak exist, whereas much must be done before the impulse can reach the finger. But as a matter of observation it is seldom possible to say that the murmur begins before the impulse or the impulse before the murmur; both seem to begin together, increase together, and stop together. Both begin softly and end suddenly in the slap or slam which ends the systole. The nature

Digitized by Google



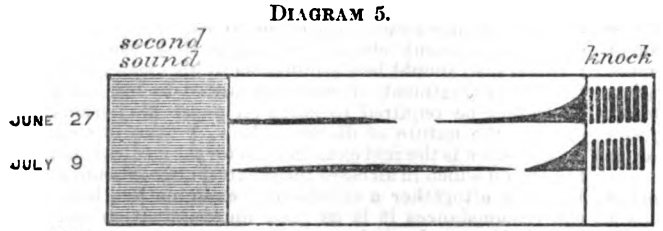
of the peculiar short sound which follows the murmur—the "knock," as I have called it—and its relation to the action of the heart are really at the bottom of the whole question. If the knock represents the systole, the murmur is presystolic. If the knock represents only the end of the systole, then the murmur is systolic. But the sound is one thing and the systole another. That the murmur "runs up to" the *systolic sound* none can question; but as to the *systolic act*, the murmur, I contend, does not run up to it, but arises in it, and runs almost through it. Let us consider what is the cause of the systolic sound. The muscular sound, the sound inherent to contracting muscle, has been

DIAGRAM 3.

Ordinary mitral and aortic murmurs, for comparison with next diagram. The ordinary mitral systolic are shown as going through the whole systole without abrupt stop. The aortic regurgitant begin sometimes within, sometimes immediately after, the second sound.

DIAGRAM 4.

"Presystolic" and diastolic mitral murmurs at apex in mitral stenosis. Murmurs are represented by a continuous horizontal mark, the knock by vertical lines. In many cases the so-called presystolic murmur is accompanied by a short diastolic or direct mitral, from which the presystolic is distinct. The two cases before the last show a not uncommon occurrence—a systolic murmur at one time, and a "presystolic" at another. In the latter phase of the last case the elongation of the diastolic murmur and the abbreviation of the "presystolic" prevented its fitting the table; it is therefore reproduced in the next diagram.



Digitized by Google

talked of; but no physician practised in heart disease can doubt that the sound is made within its cavity, or hesitate to accept as its chief factors the impact of blood and the sudden traction of cords, and striking together of valves. I need not seek to enforce what is self-evident. The thicker and more powerful the cardiac muscle the less audible is the sound, the thinner the louder. When the mitral valve fails to shut, not only is there no noise due to its closure, but by the consequent leakage the tension within the ventricle is lessened, and with it any sound which may be due to it. If any proper ventricular note survives in this portion of the systole, it is concealed by the regurgitant murmur which is developed. And so nothing is heard of the first sound until the valve flaps have got together, the regurgitation and the murmur been arrested, and the short sharp sound emitted which represents delayed closure and exaggerated percussion. This is the sound to which the murmur "runs up." Much of the systolic act is before it, together with the murmur which this act comprises.

The association of the murmur with the movement of the heart is best defined by the unassisted, or rather embarrassed, ear. Take a thin person in whom the impulse is well marked, and who has a double mitral murmur, diastolic and so-called presystolic. Familiarise yourself by touch with the heaving of the systole and the jar of the knock which ends it. Then place the ear upon the skin, or with only a thin cloth between, at the point of impulse, and let touch and hearing consent until your mind follows to your satisfaction the alternations of the ventricle. If your senses give like evidence with mine, the "presystolic" murmur will go with the impulse, the diastolic with the absence of it, the two being as distinct, as different, and as alternate as systole and diastole.

I have made a habit, with particular reference to this question, of marking the time of murmurs on physiological diagrams presenting the successive phases of cardiac action, and annex some woodcuts taken from them. Some of the divisions, that, for example, indicating the auricular systole, are matters of physiological rather than clinical observation. The positions of the apex beat, of the second sound, and of the carotid beat are of clinical ascertainment, under the guidance of which, as landmarks, the murmurs have been charted. The position assigned to the so-called presystolic murmur with regard to the apex beat involves the essence of the controversy, and of course is open to dispute. I have endeavoured to record the evidence of touch and hearing, unbiased by any inferences which might seem to be suggested, and have, wherever practicable, corrected or confirmed my own observation by that of others. I place first, for comparison, diagrams of the ordinary mitral regurgitant murmur—that is, of the mitral murmur with an uncontracted valve, and of the aortic regurgitant murmur. (*Vide* Diagrams 3, 4, and 5.)

DIAGRAM 5.

The last case represented in Diagram 4 is perhaps better shown in this, which is differently arranged, giving the second sound and the knock as the only indications of the place of the murmurs. The variable position of the break between the murmurs and the apparently variable length of the systole made it impossible to fit this case into the preceding scheme.

I next indicate in the same way the position of the so-called presystolic murmur, the murmur which is so often found with mitral contraction and never without it. The diagram needs no explanation. The murmur commonly runs through the systole, as I have satisfied myself, about as far as the carotid beat, and then is abruptly replaced by the terminal knock. I have represented the murmur by the uninterrupted black mark, the knock after it by separate vertical lines. But the diagram in many cases shows a second murmur; this is a very little one, and is more often absent than present, though present more often than generally recognised; it follows the second sound—that is, it takes place while the ventricle is expanding and the auricle contracting and the current setting towards the ventricle. What is this? By its time it might be aortic regurgitation; but not by its position, for it is heard only in the mitral area. It is best heard, often heard only, as the patient lies, being lost, or nearly so, in the erect posture. In this also the murmur is unlike aortic regurgitant murmurs; like those which belong to a contracted mitral valve. Neither is it accompanied by the pulse of aortic regurgitation. This little murmur, though of late years nearly lost sight of, will nevertheless reveal itself to the attentive ear in a considerable proportion of cases of mitral stenosis. I think there can be no doubt that it is truly auriculo-ventricular. I would say that it is the only murmur which can be correctly so termed. It is the old direct mitral murmur made from auricle to ventricle through a much-contracted mitral orifice. It is totally different in time and tone from the so-called presystolic which begins after it has ceased, but not immediately after, and rumbles up to near the end of the ventricular systole. If this be a direct mitral murmur, as it certainly is, are we to believe that the so-called presystolic is another? Is the heart to have two direct mitral murmurs with an interval between them? "Mon Dieu! v' la deux." Are both genuine, or is one a delusion? If both are auriculo-ventricular, it is remarkable that they should differ in so many respects—one soft short, and distinctly diastolic; the other intense, prolonged, and closely related to the systole, whether wholly within it, as is the present contention, or only in inseparable contact with it, according to the creed of the presystolic apostles. According to this creed we are to believe that two separate and distinct murmurs may be emitted by the blood as it passes from auricle to ventricle; the current is continuous, but the sound interrupted. It has been sought to explain this discontinuity by supposing that the first murmur, the mitral diastolic, is produced by the flow of the blood from auricle to ventricle, from causes antecedent to the muscular effort of the auricle; the second, the so-called presystolic, by the muscular effort which comes at the end of the flow. But at any rate the two modes of proceeding must be connected; we cannot assume a dead stop between the two, yet this we must do if we are to presume that the two murmurs are made in the same course of transmission.[1] We further find it necessary to accept in connexion with the same mysterious heart the dogma that the blood may change its direction at a valve, stop and go back, and the murmur not lose its continuity or change its tone. This is a hard saying, but not too hard for those who believe in the presystolic murmur. Let me make my meaning clear. It is a common experience for the so-called presystolic murmur to be so mixed with what all agree to call the systolic that it is impossible to say where one ends and the other begins, or to make any separation between the two; the "presystolic runs into the systolic," and with this phrase we are to be content without thinking what it involves. It involves the belief that the blood may flow from auricle to ventricle and murmur as it goes, and that the ventricle may then change from relaxation to contraction, the valve alter its pose, and the blood reverse its direction, and yet there be no jar, hesitation, or loss of continuity in that persistent tune.

Important evidence, or what seems so to me, is to be found in the relation of the carotid pulse to the heart's sounds. The carotid pulse in health comes, as is well known, within the systole, but near its end. I have satisfied myself, by careful and repeated observation, in these "presystolic" cases, with finger on carotid and stethoscope on heart, that the pulse in this artery is, as a rule, syn-

[1] The nearest approach to continuity between the mitral diastolic and the so-called presystolic murmurs was in the case of an Italian woman named Guglielmetti (Diagrams 4 and 5), who generally furnished a typical example of the two murmurs with their usual separation and distinctness; but on one or two occasions the first murmur was so prolonged that there was scarcely any interval between it and the second. The first murmur began immediately after the second sound, the second climbed up to the knock in the usual way; the only break which on one occasion I could detect was near the end of the combination, where shown in the diagram. It was here, I presume, that the direction of the blood was reversed. The shortness and lateness of the interval were exceptional even in this case, the usual condition of which is also shown diagrammatically. I may add that there was no doubt as to the existence of mitral stenosis, and to my mind none that the first as well as the second murmur was mitral.

Digitized by Google

chronous with the knock which concludes the murmur. Where the murmur has been unusually long I have sometimes thought the carotid beat to come just before the knock, so as to be within the murmur; but this is reckoning on small differences which may admit of doubt. Of this I am sure, there is no interval between the end of the murmur and the carotid pulse, this pulse becoming sensible to the finger usually at the same instant as the knock to the ear, the murmur equally "running up" to both. Now let us consider what this implies. The systole of the ventricle must go on nearly to its end before the thoracic vessels are filled and the blood lifted into the neck. Were the murmur presystolic—that is, did it depend on the passage of blood *into* the ventricle, not *out* of it—a considerable time must elapse between the murmur and the pulse for the transaction of the systole. But no such interval occurs; the murmur runs up without a halt to the carotid beat. Unless, therefore, the systole can be done up to the carotids in no time at all the murmur is systolic.

Two points in favour of the accepted presystolic theory are not to be ignored—the absence of the murmur from the scapular region and the thrill which accompanies it at the apex. A murmur in the stream from auricle to ventricle should not be heard in the back, away from which it goes; while any vibration the stream conveys should impinge with it at or near the apex. Both conditions hold with the so-called presystolic and not with ordinary systolic murmurs, and must have their due weight in the balance of evidence. But the absence of the murmur from the scapular region may be explained otherwise than as suggested, and attributed to the small amount of blood which regurgitates through the contracted opening which may not suffice to carry the sound as far and widely as does a larger gush. As to the thrill, the significance of this must depend on its time. If the thrill accords, as according to my observation it does, with the heaving of the apex it is systolic and not made as suggested. How it is made I have not to declare. The circumstances of blood thrills may be various.

To sum up the leading points against the presystolic theory they are these: As has been before urged, the loudness, intensity, and suggestion of force which often belong to the so-called presystolic murmur are incompatible with an origin in auricular contraction. Neither would the needful power seem to be provided by the suction action of the ventricle. This expansile action is a force which must be reckoned with; it has been too little regarded, but has importance in many pathological relations. At its utmost, however, it must be much less powerful than the contractile action, and, with mitral stenosis, must be feebler than it usually is owing to the smallness and weakness of the chamber. I assert that this murmur is heard at the same time that the heaving of the apex is felt. Whether the murmur begins a fraction of time before the impulse, as theoretically it should, or the impulse a fraction of time before the murmur, does not matter, so long as both go on together. That they invariably do this and also end together, my senses do not allow me to doubt. Further, the succession of the carotid pulse upon the murmur without an interval is an indication that this belongs to the contraction of the ventricle. In the next place there is a murmur which is made by the passage of the blood from auricle to ventricle, which is not that to which the term presystolic is applied. This is the genuine direct mitral, or mitral diastolic; it is different from the so-called presystolic in time and character, and when it accompanies it is disconnected from it. Finally, post-mortem observations are consistent with the view that the so-called presystolic murmur is regurgitant, and the knock, as it has been called, the sound of closure.

I would end with three questions, which, if they be answered in the affirmative, the rest will follow. Does the lifting of the chest wall as felt with the finger indicate the systole; does the murmur accompany the lifting; does the carotid beat follow the murmur without an interval? If these do so, the murmur is systolic. On these grounds I maintain that the so-called presystolic murmur is systolic, and is due to regurgitation before closure. I have but a limited expectation of converting those who have long held the presystolic theory. Old views, like old tissues, get indurated. My chief appeal is to the rising generation, and my personal belief, if I may be forgiven the expression of it, is that the time will come when the presystolic murmur will take its place among the errors of the past.

ABSTRACT OF

An Address

ON THE QUESTION

WHY SHOULD MEDICAL STUDENTS STUDY PHYSIOLOGY?

Delivered before the Medical Society of University College.

BY PROFESSOR MICHAEL FOSTER.

I WILL ask your permission to speak to you this evening for a short while in a familiar way, as an old medical student to a young medical student, concerning the question why medical students should study physiology. To this there is an answer which I am sure you will all be ready to give me—We study physiology because we are examined in it. I take it that the object of a medical examination—by which I mean, not the fancy examinations which are carried on by our Universities, but the examination which gives the diploma, or licence to practise—is simply to clear the way for the choice of the public. It would be possible for the public to have free choice in its selection of a doctor; it might be open to any patient to choose any man with a view to curing him, but in that case it might often happen that the patient did not live to see the result, and it has been approved by the world at large that a certain preliminary selection of men shall be made; and although it cannot be said that these are sure to cure or relieve, at all events, there is a fair presumption that they will be able to do so. Now, in the selection of these men, the most direct and experimental method that would naturally suggest itself—certainly the most direct means of ascertaining the ability of an aspirant to cure or relieve—would be to put into his charge a certain number of patients, sufficiently large to obviate any errors of chance, and to watch the result; but that, I think, would be a plan very costly and not unattended with danger. Hence society has come to require that a sort of sham tournament should be held, that the would-be medical man should be examined as to his ideas concerning the proper treatment of cases submitted to him, and that he should be required to state on paper his notions concerning the nature of disease. Now, I take it that this examination is the real examination for the medical man, and the one on which in all cases the greatest stress should be laid. It is not altogether a satisfactory examination, but under the circumstances it is as good an examination as can be held. Now, it is obvious that no one is fit to be let loose upon the public to cure their maladies who is ignorant of certain fundamental notions concerning the nature of disease. And these fundamental notions concerning the nature of disease cannot be taken in until certain notions concerning the structure and working of the human body in health have been acquired; hence it has come about that while the final examination is a preliminary selection of men who are probably fit to treat disease, there has been established another anterior preliminary examination in what we speak of as anatomy and physiology. Again, since an adequate knowledge of the structure and working of the animal body is impossible without some previous acquaintance with elementary physical laws, it has come about that there is another still anterior examination in certain elementary principles of chemistry and physics. Now I take it that that is all that ought to be included in a medical examination. A candidate is examined in physics and chemistry, not that he may be a physicist or a chemist, but that he may know enough of these things to enable him to understand the doctrines and teachings of physiology and anatomy, and he is examined in physiology and anatomy, not that he may become a physiologist or an anatomist, but that he may have that knowledge of the structure and working of the human frame which will prepare him for the due and rapid appreciation of the changes which take place in that frame in circumstances of disease, and he ought to know the nature of these changes if he is not to be a rule-of-thumb doctor, but a scientific physician.

Digitized by Google

I cannot conceive that the public has a right to demand anything more. There may be other things which are desirable in a doctor, but they are things which in my opinion are unnecessary for the protection of the public, and it is the protection of the public which is the basis of medical examinations. It may be very desirable indeed for the medical man to be a scholar, but the public has no right to demand that he should be one. It is far more needful that he should be a gentleman than a scholar, but you cannot put that into an examination.

The physiology the medical student requires is an acquaintance with its fundamental and elementary rules, but it must be a *real* acquaintance with them. He must know, for instance, thoroughly the laws which govern the movement of the blood, from the small arteries through the capillaries into the veins. And to know physiology really and truly he must be able to judge of the way in which its conclusions have been reached; he must understand its methods, and he must know the instruments, the results obtained by which are the foundation of a large number of the theoretical views. And although you do not want much physiology for an understanding of the principles of medicine and of the nature of disease, yet as wise men you would do well not to present yourselves at the examination loaded simply with just the necessary amount of physiology; you should always leave a margin for accident. I believe there are sometimes accidents in examinations. I know a friend of mine who was floored by the morning paper because he had eaten too hearty a breakfast, and I take it that in an evening examination a too hurried dinner will draw a veil between the examiner and the real ability of the candidate.

But there is another reason why you should go beyond that minimum. A medical examination, as I have said, is only a preliminary selection. It only says that this man is, on the whole, fit to take charge of the sick; your ultimate success in life will be the result of a struggle for existence, and your income will depend not merely upon your having satisfied the examiner, but upon the amount of skill which you will display in your life afterwards. Have you an amount of physiology beyond that minimum required by the examining boards to help you in this struggle? For if it will not help you, I, as a physiologist, have no right to ask you to take the trouble to learn it. But I am sure that it is in your interest to learn a fuller physiology, and though much of what you learn may be compared to scaffolding which must sooner or later come down and be displaced, yet at the same time there is a great deal of "real house," of firm basis, which will remain for all time. These real physiological truths require careful and prolonged attention in order that the student may lay hold of them, and he does this all the more readily if he carries on practical work in the laboratory. The latter work carries with it no special virtue of itself, for it is astonishing how much time the student may spend in the laboratory and yet remain quite free from any taint of physiology. The work to be done must be done not only with the hand, but with the mind, and he only will gain by it who, working in the laboratory at the things themselves, while looking at them reads in those things the lessons which they teach. The physiology which can be of use to medical men afterwards is the same physiology which is required of the candidate at examination—a real acquaintance with fundamental physiological notions; but the value of it will depend upon the way in which it is used. And let me here say how not to use it. You must not take the latest results of the laboratory and apply them direct at the bedside; for physiology is only as yet in its infancy; and in our notions of the nature of disease things are only at the same level. Nothing is to my mind more dangerous than the practice of taking, so to speak, "raw" physiology at once into clinical work; and if you look back on the history of the profession you will find that these attempts to take physiology straight off into practical use have proved delusive, and to my mind a great deal of discredit has been thrown upon physiology by these attempts. When I last addressed this Society eleven years since, I took as my subject the absolute identity between pathology and physiology, and I tried to lay before you the opinion that these two sciences were fundamentally the same; that they were only, so to speak, the two sides of one sheet. The great use of physiology to a medical man is to supply him with ideas which will help him in pathological and clinical investigation. Let him in practice use his physiology as a working hypothesis, and let him combine with this pathological and clinical observation, and out of it will come a true theory which will go far to cure the disease. Think for a moment of that great discovery of antiseptic surgery. Lister started as a physiologist, and the commencement of the antiseptic theory was a physiological idea worked out on pathological, clinical, and experimental lines. Take, again, the surgery of the brain; physiology has gone hand-in-hand with clinical surgery and post-mortem observation, and brilliant results have been attained. But though you may say you have neither time, opportunity, nor ability to make these medical inquiries, yet you can and must be critics and judges. I am astonished and gratified by the amount of physiology which I find has been introduced into practice, the amount of physiological knowledge now found common to the medical profession. But not all the physiology so found is good; much of it, indeed, is bad. Let the student, therefore, so train himself that he may be able to detect the bad—those physiological wolves in pathological sheepskins, which make their way into the medical fold and do so much damage. The greatest use of an adequate physiological training is to enable a man to detect in after-life with tolerable readiness those theories which are worthy, and to separate them from those which are worthless. To attain that faculty, and to let that physiological judgment get into your minds, you must give serious attention to its study. One great evil in life is that it is apt to be dull; the life of a doctor who takes no living interest in his profession is apt to be dull. Nothing will bring brightness to your life—not music, not even good dinners—if you do not find brightness in your daily task; but brightness may be got if you lay hold of your old physiological learning. Physiology has a mystery in her own right and a future of her own; physiology has not only to do with the mending, but with the making of men. If, in the intervals of leisure, you study it, you will find pleasure in it which will always prevent your life from being dull.

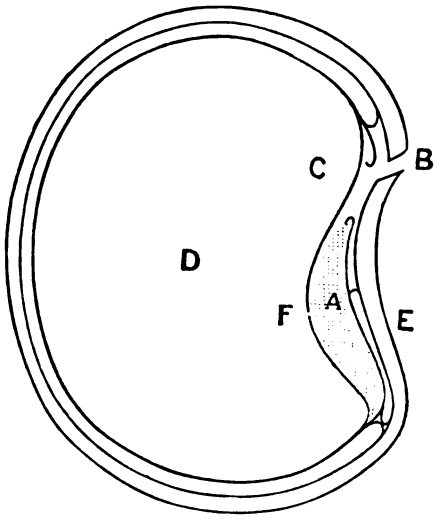
Clinical Lecture

ON

MASSAGE SCOOPS AND IRRIGATION IN THE EXTRACTION OF CATARACT.

Delivered at the Ulster Eye, Ear, and Throat Hospital.

BY DR. McKEOWN.



GENTLEMEN,—We shall consider to-day the most delicate and critical stage of the operation of extraction—viz., the removal of residual cortex. I may add also that it is the most uncertain, notwithstanding the accumulated experience of nearly two hundred years; for though a competent operator with a steady patient can make the section with absolute precision in every case, the most experienced cannot in many cases say whether he can or cannot remove the cortex by the ordinary methods of massage and scoop. It may surprise you when I say that these methods, which have been so long in use, are in a broad sense unsuited for the object in view, and therefore unscientific. You have had no opportunity of seeing in this hospital the use of the scoop at all, and massage has only been used in a very mild way, being only regarded and used by me occasionally as an auxiliary to irrigation. I shall try, however, to prove to you what massage is capable of doing and what it is not. To this end you must look at the physical character of the structures, and consider the conditions involved in the problem of extraction—a matter, I fear, which has not had sufficient attention.

You have now before you a rough drawing of the eye with pressure on the cornea exercised after expulsion of the nucleus. (Fig. 1.) This figure will explain to you better than I can do by words the inherent difficulty of removing cortex in any degree resistant. The soft, jelly-like vitreous (D) is the point, or rather cushion, of resistance; the force is applied at E, and causes a depression of the remains of the lens (A) and of the vitreous at F, with a corresponding bulging of

Digitized by Google

the vitreous at C, opposite the wound. It is obvious that, whether the remains of the lens (A) will be expelled or, on the contrary, the bulging vitreous at C, depends on the relative resistance of the remains of the lens (A) and the hyaloid membrane at C. If the cortex (A) be soft or, if not soft, be separated from the capsule, it may be rubbed and pressed out; but if neither of these conditions exist the

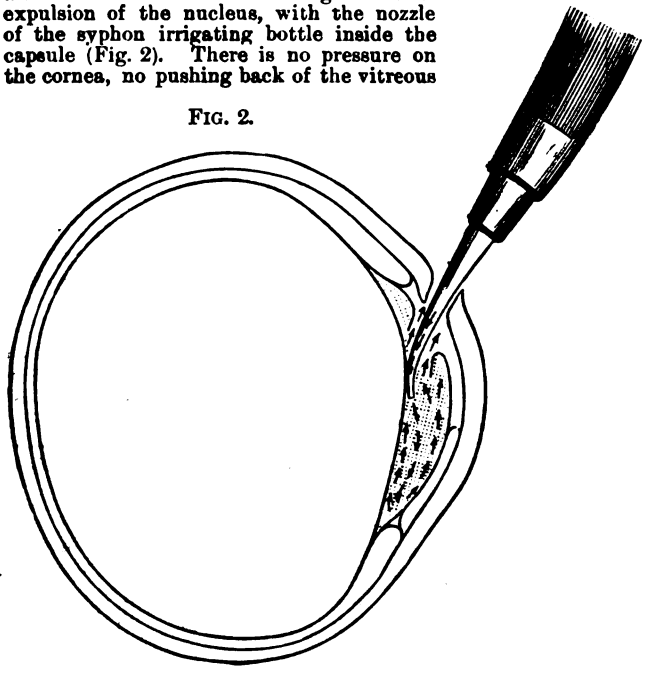


FIG. 1.

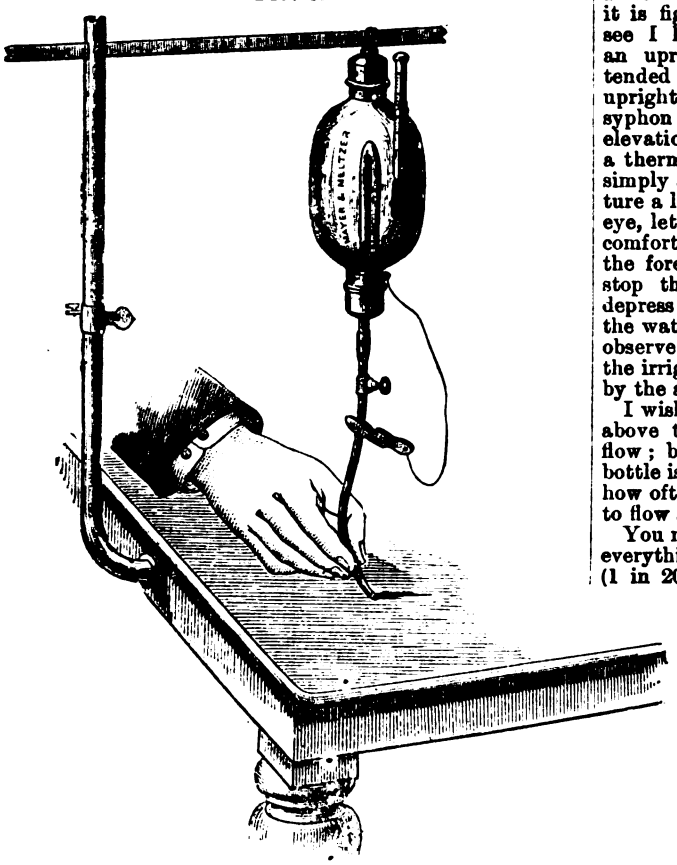
A represents cortex imprisoned in capsule after expulsion of the nucleus. B, Corneal section gaping on pressure exercised at E. C, Hyaloid membrane bulging towards wound. D, Vitreous. E, Cornea depressed by finger or scoop.

chances are that, notwithstanding all efforts, it will in great part remain in the eye a source of probable mischief. As you have never seen me perform an operation trusting to pressure and massage, you can have no adequate idea of the trouble and prolonged manœuvres often necessary and often fruitless. Whilst Fig. 1 is before you I show you now a sketch of the conditions in irrigation after expulsion of the nucleus, with the nozzle of the syphon irrigating bottle inside the capsule (Fig. 2). There is no pressure on the cornea, no pushing back of the vitreous

FIG. 2.

no squeezing of the hyaloid membrane towards the section. The current of water, under the control of the surgeon, flows inside the capsule to the periphery, and returns along the anterior and posterior capsule, searching every corner and bringing with it fragments of cortex from every part of the capsule. The force is equable and gentle, and acts not only on the parts we do see but on those concealed by the iris, and quite as well on the parts concealed as on the parts visible. In both cases an iridectomy is supposed to have been performed. With these two figures before you it must be clear that the complete extraction of cataract is simply a question of physics, of relative resistance and relative well-directed and suitable force; and, if I may prophesy, the method which will prevail is that which most accords with physical laws and conditions.



I now come, a little out of order, perhaps, to the use of scoops. The history of scoops is one of which the ophthalmic department of the profession has no reason to be proud. It illustrates very well indeed the tendency of the mind to get into a groove, to adopt views and practice without adequate inquiry and stick to them for generations, though warned of their general unsoundness by daily experience. St. Yves was the first to use a scoop. He removed by it a dislocated lens through a corneal section. For this sort of operation it was a proper instrument, and at this day for a like case it holds its ground. But when Daviel applied corneal section to remove cataracts, not dislocated but remaining *in situ*, he, probably following St. Yves in a way, used a scoop to remove, not the body of the lens, as St. Yves did, but fragments of the lens in the pupil after extraction of the nucleus. I cannot help thinking that, useful though the scoop of St. Yves was, and useful though the curette of Daviel may have been in isolated cases, this use of the scoop has dominated the surgery of cataract not to its advantage. Surgeons have not used enough the critical faculty, but have been too much led by a regard for names and authority. Indeed, from the time of St. Yves till quite recently ophthalmic surgeons have had fitful periods of a mania for scoop invention. They have followed St. Yves and Daviel, and, I think, without any satisfactory reason. I will now examine in a few words, as I did in the case of massage and friction, what the scoop can and cannot do as regards removal of cortex. I will begin with the old classical flap extraction, for a time recently under a cloud, but now happily revived. You know iridectomy was not performed, therefore, after expulsion of the nucleus, the only part of the lens area under view was that of the natural pupil—that is, about one-eighth or one-tenth of the anterior surface of the lens; and as the scoop could only be used to remove fragments seen by the surgeon, it could have any possible application on only the one-eighth or one-tenth of the field. I must speak quite plainly about this; and I say the use of the scoop was inapplicable for about nine-tenths of the field of operation, and even uncertain for the remaining tenth, and therefore was radically bad. But some may think that the combined operation of iridectomy with extraction remedied this to some extent. This is quite true, but, on the most favourable view, just about in proportion to the enlargement of the pupil. If iridectomy enlarged the pupil so as to expose one-fourth of the area of the lens, then the scoop might be used on one-fourth of the field, but on the other three-fourths it could not be used at all. All scoops, therefore, no matter by what distinguished names they may be called, must be condemned as inefficient on the ground I have stated. There are other objections to scoops, but it is a cardinal point in dealing with any question, that if you have an unanswerable objection you should not trouble to discuss minor points.

In view of what I have told you of the physical defects of the methods of pressure, massage, and scoops, you will not be surprised to learn that the bounds of legitimate operations for cataract have been comparatively limited. For the cataract should be of such a character that it could be removed by the methods of massage and scoop—that is, it should either be so firm from centre to capsule as to come out completely at once, or so soft all through, or on the surface, that all the lens could be removed. In fact, conditions were required which left little or nothing for massage or scoop to do. The surgeon judges by appearances, and if he determine that a cataract is ripe, he operates, and the accuracy of his diagnosis can be determined by the operation. So we have this important information, that operators of experience know that the diagnosis of ripe cataract is in a considerable percentage erroneous, and that the operation is attended with unforeseen difficulties. The consequences of such a mistake are very serious for the

Digitized by Google

patient, and the surgeon with only massage and scoop is simply powerless. On the other hand, when the surgeon diagnoses a cataract as unripe, he rarely operates, and in

FIG. 3.

Syphon irrigating bottle

cases of such a character there is therefore no means of knowing whether his diagnosis of unripeness is right or wrong. To sum up: when a diagnosis of ripe cataract is made, there is a varying percentage of error as regards the ease of perfect removal and a consequent risk to the patient; and when a diagnosis of unripeness is made, the patient is not subjected to the risks of an operation, but is put aside for months, and often for many years, with the prospect of a miserable life, and perhaps dependence on friends or on the doles of parochial charity.

I think you have seen so much here that you know these difficulties are all faced. With intraocular irrigation as practised here, I do not fear unexpected difficulties in the ordinary cases, and do not hesitate to operate on cases of transparent and sticky cortex—in other words, of unripe cataract. And why? Because I have a well-tried method, at least well tried in this hospital since 1884, and one which makes the surgeon, in a general sense, the master of circumstances. I cannot impress on you too strongly that for success in surgery the surgeon should be armed to meet all eventualities. I need not tell you, though I am sure it would be interesting, of the various stages of development of the method of irrigation and injection. I have devised and used various instruments of various degrees of efficiency and of varying defects, but this I have always had before me, that the force of pure water was the proper force to clear out the residue of the lens, and I have never seen any reason to change my opinion.

I show you now the instruments I have used since the spring of 1884, but I ask your special attention to the last one—the syphon irrigating bottle (Fig. 3). It is flat and holds about four ounces. In the inside of the bottle there is a bent tube, the bend reaching nearly to the top, whilst one end reaches to the bottom of the bottle, and the other end passes through the screwed-on cap at the lower end of the bottle. To the lower end of the tube is attached an indiarubber tube on which are a clamp to stop the flow of liquid and a ring with a screw to press the sides of the tube together and diminish the initial force of the flow. I do not know that the latter is of much use, but as it is figured in the diagram I allow it to remain. You see I have a horizontal bar moving up and down on an upright attached to the operating table, and I intended to have the syphon bottle suspended on the upright bar, but I have found it is better to have the syphon bottle held in the hand of an assistant at a suitable elevation. You see also a hole in the top of the bottle for a thermometer, but I have discarded the thermometer. I simply after charging the bottle with water of a temperature a little above blood heat, before I begin irrigating the eye, let the water flow on the back of my hand till it feels comfortably warm; then grasp the indiarubber tube between the forefinger and thumb just above the nozzle, and thus stop the flow, and introduce the nozzle into the eye or depress the lip of the wound and, relaxing my grasp, let the water flow, and stop the flow when I think it necessary, observe the effect, perhaps use slight massage, and renew the irrigation, being guided as to continuance and repetition by the appearance of the pupil.

I wish you to note specially that until the bottle is filled above the bend of the tube the water will not begin to flow; but once it has commenced it will go on until the bottle is emptied unless stopped by pressure, and no matter how often the clamp is applied the water will at once begin to flow again on its renewal.

You may have observed the care which is taken to have everything aseptic. A solution of perchloride of mercury (1 in 2000) is passed through the syphon bottle, then the bottle is rinsed with distilled water previously boiled, then the bottle is charged with distilled water likewise previously boiled and above blood heat, and the water allowed to flow through the tube before use. The tube in the bottle being of silver and the nozzle being likewise of silver, they are tarnished by the mercurial solution. I do not think that of importance in relation to the tube in the bottle; but I have the nozzle passed through the flame of a spirit lamp, rubbed, and washed by the flow of water before introducing it into the eye. The aseptic precautions described to you may seem unduly troublesome; but I cannot impress on you too much that cleanliness and attention to minute details are of the very essence of surgical success.

(To be continued.)

NOTES ON SOME CASES TREATED BY

SUSPENSION AT THE NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, QUEEN-SQUARE.

BY J. S. RISIEN RUSSELL, M.B.,
AND
JAMES TAYLOR, M.A., M.B.,
HOUSE PHYSICIANS TO THE HOSPITAL.

BY permission of the physicians, under whose care the various patients were, we are able to publish a list of some of the cases in which the suspension treatment as recommended by Charcot was tried at the National Hospital for the Paralysed and Epileptic, Queen-square. The cases here recorded are, it will be observed, all cases of tabes dorsali- with the exception of two—one of lateral sclerosis, appas rently primary, and the other of postero-lateral sclerosis, the "ataxic paraplegia" of Dr. Gowers. The apparatus used was the ordinary Sayre's apparatus, consisting of tripod with head and arm pieces suspended on a pulley. Suspension was done every other day, and in all the cases recorded here was the only treatment employed. Half a minute to a minute was the time allowed for the first suspension, and this was increased as rapidly as the patient could bear it, up to four minutes, which may be taken as the time of the last four-fifths of the suspensions in each case. In only one case (No. 10) were the suspensions done

Digitized by Google

daily; and whereas in the other cases four minutes was the longest time given to any one suspension, in this case three minutes was the limit. Both arm and head pieces were used, and as soon as the patient had acquired confidence he was directed to raise the arms slowly from the sides until the whole weight of the trunk depended from the neck. Patients, as a rule, were able to do this about every half-minute, but they varied greatly in the facility with which they could carry out the movement.

The inconveniences experienced by the patient were in most cases slight. During the first few suspensions some pain was usually complained of at the back of the neck, probably due to a stretching of the muscles in that locality. Occasionally, too, soreness of the jaws from the pressure of the chin-strap was experienced, and pain at the bottom of the back. One or two patients complained of faintness during some of the early suspensions. Two (Nos. 5 and 9) were subject to this even after they were well used to the treatment; one (No. 8) had so much discomfort at each suspension that he begged it might be discontinued, while two others (Nos. 14 and 16) had their symptoms so much aggravated that it was considered unjustifiable to persevere with suspension. There was a remission of the distressing symptoms as soon as the treatment was stopped. In all the cases where the ataxy was a symptom, if the patients were able to walk there was noticed to be some intensification of this symptom immediately after the suspension, and this continued sometimes even for an hour or two.

As to the results of the treatment, all that one is justified in saying is that three of the cases (Nos. 3, 5, and 11) improved while undergoing the treatment. One (No. 10) improved at first, but during the last three weeks he had a relapse, and when he left the hospital was certainly worse than he had been a month before. Another case (No. 4) had between April and June a course of twenty-five suspensions, but experienced no improvement. A month after this the ataxy became much more marked, and the suspensions were resumed. After ten suspensions he began to improve, and this improvement was maintained until he left the hospital. Considering the negative result of the first course of suspension in this case, the improvement during the second course can scarcely be regarded as anything more than a coincidence. Case 2 said that he thought he walked better and was more steady, but neither Dr. Ormerod nor the house-physicians observing independently could say that there was any improvement to be seen. Case 12 was one in which commencing optic atrophy was the prominent symptom, and although the patient himself said he thought his vision was better, careful testing could not confirm this.

In the cases in which improvement did occur, this consisted in a less ataxic gait and a greater steadiness in standing. In no case, however, was there ability to stand with the eyes closed, nor was there a return of the knee-jerk or of the pupil reaction to light. In one case the shooting pains were relieved somewhat, but in none of the cases had those been at once a recent and a prominent symptom.

In the greater number of the cases it will thus be seen that there was no improvement. Most of them remained practically in the same condition, but in more than one

SIXTEEN CASES TREATED BY SUSPENSION AT THE NATIONAL HOSPITAL, QUEEN-SQUARE, W.C.

No.	Name and age.	Physician's name.	Disease.	Prominent symptoms.	Duration of illness.	Number of suspensions	Results.
1	A. B., aged 44.	Dr. Ramskill.	Tabes dorsalis.	Total inability to walk; great incoördination in hands and loss of muscular sense; occasional retention; pupils reacted normally.	18 months.	30	No improvement; hands more useless than before.
2	C. D., aged 31.	Dr. Ormerod.	Ditto.	Marked ataxic gait; Argyll-Robertson pupils; no pains for several months.	2 years.	29	Said he walked more steadily; no objective change apparent to several observers.
3	E. F., aged 40.	Dr. Ferrier.	Ditto.	Marked ataxy; Argyll-Robertson pupils; no pains.	2 years.	30	Decided improvement in walking and greater steadiness in standing.
4	G. H., aged 49.	Dr. Bastian.	Ditto.	Great ataxy; occasional lightning pains; difficulty in micturition; Argyll-Robertson pupils.	7 years.	45	Between April and June had twenty-five suspensions; no improvement observed; in the end of June ataxy became much worse; suspension was resumed; improvement began after eight or ten suspensions, and was maintained.
5	J. K., aged 38.	Dr. Beevor.	Ditto.	Ataxy considerable; pains in loins; joint change in knee; Argyll-Robertson pupils.	3½ years.	33	No improvement until after twenty suspensions, then considerable improvement in walking; loin pain was still troublesome.
6	L. M., aged 49.	Dr. Ferrier.	Ditto.	Marked ataxy; pains in limbs, not severe; difficulty in micturition; Argyll-Robertson pupils.	3 years.	22	No change.
7	P. R., aged 38.	Dr. Ferrier.	Ditto.	Marked ataxy and occasional pains; Argyll-Robertson pupils.	7 years.	18	No change.
8	R. S., aged 41.	Dr. Beevor.	Ditto.	Ataxy; lightning pains and patchy anæsthesia; Argyll-Robertson pupils.	2 years.	18	Ataxy worse; more pain; patient begged to have treatment changed.
9	T. W., aged 34.	Dr. Beevor.	Ditto.	Optic atrophy; no ataxy; laryngeal crises; numbness.	5 years.	19	No change.
10	A. J., aged 41.	Dr. Ferrier.	Ditto.	Ataxy; numbness in limbs; no pains; Argyll-Robertson pupils.	3 months.	41	Improved at first in ability to walk and stand steadily; had a relapse in the last fortnight.
11	B. S., aged 35.	Dr. Jackson.	Ditto.	Marked ataxy; occasional lightning pains; Argyll Robertson pupils.	2 years.	30	Greater steadiness in standing, and gait is less ataxic; pains less severe.
12	C. R., aged 39.	Dr. Anderson.	Ditto.	No ataxy; pains six years ago; optic atrophy (primary); vision: right eye $\frac{1}{100}$, Jaeger 12; left $\frac{1}{18}$, Jaeger 1.	6 years.	30	No objective change while undergoing the treatment; he considers his sight better.
13	D. M., aged 44.	Dr. Ramskill.	Ditto.	Slight ataxy; extreme myosis and fixed pupils.	6 years.	15	No change.
14	E. L., aged 49.	Dr. Ferrier.	Ditto.	Ataxy (slight); Argyll-Robertson pupils; incontinence; diarrhœa; sickness occasionally.	4 years.	12	Had vomiting almost daily; diarrhœa continued; incontinence worse.
15	J. C., aged 25.	Dr. Ferrier.	Lateral sclerosis.	Rigidity of right leg, and consequent difficulty in walking; exaggerated knee-jerks and ankle clonus.	2 years.	30	Worse; rigidity greater; greater difficulty in walking.
16	G. J., aged 42.	Dr. Ferrier.	Postero-lateral sclerosis.	Ataxy; knee-jerks active; no pupil change.	7 years.	4	Always epigastric pain and nausea during suspension.

Digitized by Google

there was an evident retrograde tendency. As to the result of the treatment in the two cases at the end of the list—one of lateral sclerosis and one of postero-lateral sclerosis,—the former certainly became worse, as was evidenced by greater rigidity and greater difficulty in walking; the latter had epigastric pain and nausea during each suspension, so that it was considered advisable not to persist in the treatment, after he had had only four suspensions.

ON

TREPHINING THE SACRO-ILIAC JOINT IN SACRO-ILIAC DISEASE; WITH CASE.

BY MAYO COLLIER, M.S. LOND., F.R.C.S. ENG.,
SENIOR ASSISTANT SURGEON, NORTH-WEST LONDON HOSPITAL, ETC.

As the subject of sacro-iliac disease and its treatment is not generally so well understood as diseases of the other joints, I make no apology for placing the following case and the method of treatment I adopted for its relief before the profession. Before doing so, however, I propose to first give a brief sketch of the history, pathology, and treatment of the disease as propounded in this country and America. I am indebted to Dr. Weller van Hook of Chicago for most of the facts contained in this notice. It would appear from inquiry into the literature of the subject that opinions differ widely in this country and America as to the frequency, causation, and treatment of this affection. Professor Lewis Sayre says that in the United States sacro-iliac disease is quite common. Our best authorities here describe it as being a very rare affection. Professor Sayre again says it is always of traumatic origin. It is generally considered in this country as associated with struma or tubercular disease. Again, treatment differs widely. In America, fixation with extension and the application of the actual cautery appear, in the hands of Professor Sayre, to have been attended with very satisfactory results. In this country disease of the sacro-iliac joint is looked upon as a more or less fatal affection, and the treatment appears to be confined to rest in bed without fixation, and the opening or aspirating of abscesses as they present themselves. Mr. Arthur Barker, relating the experience of the surgeons at University College Hospital during a period of ten years in Holmes's System of Surgery, says the results of treatment in these cases have not been encouraging. Out of fifteen cases one is noted as cured, three as having died; five are stated as relieved, three unrelieved, one uncertain; two now in hospital are in a very critical state. With these facts before us we cannot but agree with Mr. Barker that the above results are not encouraging.

Turning to the history of this affection, one finds that the older authors make no mention of sacro-iliac disease. The first mention is by Boyer in 1821, who describes this disease as a chronic affection of the sacro-iliac joint due to a scrofulous taint, and similar to the affection causing spontaneous luxation of the hip-joint. Velpeau three years later describes having found pus in this joint during the puerperium, and looked upon this as an infecting centre of other suppurations found at autopsies. Larrey describes the disease under the term "sacro-coxalgie." He compares it to tumour albus of the other joints. In 1833 an article by Langier appeared in the "Dictionnaire Médicale" on the subject. About this time also Hahn published in German a more or less complete *résumé* on this affection. It would appear that between the years 1838 and 1847 no less than six theses were written on sacro-iliac disease for the Faculty of Paris. In 1853 Gurlt dealt with this disease in his treatise on the joints. In this country Mr. Erichsen was the first to give an intelligible account of this disease. In a lecture published in THE LANCET in 1859, he gave a clinical account of this affection, and clearly fixed many of the chief points in the differential diagnosis. After Mr. Erichsen had directed attention to sacro-iliac disease in this country, the subject was again taken up in France and America. Professor Sayre, from his great experience, was able in 1879 to refer in a clinical lecture to eighteen cases of sacro-iliac disease with one death. In his "Orthopædic Surgery" a short reference is all that is given of this disease, and an account of the operative interferences that he has resorted to in certain cases where abscesses had formed. By the industry of Dr. Van Hook, a summary of over fifty cases of sacro-iliac disease has been collected from the records of this country, America, and the Continent. For reasons which will be apparent, they are divided into two sets: 1. Those attended by suppuration. 2. Those not so attended. In number, 30 of the former and 21 of the latter.

Now, although it would be more satisfactory if the number of cases in these tables was 500 instead of 50, still some glaring facts are apparent. On looking at the table of cases where suppuration did not take place, out of 17 cases kept under observation till the termination 16 recovered, or 94 per cent. On the other hand, among 38 cases where suppuration did take place only 3 recovered without operation—that is, 7·9 per cent. The tendency of the disease is thus readily seen to be strongly unfavourable to life in the moist form; while in the form in which dry granulations persist throughout the disease the prognosis is favourable. Speaking of these figures Dr. van Hook says: "A natural division of therapeutic measures, as well as obvious classification for diagnostic and descriptive purposes, follows from these facts. For, if recoveries amount to 94 per cent. of all cases in which no abscesses form, we have certainly reason to be satisfied with whatever measures of treatment have contributed to that result. And since we know that cases in which the disease exhibited a dry form in the beginning may at a later period exhibit cold abscesses, we must adopt all possible means to prevent such a termination."

Now, it was with this most desirable object in view in the case detailed below, where from the great pain and constitutional disturbance suppuration was threatening, that I opened the sacro-iliac joint with a trephine. The desirability of this procedure to my mind was twofold. In the first place, to relieve tension and so prevent suppuration; and, secondly, if suppuration was present, to direct it to a less dangerous channel. When suppuration takes place in the sacro-iliac joint the pus pursues either an intra-pelvic or extra-pelvic course, rarely both. Of 55 abscesses collected, 21, or 38·2 per cent., were extra-pelvic—i.e., made their way directly posteriorly; while the remaining 38, or 61·8 per cent., entered the pelvic cavity. The fate of these cases was uniformly bad. Of the 21 extra-pelvic abscesses, 18 found their way immediately to the surface, 2 went up to the lumbar region to point there, whilst one only descended to the gluteal region. Turning to the cases of intra-pelvic abscesses, it will be readily understood that the situation of the ileo-psoas muscle immediately over the joint favours the passage of the products of suppuration along its sheath to a very important degree. Thus 4 abscesses dissected up to the lumbar region, while 18 followed this muscle down to lie embedded in the muscle sheath or to point near the insertion itself. The remaining 12 abscesses seemed to travel directly downwards, either, on the one hand, to pass through the sciatic notch, some to point over the gluteus which has been perforated, others to make their appearance on the posterior aspect of the thigh; or, on the other hand, to perforate the rectum, the perineum, or the anus. From this, we learn that an abscess pointing anywhere but directly over the joint is probably intra-pelvic, and the prognosis consequently grave. The following case is chiefly interesting from the fact that, although seen by several distinguished surgeons and physicians, the disease was not diagnosed till it fell into my hands.

C. W——, aged thirty-four, married; home South Africa. Has suffered for the last four years from pain in and about the right hip and lameness. No relief being obtained in South Africa, she came to this country in the early spring of last year for further advice. The case was sent to a well-known hospital physician of this city, who diagnosed the complaint as ovarian irritation, and treated it as such. Under this treatment the case not improving, a specialist on joint disease and surgeon to one of the metropolitan hospitals was consulted. He confirmed the diagnosis of the physician and recommended massage. Mrs. W—— still not improving, I was requested to see the case. At my visit I found her reclining in bed on the left side and supporting the body on the left elbow; she said she could not lie or sit upon the left buttock without pain. In answer to my questions, she said that her mother had died of consumption, her father was alive, but that her brother and sister both were weak in the lungs. She herself had had a severe attack of hæmoptysis two years ago, and was confined to

Digitized by Google

bed for eight months. The present trouble was attributed to lifting a heavy box. She was treated in Africa for hip-joint disease. On examination, the right hip-joint was normal, and the thigh was slightly flexed on the abdomen. There was nothing abnormal to be noticed front or back—no tumour or thickening in the pelvis to be made out. The patient complained of pain on walking or sitting on the right tuber ischii, pain on coughing, pain during micturition, radiating down to the pubes of the right side and down the right thigh; pain also on deep pressure in the right iliac fossa; pain on pressing the ilia together; pain also well marked on pressing immediately over the centre of the joint behind; occasional pain down the back of the right thigh and the right knee-joint. On walking, the patient stepped cautiously, inclining the body to the right side and advancing the right leg in front of the left. The toe was not everted. From these symptoms I had little doubt that disease existed in the sacro-iliac joint.

Sir James Paget kindly saw the case with me on the following Sunday and confirmed my diagnosis. A double Thomas' splint was ordered and tonics prescribed. The patient would not submit to counter-irritation in any form, having, as she said, been "nearly killed with blisters in South Africa." After the application of the splint matters did not mend. The patient suffered from almost constant pain, her nights were sleepless, and in fact she was running down very fast. Some local heat was apparent over the joint, but no general rise of temperature was at any time apparent, although the thermometer was used regularly throughout the treatment. With a view to surgical interference, I removed the patient from her apartments to St. Thomas's Home. Here the case was again seen by Sir James Paget, in conjunction with Dr. Edmunds. I proposed to trephine the joint from the outside, and my proposal was not dissented from, although not recommended by my colleagues. With the assistance of Dr. Edmunds and, in the presence of Mr. Makins and others, I proceeded to open the joint with a medium-sized trephine. When on the table a distinct swelling was noticeable over the joint about as large as the palm of one's hand. Examined per vaginam and rectum the pelvis was free from disease. A curved incision, eight inches in length, parallel with, and an inch below, the posterior third of the crest of the ilium, and descending vertically over the joint, exposed the bone sufficiently. The bone was next denuded with the elevator, and now was seen to be distinctly swollen and inflamed. A line being drawn from the anterior superior spinous process to the posterior superior, two inches were measured from this posteriorly. The pin of the trephine was placed on the line, so that the edge of the circle should be on the two-inch limb. The bone appeared softer than natural, the trephine rapidly penetrating to the joint. On removing the button of bone with the elevator a bed of soft fleshy granulation tissue was reached, fully one-third of an inch in thickness. The opposing surfaces of the joint were quite denuded of cartilage, and the bone on the sacral aspect was eroded, hard, and of a distinct yellow abnormal colour. The whole of the granulation tissue and dead bone, as far as could be reached, was removed with the gouge and mallet, the joint swabbed with chloride of zinc (forty grains to the ounce) and subsequently well dusted with iodoform. A large drainage-tube was inserted to the bottom of the opening, and the wound closed and dressed after the usual fashion. I need not weary my readers with the details of the case. Suffice it to say that all pain ceased immediately after the operation. The wound healed throughout by first intention, and at no time was a drop of pus ever present. The patient made an uninterrupted good recovery, and after a subsequent rest in the splint for six months left the home for the seaside, and has now returned to South Africa.

In conclusion, I would recommend that all cases of sacro-iliac disease where suppuration is threatening, or where pain is severe, be treated in a like manner.

New Cavendish-street, W.

ABERNETHIAN SOCIETY OF ST. BARTHOLOMEW'S HOSPITAL.—Mr. Oliver Pemberton, Professor of Surgery in Queen's College, Birmingham, on the 10th inst. delivered the introductory address on the occasion of the opening night of the session of this Society to an assembly of the staff, students, and nurses, the subject being on "The Progress of Surgery—a retrospect of forty years, and as to the measure of aid the School of St. Bartholomew afforded, both previously to and during that period."

THE

TREATMENT OF PURULENT OPHTHALMIA AND DACRYOCYSTITIS BY ANTISEPTIC IRRIGATION.

A NEW CANNULA FOR IRRIGATING THE LACRYMAL DUCT.

BY HUGH E. JONES,

ASSISTANT SURGEON, LIVERPOOL EYE AND EAR INFIRMARY.

THE object of this short paper is to show what success has in practice followed the treatment advocated by Mr. Edgar Browne for purulent ophthalmia and dacryocystitis. For the convenience of readers I have described the methods employed, and for those who may wish to try the treatment, the modifications which experience showed to be advisable. I am indebted to Mr. Richard Williams for permission to add two of his cases of gonorrhœal ophthalmia to those of Mr. Edgar Browne.

In his paper on "Some Points in the Treatment of Purulent Ophthalmia"[1] Mr. Edgar Browne said that the indications for the treatment of that disease were (1) to wash away the infective material as thoroughly and as early as possible; (2) to render the conjunctival epithelium and secretions as nearly as may be aseptic. He then described his own method of following out these indications by prolonged irrigation of the *whole* of the conjunctiva with a ½ per cent. solution of trichlor-phenolate of magnesium. The apparatus used consisted of an ordinary irrigating reservoir and tube and a lid retractor made of fine silver tubing perforated with six holes in the portion which entered the conjunctival sac. No cases of gonorrhœal ophthalmia in which this treatment had been employed were mentioned in that paper, though the results obtained in urethral gonorrhœa were given.

CASES OF PURULENT OPHTHALMIA.

CASE 1.—J. G——, a man aged forty-nine, was admitted to hospital on March 12th, 1886, suffering from gonorrhœa and gonorrhœal ophthalmia complicated by ulceration of the cornea. The lids were painted once with the nitrate of silver lotion (ten grains to the ounce). The conjunctiva was irrigated daily with trichlor-phenol solution. On March 17th the ulcer was healing. On the 22nd the discharge had quite stopped. The patient left well on the 30th.

CASE 2.—J. T——, a man aged thirty, was admitted to hospital on July 27th, 1886, suffering from gonorrhœal ophthalmia, complicated by a perforating ulcer of the cornea. The conjunctiva was irrigated three times a day with trichlor-phenol solution. By Aug. 4th the cornea was healing. There has been no extension of the ulcer since the patient's admission. On Aug. 13th the discharge had ceased. Cornea healed.

CASE 3.—M. P——, a woman aged thirty-eight, was admitted to hospital on Aug. 30th, 1887, suffering from gonorrhœal ophthalmia and deep marginal ulcer of the cornea. The lids were painted, on admission, with the nitrate of silver lotion (twenty grains). Afterwards the treatment consisted simply of irrigation with Panas' solution of biniodide of mercury, and the instillation of eserine. The ulcer began to heal on the day after admission. The patient was discharged on Oct. 18th. The ulcer had healed perfectly without perforation, and there was no permanent impairment of the vision. The long stay in hospital is accounted for by the patient's destitute condition and the depth of the corneal ulcer.

CASE 4.—M. C——, a woman aged twenty-three, was admitted to hospital on Dec. 3rd, 1887, suffering from gonorrhœal ophthalmia and deep marginal ulcer in the right eye, syphilitic iritis of the left, and well-marked syphilide on face and ulceration of tongue. The right eye was irrigated three times a day with Panas' solution, and the cornea dusted with powdered iodoform; the left eye was atropised. The ulcers of the tongue were touched with ac. hydrarg. nitratis and oleate of mercury ointment (10 per cent.) rubbed into the axillæ. The corneal ulcer began to heal the second day. On Jan. 20th the ulcer was quite healed. No discharge. Vision equals $\frac{20}{30}$; Jaeger 1, each eye.

Remarks.—With regard to the antiseptic solutions used,

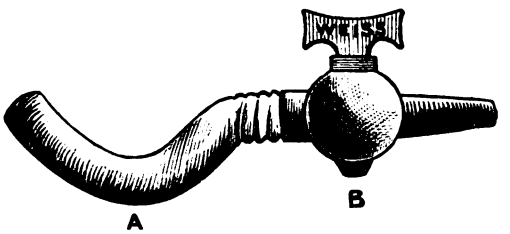
[1] Meeting of the British Medical Association, Belfast, 1884.

Digitized by Google

we found that Panas' solution of biniodide of mercury caused much less smarting than the trichlor-phenol (even when the latter was used as a ½ per cent. solution), and that though the treatment occupied a longer time, the final result was quite as good. In Case 1 Mr. Edgar Browne's irrigating lid retractor was used; in the other three I used an ordinary Eustachian catheter bent to a suitable angle, and found that, when passed well up into the conjunctival sac and moved slowly from one end to the other, it acted as well, or nearly as well, as the more elaborate special instrument.[2] In all the cases ulceration of the cornea had set in before admission to hospital, and in all healing began within a few hours of the first irrigation. The discharge was always much less on the second day, and ceased entirely within a fortnight, so that the patients could be transferred to the general wards. In all the cases I have seen treated by the older methods (nitrate of silver, iodoform, &c.) ulcers have gone on spreading until the discharge had nearly stopped, causing very severe permanent mischief to the cornea, and in some cases total loss. Irrigation was also found very useful in many cases of strumous and membranous ophthalmia, and in some of sloughing ulcer of the cornea with chronic conjunctivitis. In ophthalmia neonatorum, though shortening the duration of the disease very much, it was too troublesome and painful to be made the routine practice.

CASE 1.—A. B——'s (aged two years and a half) eyes became inflamed on June 30th after an attack of diarrhœa. No exanthem. The patient was admitted to hospital on July 5th, suffering from severe membranous conjunctivitis and keratitis. The treatment consisted of irrigation with Panas' solution, iodoform ointment, and gtt. atrop. (two grains to the ounce). On July 6th there was ulcer of the cornea. On the 8th the swelling of the lids had subsided, the membrane had disappeared from the conjunctiva, and the ulcer was healing. The patient was discharged well on July 13th.

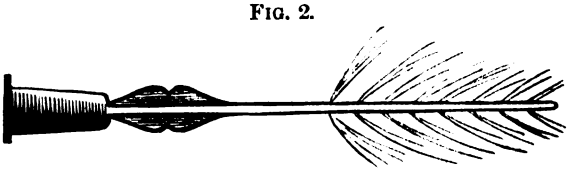
CASE 2.—K. G——, aged two weeks, suffering from ophthalmia neonatorum, was seen on June 25th as an out-patient. The conjunctivæ were irrigated with trichlor-phenol. The irrigation to be repeated daily. On June 29th the discharge had quite stopped. The patient was kept under observation until July 20th; but there was no recurrence of the discharge, though the treatment was limited to four irrigations.



DACRYOCYSTITIS.

In 1886 Mr. Edgar Browne,[3] recognising the important part played by pyogenic cocci—as shown by the researches of Sättler and Widmark—in diseases of the lacrymal sac and duct, applied the principle of irrigation to the treatment of lacrymal disease. As house surgeon it fell to my lot to carry out the details of the treatment. The object to be attained was practically the same as in gonorrhœal ophthalmia—viz., to wash away the discharge and to render the mucous membrane and its secretion aseptic without damaging the epithelium or aggravating the existing inflammation. In the first few cases an ordinary No. 1 gum-elastic catheter, to which the irrigator tube was attached, was passed down the lacrymal duct and trichlor-phenol solution (about ½ per cent.) used; but this was never a very satisfactory arrangement, as it was difficult to pass the catheter, and the solution caused very severe smarting. In all the cases recorded here the following was the method adopted. 1. The lower canaliculus was slit up sufficiently to admit a moderate-sized probe (except in some cases of lacrymal abscess, where the external opening rendered this unnecessary). 2. Weber's stilette and cannula (made by Matthieu, and figured in Juler's "Ophthalmic Science and Practice") were then introduced into the sac, the stilette withdrawn, the irrigator tube attached to the cannula, and about half a pint of Panas' solution run through. 3. Next day, supposing the sac not to be too acutely inflamed, a probe was passed, and afterwards the whole tract irrigated, the cannula being passed down the duct. In chronic cases, where the discharge was too thick and viscid to yield to ordinary means, about a pint of a ten-grain solution of bicarbonate of soda was used before the Panas' solution. 4. When a stricture existed a larger cannula was used every day until the stricture was sufficiently dilated. 5. During the process of irrigation it is necessary for the patient to hold his mouth wide open, for obvious reasons.

[2] A hollow irrigating speculum has been invented by Mr. Treacher Collins (vide THE LANCET, vol. i., 1885). [3] Practitioner, Jan. 1887.



The following objections to the instrument will probably occur to every ophthalmic surgeon: 1. If at all strongly curved, the withdrawal of a stiff, closely fitting stilette must be a difficult and jerky process. 2. If the cannula is introduced up to the hilt, the fluid irrigates not the lacrymal sac or duct, but the nasal mucous membrane. 3. If the cannula be withdrawn ever so slightly, it cannot, owing to its open end, be replaced without reintroducing the stilette. To avoid these difficulties, I got Messrs. Weiss and Son to make a cannula closed and rounded at

FIG. 1.

A, Rubber tubing from reservoir. B, Stopcock.

FIG. 2.

Cannula (small bore).

the distal end, and pierced along the sides by small holes for about one inch of its length. The proximal end was made to fit the tapering nozzle of a small stopcock. No stilette is required, for this cannula can be withdrawn and reintroduced to any extent with perfect ease and without detaching the stopcock; it, moreover, irrigates the whole of the sac, nasal duct, and part of the nasal fossæ at the same time. I used this cannula daily for four months. It serves its purpose admirably, and is kept clean quite easily.

CASE 1.—R. M——, aged thirty-seven. Seven months ago the patient had muco-purulent discharge from the lacrymal duct for three months, culminating in an abscess of the sac. This was followed by mucocele (four months), on account of which he came to the infirmary on Nov. 5th, 1886. The lower canaliculus was incised and a probe passed. On Nov. 6th, 7th, 8th, 12th, 14th, and 16th the duct was irrigated with Panas' solution. On the last-mentioned date the patient was quite well, there being no discharge or epiphora. In reply to questions, he wrote on Feb. 20th, 1889, saying that there was a slight watering of the eye six months after his last attendance, but that there had been no recurrence of the mucocele or abscess. The duration of treatment was eleven days; the number of irrigations six.

CASE 2.—E. A——, aged forty, was seen as an out-patient on July 2nd, 1886, with lacrymal obstruction and blennorrhœa. On July 2nd the lower canaliculus was slit. Probes were passed and boracic acid collyrium was used regularly until Oct. 25th, 1886—i.e., 114 days. From Oct. 25th and every day until Nov. 4th irrigation was practised. On Nov. 4th the mucous membrane was perfectly smooth and there was no discharge or epiphora. The patient remained under observation until Jan. 24th, 1888, without further treatment (except for mixed astigmatism and squint), during which time no recurrence of epiphora took place. Duration of treatment by irrigation eleven days.

CASE 3.—D. B——, aged twenty-six, was admitted to hospital on Jan. 25th, 1887, suffering from an old lacrymal abscess with recent recurrence. The abscess was incised. On Jan. 26th and 27th the abscess was irrigated, and the patient went home. On Feb. 1st fresh inflammation and discharge from the sac supervened. On the 4th the swelling subsided. As the patient lived at a distance, it was not possible to irrigate the duct oftener than once a week, and sometimes a fortnight elapsed without any treatment being applied. On March 4th rough bone was felt in the upper part of the duct. The patient ceased attending on April 19th. On this date he was quite well; no swelling or discharge, and duct smooth. During the whole of 1887

Digitized by Google

and 1888 the patient was seen at intervals of three or four months. Sometimes a probe was passed to test the patency of the duct, but no sign of stricture was ever discovered. Duration of treatment eleven weeks; number of irrigations about twelve.

CASE 4.—E. Q——, aged thirty-three. Lacrymal obstruction and blennorrhœa off and on for two years. Threatening abscess. On Aug. 5th, 1887, the canaliculus was slit and probes were passed. The blennorrhœa continued undiminished until Sept. 9th, when irrigation was begun and carried out daily until Sept. 20th, when the patient was quite well. In answer to questions, the patient wrote on Feb. 20th, 1889, that there had been no discharge from, or watering of, the eye since her last attendance in September, 1887. Duration of treatment by irrigation eleven days.

CASE 5.—W. S——, aged twenty-eight. Epiphora for three years, followed by mucocele. The canaliculus was slit and irrigation performed on Oct. 19th, 1886. The irrigation was repeated on Oct. 22nd, 24th, and 26th. On Nov. 19th the patient was quite well. Duct irrigated. Jan. 18th, 1887 (i.e., after two months), there was some thickening over the lacrymal sac, but no epiphora or discharge. On Feb. 20th, 1889 (i.e., two years and three months after cessation of treatment), the patient wrote to say that he was quite well. Duration of active treatment seven days; number of irrigations five.

CASE 6.—J. H——, aged sixty. Lacrymal abscess; ozæna. On May 20th the lower canaliculus was slit, and probes passed daily, without any improvement, until June 17th. The duct was then irrigated with bicarbonate of soda lotion, followed by Panas' solution. This was done once a week until July 22nd, when the discharge had entirely stopped. I was unable to trace this patient, so that I cannot say how long he remained well.

CASE 7.—A. M——, aged thirteen. Abscess of lacrymal sac. The abscess was incised, and irrigated daily for nine days. Two years later the patient was perfectly well. No recurrence of abscess or epiphora.

Remarks.—It may be asked whether this treatment has any lasting effect upon the stricture which, in many cases, has caused the mucocele or abscess. Cases 2 and 4 seem to me to show that it has, and the large number of cases treated during two years and a half have left a firm impression on my mind that the good effect is more permanent than in cases treated simply by the knife and probe, and that the formation of a stricture is more frequently prevented than by the ordinary methods of treatment, including the injection of astringents. Irrigation gains additional value from the fact that by it the nasal mucous membrane is treated simultaneously with that of the nasal duct and lacrymal sac, which must be of considerable importance in cases arising from or complicated by nasal catarrh or ozæna. I find that I have inadvertently included one or two cases which were mentioned by Mr. Edgar Browne in his paper in the *Practitioner*, but as they were then quite recent, and as I have since been able to trace them up to 1889, I have allowed them to remain. Many more cases might be given, but I think the above are sufficient to prove that the treatment advocated yields good results easily and rapidly.

P.S.—Since the above paper was written Mr. Treacher Collins has told me that during his house surgeoncy at Moorfields he used a cannula similar to the one described above, with a syringe. I am inclined to lay some stress upon the advantage of using an irrigating reservoir instead of a syringe.

Liverpool.

SALFORD ROYAL HOSPITAL.—The annual meeting of the subscribers to this institution was held on the 10th inst. in the board-room of the hospital, there being a good attendance. The report showed that during the past year 15,314 patients had been treated, against 14,152 in the previous year and 13,101 in 1887. The income had been £4826 and the expenditure £5955, leaving a deficit of £1129. The board had made an important modification in the way of admitting out and home patients in districts where there were few or no subscribers to the charity, and where there was consequently considerable difficulty in obtaining recommends. They had provided printed forms, which when signed by two householders certifying that the individual was a proper object of charity, entitled the applicant to medical assistance. The report was adopted.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

ON ANTIPYRIN.

BY ADOLPHUS J. RICHARDSON, M.A., M.D. CANTAB.,
ASSISTANT PHYSICIAN TO THE SUSSEX COUNTY HOSPITAL.

THE note on Antipyrin in THE LANCET of Aug. 17th, 1889, by Mr. Wingrave, induces me to give some details of its administration in a series of ninety-six cases, of which I have notes more or less complete. In only four of these has any bad effect been attributed to the drug. In a pregnant woman suffering from left-sided hemicrania, twenty minutes after she had taken ten grains an itching "white raised rash" appeared, diagnosed by a chemist as due to mussel poisoning. She had, however, taken nothing to which I could attribute it save the antipyrin. A patient with tabes dorsalis, after taking twenty grains fainted away, and is said to have lain insensible on the floor. One patient vomited after a dose of twenty grains, and one after a dose of ten grains; both, however, took it during a paroxysm of migraine, so it is very probable that the drug was not wholly to blame. In only the two above-mentioned cases was a larger initial dose than ten grains employed; I shall not repeat it. Thirty-eight of the cases were typical migraine; in nearly all I ordered ten-grain doses, to be repeated in an hour if the pain did not abate. In thirty-two cases the improvement was definite, in two doubtful, and four were unbenefited. In the successful cases, as a rule, not only were the paroxysms relieved, but their frequency was diminished. In three after a time the power of the drug seemed to fail, but an increase of the dose to fifteen grains produced the initial good result. In some cases, although the paroxysms were always relieved, their frequency was in no way affected. In none was the frequency increased. In two of the cases peptonuria was constant; both were relieved as to the migraine. The condition of the urine was observed in intervals as well as in paroxysms. Of the four cases in which the drug failed, one had, I believe, mitral obstruction, through which the migraine might have been aggravated; one vomited the antipyrin, probably before any therapeutic effects could have been obtained; the other two cases were both definitely hemicranias, and I have sometimes been tempted to think that the more definitely the migraine conformed to this type the less good was to be expected from antipyrin. In sixteen cases of head pain, some of which I could not explain at all, and none of which were markedly typical, the drug relieved in eight. A very different proportion to that on migraine, showing that the administration of the drug in a purely symptomatic manner meets with no undeserved success.

To detail the cases in which it failed:—1. Headache in anæmia, with possible gastric ulcer. 2. Violent vertical headache, possibly syphilitic. 3. Headache, associated with astigmatism (unrelieved by glasses) and gastralgia; improved under arsenic. 4. Vertical headache in a phthisical patient. 5. Rheumatism of scalp. 6. Continuous headache "all her life." 7. Temporal headache, possibly middle-ear disease. 8. Temporal headache.

In three cases of anæmic headache in chlorotic patients, contrary to my expectation, the drug relieved. These were not cases of migraine in chlorotic girls, but were headaches which were worse in the morning, unaccompanied by sickness or visual phenomena, and which got better as the day wore on, or on lying down. In four cases of tabes dorsalis, with lightning pains, my administration of the drug met with the most favourable results. All now invariably keep it ready for immediate use. One of the patients suffered from the most distressing nocturnal rectal tenesmus; on this the drug, although tried repeatedly, had no effect, but his lightning pains, of the most severe description, were at once relieved. Four times I have ordered ten grains to be taken at the onset of an attack of asthma nervosa, in all without any relief of the spasm. In three cases of facial neuralgia (in none of the patients was there any dental caries), one was much relieved and two but slightly; and it

Digitized by Google

is noteworthy that the most successful case had previously taken in vain croton-chloral hydrate and tinctura gelsemini, whereas one of the but partially successful cases was at once relieved by croton-chloral hydrate. Unfortunately, I know of no difference between the cases. In one case of brachialgia great relief was experienced after a vast variety of drugs had been futilely exhibited. One case of paroxysmal sneezing and two of severe pain in the feet with no apparent cause were relieved.

Hove.

SUICIDE APPARENTLY BY AN ATTEMPT TO CUT OFF THE HEAD FROM BEHIND.

By JAMES LITTLE, M.D.

I NOTICE in THE LANCET of June 22nd, the record of a case under the care of Mr. Hulke of suicide apparently begun by an attempt to cut off the head from behind. The forensic interest attached to this case induces me to publish the details of an even more determined case which occurred in my practice on July 2nd, 1879.

The case was that of a woman, aged thirty-six, who had been discharged apparently cured about a week before from Garlands Asylum, where she had been an inmate about three months, with the symptoms of puerperal insanity. About 8 A.M. on the above date the daughter of the patient came for me saying that her mother had attempted to commit suicide, and on arriving at the house I met a ghastly spectacle. She had a knife in her hand, and on the back of her neck was a huge wound, which had apparently taken half her head off. It had gone through skin, muscles, ligaments, the very bone itself, and had opened into the spinal canal, but had not touched the cord. The head itself, having lost all its connexions at the back, was bobbing about in a manner that would have been ludicrous had it not been so ghastly. The instrument was a blunt and rusty table knife, with which she had been peeling potatoes. On being questioned as to her object in committing suicide, her only reply was that she did not know. Such treatment as was possible was applied, but she died on the sixth day from septicæmia. No post-mortem was obtained.

The chief interest of the case lies in the fact of the wound having undoubtedly been committed by herself, and in the very determined manner in which she had set to work apparently to decapitate herself.

Maryport.

ACUTE PEMPHIGUS RESULTING FROM THE INHALATION OF SEWER AIR.

By MARK STYLE, L.R.C.P.L., M.R.C.S.

I HAVE lately had under my care two cases of what I have ventured to call acute pemphigus, which I attributed to poisoning from sewer gases. Both cases occurred in children, aged five and two years respectively. On being called to the elder child, my first patient, I was informed that he had been ailing for the past fortnight or so, losing colour and appetite. On the previous day two blebs appeared, one on the sole of the foot and another on the shin of the same leg. During my attendance others followed at irregular times during the following fortnight, chiefly on the thighs and legs, and two or three on the abdomen. There was some irritation from them, accompanied by febrile symptoms, anorexia, and constipation. The younger child's was a milder but similar attack, having only two or three bullæ, which did not recur after the first week.

The treatment I adopted was quinine internally, an occasional alterative powder, baths of warm oatmeal and water, and zinc ointment and calamine lotion locally. I find that Hebra and other authorities deny the existence of acute pemphigus, but class all acute bullæ as erythema bullosa, although since several cases have been reported. In my cases there was no erythema; each bulla was distinct, and until it attained some size had no inflammatory redness, even in the immediate vicinity; there were no smaller vesicles, as in herpes; nor was the skin of the part markedly red, as in erythema bullosa. I believe, too, that erythema bullosa occurs chiefly on the trunk and upper extremities; in both my cases the upper extremities were free. As both mother and nurse were particularly careful about the children's diet, which consisted mainly of milk and farinaceous food, I was rather at a loss to account for the presence of the eruption, until on making inquiries I found that a nasty smell had been noticed several times in the passage immediately outside the nursery. On inspecting the bath-room, situated just outside the nursery door, I found that the housemaid's sink was acting as a very efficient ventilator to the main sewer, the overflow pipe from the bath was joined to the down pipe from the sink, and although it had a U bend in it, which probably contained no water, as the bath was little used, there was a clean cut into the lumen of the pipe between the trap and the sink-pipe, so that we had a constant stream of sewer emanations entering the warm nursery by night and day. I concluded from my discoveries that this most insanitary condition of things was the cause of the illness; at any rate the evil was quickly remedied, and the children were soon well again. I may add this house was let with "all the latest sanitary improvements." If these cases were not cases of "acute pemphigus," may I call it pemphigus with acute symptoms?

Bromyard.

HIGH TEMPERATURE IN CHILDREN.

By W. J. TYSON, M.D.

IT is a well-known clinical fact how quickly the body temperature changes in children, and without this knowledge we should be constantly alarmed; yet I am afraid most of us do not really appreciate the above condition until we have been some years in practice. The cases that I am particularly referring to are those in which one is called to at night, with a temperature of 102° to 104°, pulse varying from 100 to 150, but the respiration, as a rule, not increased in the same ratio. On visiting the child the next morning the temperature is normal, or even subnormal, and the child apparently perfectly well. Some men will say that the medicine ordered, such as tincture of aconite, in drop doses frequently, a cooling saline, or a little grey powder, has been the means of lowering the heat. This may or may not be so, but my object in sending this note is rather to seek for a cause of the temperature than for the treatment of it. The most common cause is probably, I suppose, some form of error in diet, the offending food acting as an irritant upon the heat centre; another common cause is, I think, really a sunstroke; children in playing constantly throw off their caps and hats, and are exposed to the sun for many minutes. Doubtless there are other causes, but the above are the ones most commonly met with. The prevalent practice of people keeping their own clinical thermometers leads, in my experience, to the seeking of professional advice rather than the avoidance of it.

Folkestone.

A SIMPLE REMEDY FOR THRUSH AND SORDES.

By W. THEOPHILUS ORD, M.R.C.S., L.R.C.P.,
LATE RESIDENT SURGEON, BIRMINGHAM GENERAL DISPENSARY.

AMONGST the ill-fed children of the poorest residents of our large cities thrush is an extremely common and troublesome complaint. The following lotion, to be applied frequently with a feather or brush to the white patches, kills the oïdium albicans more quickly than any other I know, and removes the patches after a few applications, leaving healthy mucous membrane. It consists of equal parts of lotio nigra and glycerine mixed. I attribute its action to the germicidal power of the mercury. The quantity used is so small as to be quite harmless. Another condition in which I have found the same lotion invaluable is in that of the sordes which collect so abundantly on the teeth, lips, and tongue in many cases of enteric fever. It cleans these parts as if by magic, and renders that unpleasant process known as "scraping the tongue" quite unnecessary. It may also with advantage be painted over the fauces &c. in those unhealthy conditions of the throat which are so common in typhoid. I tried it in one case of catarrhal stomatitis, but it had no effect, whereas chlorate of potash effected an immediate cure. Also in the sordes of advanced phthisis it seems to be of no use. Not having seen this lotion mentioned in any book, and having found

Digitized by Google

it superior to any of the usual preparations in use for these affections, I venture to bring it to the notice of the profession, in the hope that it may prove as great a boon to other practitioners as it has been to myself.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Procemium.

PADDINGTON INFIRMARY.

TWO CASES OF HYSTERIA IN THE MALE; REMARKS.

(Under the care of Dr. SAVILL.)

WE give below two instances of the development of hysteria in the male subject, a condition which, as we have already said in the editorial notes of a previous case,[1] is not frequently met with in this country. Dr. Oliver[2] says that he has frequently witnessed its evolution as a traumatic sequel in the apparently robust and energetic labourer, and also adds that in both sexes it is a most intractable disorder, but is more amenable to treatment in the female than in the male. The ages at which this condition is most usually met with in males are about fifteen, or from thirty-five to fifty. We need not mention the special points of interest in these cases, as they are fully indicated by Dr. Savill in his remarks.

CASE 1.—James W——, aged thirty, a valet by occupation, was admitted into the infirmary on July 19th, 1889, complaining of general weakness, occasional sickness, giddiness, and obscure neuralgic pains in various parts of his body, which could not be associated with any objective signs. Indeed, he was a tall, well-built healthy-looking fellow, without any trace of effeminacy. His expression of face was rather suggestive of cunning. The thoracic and other viscera were normal and the testicles were normal in position and size, but on examining the abdomen there was marked hyperæsthesia all over. This hyperæsthesia extended a little way over the costal arches, and downwards over the front of the thighs. It was very accentuated over the inguinal region of both sides, and moderate pressure over this spot, which is known in the female as the ovarian region, gave rise to a choking sensation in his throat, sighing respiration, cries of "Oh, dear!" arching of the back into a condition of opisthotonos, and violent convulsive efforts to remove the pressure, followed by profuse perspiration and exhaustion. The tactile sensation in other parts of the body was normal, and there was no paralysis; but when Mr. Henrey tested the field of vision a few days later there was found to be a well-marked general retraction on both sides, and the field of vision for blue was smaller than the field for red—the order being from without inwards, yellow, red, green, blue; instead of blue, yellow, red, green, as in the normal eye. The fundi appeared healthy. Upon inquiry, he told us that he had been subject to nervous or "fainting" attacks all his life. These attacks occurred as often as every week or two, and would come on after "nervousness," or excitement from any cause. An attack commenced with profuse perspiration, then he would fall down, though without complete loss of consciousness, and after about ten minutes he came round, crying or laughing; an attack, he told us spontaneously, "brings on a bit of hysterics." On one or two occasions he had passed urine involuntarily, and often "ground his teeth," but never bitten his tongue. His mother, his aunt, and his only living brother had been subject to the same sort of nervous attacks. The patient himself had been a heavy drinker, and had indulged in sexual excesses from an early age, but otherwise there was nothing important in his previous history. No specific line of treatment was adopted, and he left the infirmary well on Aug. 14th.

Remarks.—The case presents a typical example of "ovarian phenomena," hysterical dyschromatopsia, and "faintings" in the male subject. In the case of this man, as in one previously narrated,[3] there was a previous history of venereal excess, and also a family history of the hysterical diathesis.

CASE 2.—Charles H——, aged fifty-five, a greengrocer, was admitted into the infirmary on June 7th, 1889. He appeared at first sight very ill, and wore a most distressed unhappy look, an aspect which he never lost and which was in keeping with the gloomy view he took of life. He told us in a whining tone of voice, and with much detail, that his illness dated from an injury he had received to his right ankle twenty-four years ago, that his right leg had been "paralysed" ever since, causing him to walk with a stick or crutch, although he managed to carry on his work; and that his left leg had gradually become paralysed without apparent cause eight months before, since which time he had taken to bed. There had been no incontinence. All his life he had suffered from headaches, had been very "nervous" and easily put out. He had lately been subject to attacks of "hot flushings," followed by "cold shivers" and trembling. In other respects his previous and family histories were negative. On examination, we found that he had a flaccid paresis of both lower extremities, more marked in the right; though it was by no means complete in either, for, or being held up on both sides and told to walk, his legs were thrown out and moved rapidly to and fro in the air like a paddle-wheel out of water. No paralysis elsewhere, but marked wasting of all muscles, especially of the right leg (the one injured), which measured one inch less in circumference than the left. Besides this atrophy no evidence could be discovered of the old injury. Upon striking any muscle or tendon of the body or limbs a very prompt and marked reflex could be obtained. A moderate tap on the patellar tendon of one side would produce a jerk not only in the leg, but also in both arms. Repeated blows of greater force were followed by a transient stiffness of the leg. Reflexes could be obtained also at the wrist, elbow, and lower jaw. Ankle and knee clonus were very marked on both sides, but clonus could not be obtained in the lower jaw. No inguinal tenderness or alteration of sensation. Field of vision not tested. He suffered very much during the first few weeks after his admission from severe frontal headache, but this subsided without treatment. He also had many pains in different parts of the body. We often had an opportunity of observing what the patient meant by "hot flushes and cold shivers." An attack would come on after some excitement, such as the doctor's visit, or perhaps without any cause. The face, and sometimes other parts of the body as well, became red and looked hot, though it did not feel so to the hand; next there would be profuse general perspiration. At this time the patient stated he felt cold, and there was occasionally some shivering. The whole lasted only a few minutes. Beyond the above symptoms no abnormality was discovered, the viscera were healthy, and the temperature was always normal.

The main treatment adopted was eminently psychical. In the infirmary he was of course removed from the conditions under which his disease had arisen, and a strict limit was placed on the visits of sympathetic friends. The patient was daily persuaded that if he only tried sufficiently he would be able to walk. At first this was only done by holding him up on both sides, then on one side; by-and-bye he succeeded with two sticks, then with one, and at the end of a month he was able slowly to walk the length of the ward alone. He was also placed on a liberal diet, given bark and acid internally, and had cold shower baths daily during the last month of his stay. He was discharged able to go to work on Aug. 9th, after two months' treatment, though he still limped slightly with the right leg, and there were still slightly increased tendon reflexes and occasional flushings.

Remarks.—The leading features in the case are: paresis of the lower extremities, irritability of all muscles and tendons, and attacks of flushing, followed by profuse perspiration. That the symptoms presented by this patient were not due to any gross lesion of the nervous system is sufficiently demonstrated by the absence of other symptoms usually associated therewith, and by the speedy cure (albeit after so long a duration) under psychical treatment, shower-baths, and tonics. Not the least interesting feature in the case is the occurrence of the flushings and sweats—

due obviously to some vaso-motor disturbance,—as showing the identity of the great neurosis (hysteria) in the two sexes. This symptom no doubt frequently escapes notice in the male, but is often very pronounced in the other sex, especially at the climacteric. I have described this case under the heading of hysteria, but there are two conditions—*species* of the neurosis—to which the case is undoubtedly allied, if not identical. (*a*) The *hypertonic* paresis described by Dr. Hughes Bennett.[4] In the cases to which this author refers the main features are paresis and exaggerated muscular irritability to percussion in varying degrees, and the one now under consideration differs from these in no important particular. (*b*) *Strychnism*, a term used by Professor Charcot[5] to denote the hyper-excitability of the grey matter of the spinal cord, which is presumed to be the anatomical condition attended by increased tendon or muscular irritability, and, if pronounced, by tonic and clonic muscular spasm. The precise anatomical nature of the change in these cases has not yet been demonstrated. It seems to me highly probable that Dr. Bennett's "hypertonic paralysis" and Professor Charcot's "strychnism" are very closely allied to each other, and that the muscular irritability in the case now under consideration belongs to the same category, and may be hypothetically explained by the same reasoning. But, whatever be the true pathological explanation of these cases, the highest importance attaches to their prompt clinical recognition; since with very few exceptions they are readily curable under appropriate means. The second of the two cases above described had been under treatment by several doctors. From what the patient told us, it is very probable that they had recognised the nature of the case, but they were unable, owing to circumstances, to carry into effect the cardinal principle in the treatment of such cases—namely, removal from the surroundings under which the disease had arisen. The patient expressed much gratitude at his cure; but it is doubtful if it will be a permanent one, for relapses are not uncommon in such cases.

HANTS COUNTY ASYLUM.

ACUTE PERITONITIS DUE TO PERFORATION OF INTESTINE IN A CASE OF LATENT TYPHOID FEVER; NECROPSY.

THE physician to a large hospital has opportunities of seeing at intervals examples of latent, or as it has also been called ambulatory, typhoid—cases of typhoid in which the symptoms have not been sufficiently severe to make the patient consider himself ill or abandon his occupation, until the supervention of hæmorrhage from the bowels or the sudden onset of peritonitis. The patient in this case took her food as usual, and, although under daily observation, presented no signs indicative of ill health until the morning of the day preceding death; and yet the fever must have been in progress for some time. Fagge[1] says: "The date at which peritonitis sets in is usually in the third, fourth, or fifth week. Cases have been recorded in which it has been as early as the eighth, ninth, or twelfth day of the patient's illness, but in all probability the disease has then really been of longer duration"; and, in speaking of peritonitis, he points out its possible cause as perforation of a typhoid ulcer due to typhoid "entirely latent." This perforation of a typhoid ulcer and the consequent peritonitis are the most dangerous complications of the fever. Murchison gives it that in this country 1 in every 33 dies of perforation, and that it is found in a fifth of all the post-mortem examinations made on patients who have died from the effects of typhoid. The occasional occurrence of this fatal complication in cases where the fever is so mild as to avoid recognition affords the strongest additional reason for maintaining complete rest and careful dieting in all cases, and especially in those attended only by prostration and so-called low fever. For the following account we are indebted to Mr. Morgan Finucane, senior resident medical officer.

E. C——, a female aged forty-nine, was under treatment in the asylum for mania, with delusions and some dementia. She was a tall thin woman, who had never shown any symptoms of illness until two days before her death. She took her food ordinarily, suffered more or less from constipation (a complaint well known as common amongst the insane), never complaining in any manner to nurses or patients in the same ward.

July 17th.—She complained of pain in the stomach this morning, and for the first time refused her breakfast. Her removal to the infirmary was ordered. A quarter of a grain of morphia given by hypodermic injection. The temperature was 100°. Abdomen quite hard and resistant, legs drawn up, and considerable pain on the slightest movement; tongue clean and moist; no sickness or headache. Temperature, 5 P.M., 99·4°; pulse small and weak. Hot fomentations to be applied and brandy given frequently; in the evening, at 7 P.M., she showed more definite symptoms of peritonitis.

18th.—Temperature to-day 101·2°. Legs drawn up; abdomen swollen and tympanitic; great pain; face pinched and drawn; bathed in profuse perspiration; pulse small and thready; taking brandy very frequently, but is rapidly sinking; hot fomentations frequently applied; no vomiting. Died to-day at 12.15 P.M.

Necropsy (July 19th at 9.15 A.M.).—The intestines were glued together by recent lymph, the surface of them being very much injected. The abdomen was filled with recent exudation. The ileum and large intestine showed undoubted typhoid ulceration with perforation of one of the ulcers in the ileum. The spleen was enlarged, injected, and very soft. Mesenteric glands enlarged.

Remarks by Mr. FINUCANE.—This case illustrates one of the difficulties medical officers have to contend with in asylums whose sanitary condition allows of the prevalence of diseases such as typhoid. The difficulty in the recognition of the disease is doubled in the case of the insane, and it is only by the systematic taking of the temperature of every patient daily (a no mean task in an asylum containing 1000 patients) that the prevention of such an unfortunate occurrence can be secured.

ALICE MEMORIAL HOSPITAL, HONG-KONG.

ANEURYSM OF THE ANTERIOR TIBIAL ARTERY; CURE.

(Under the care of Mr. J. BELL.)

ANEURYSMS below the bend of the knee are very rare, and few having a spontaneous origin are recorded; nearly all were the result of injury, usually wounds of the calf of the leg, and arose from the posterior tibial artery. Mr. Savory and Mr. Adams[1] have each recorded a case of aneurysm of the dorsalis pedis, apparently arising independently of injury. Mr. Erichsen had met with but one case of aneurysm of the anterior tibial artery;[2] it occurred in a man the subject of cardiac and renal disease, and was situated at the lower part of the upper third of the leg. Compression was without avail, and he left the hospital uncured. The cases recorded by Mathelin,[3] Page,[4] and Jamison[5] were of traumatic origin, but are interesting from the method of treatment adopted; and of the cases of Arata and Willard given in the collection of aneurysms of the posterior tibial made by Kinloch[6] the posterior tibial was similarly diseased in both. Willard's patient suffered from renal disease, and died after compression of the femoral.

Fung A. Ki, aged thirty-eight, a Chinese coolie, was admitted on July 19th, from the out-patient department, complaining of pain about the right ankle-joint and swelling of the foot. In the line of the anterior tibial artery and an inch and a half above the joint was a globular, pulsating swelling, about the size of a small orange. The ordinary symptoms of an aneurysm were all well marked, and the artery above and below the tumour was considerably dilated. There was no history obtainable of injury or syphilis, and in all other respects the man seemed perfectly healthy. The tumour was of two months' duration. The following day a consultation of the staff was held, and it was decided to try pressure by Martin's rubber bandage, and this was done. The leg and thigh were tightly bandaged, the sac being of course left full of blood. The knee was forcibly flexed and tied in this position. With the help of hypodermic injections of morphia this was kept on for five hours, but without any effect. Next

Digitized by Google

day Mr. Bell applied the same treatment for three hours, but on removing the bandage the pulsation was as distinct as ever. On July 23rd Martin's bandage was again applied, and Esmarch's tourniquet over the femoral above the bandage, the whole limb being wrapped in cotton wool. The pain was very severe, notwithstanding hypodermic injections of morphia, and after about an hour Dr. Thomson very kindly kept the patient under chloroform for an hour and a half. The tourniquet and bandage were then removed, and the students in relays kept up compression of the femoral for seven hours. All pulsation ceased on the application of the tourniquet, and never recurred. The patient was kept in bed, and for a few days wore a McIntyre's splint, to prevent his walking about the ward. At the end of a week he was allowed out for an hour on business, but stopped out all day, and returned at night none the worse for the exercise. On Aug. 19th—twenty-six days after all pulsation had ceased—he was discharged cured. The tumour was quite firm, and had shrunk to less than one quarter its original size. The rarity of this form of aneurysm may be judged from the fact that none of the nine medical men who were present at the consultation had ever seen a case before.

Medical Societies.

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.

AT the first meeting of the session, Oct. 10th, the PRESIDENT (Dr. Gwynne) delivered the opening address, upon the subject of "The Children of the Poor and their Diseases." He pointed out that the diseases generally observed among hospital patients can be in the main referred to either the scrofulous, the tuberculous, or the rachitic diatheses, and maintained that these various types of disease had their origin in the unhealthy conditions under which children are reared. He sketched out in the case of these three main types the relationship that subsisted between the causes that produced them and the effects produced. He maintained that, as society did not discountenance, but rather encouraged, immature and reckless marriages, the children of such marriages had a substantial claim to look to society for their protection. He deprecated the illogical expenditure of money by charitable organisations in rescuing individual victims, and the utter neglect of the causes that produced such lamentable results. He showed how inadequate medical art was to deal with the enormous mortality among children, and the vast amount of disease that resulted from causes that were in the main preventable. He pointed out the want of systematic instruction in the diseases of children at the medical schools, and recommended that attendance on a course of lectures on this subject and bedside instruction in the children's wards should be made compulsory on all candidates for medical degrees. To check the reckless procreation of children among the pauper classes, he recommended the raising of the legal marriage age, and the imposing of other restraints that might be deemed advisable. To relieve the congestion of the population in towns, he recommended emigration and a systematic method of colonisation in such countries as Western Australia, and the establishment of industrial schools in connexion with such colonies, where children could be trained to trades and employments most suitable to the country. He predicted that the gradual massing of the population in large cities and the resulting moral and physical evils would in the future compel the consideration of such social questions.

A vote of thanks for the address was passed on the motion of Mr. Favell, seconded by Mr. Garrard.

PATHOLOGICAL SOCIETY OF MANCHESTER.

THE annual meeting of this Society took place on Wednesday, Oct. 9th, when the reports of the committee and hon. treasurer were received.

The following officers were elected for the ensuing year:—President: Dr. Dixon Mann. Vice-Presidents: Messrs. G. A. Wright and C. E. Richmond. Treasurer: Dr. H. R. Hutton. Secretary: Dr. Thomas Harris. Committee: Drs. J. Collier, A. Donald, E. S. Reynolds, A. Robinson, W. Thorburn, and R. B. Wild. Auditors: Drs. J. Hervey Jones and P. Yates.

Multiple Exostosis.—Mr. A. H. YOUNG showed preparations from a case of multiple exostosis, and Dr. THOMAS HARRIS showed a patient suffering from the same disease.

Calcified Enchondroma.—Dr. HUTTON showed a specimen of partially calcified enchondroma from the leg of a dog.

Sarcoma of Scapula.—Mr. SOUTHAM showed two specimens of periosteal (round-celled) sarcoma of the scapula. In one case, a male aged fourteen years, where the tumour was confined to the subspinous fossa, excision of the scapula was performed. The patient made a good recovery from the operation, but afterwards succumbed to a recurrence of the disease, secondary deposits occurring in the lungs, liver, and bodies of several of the dorsal vertebræ, death being due to compression of the spinal cord. In the other case, a female aged eleven years, the growth involved the whole of the scapula and encroached upon the axilla. The scapula, together with the arm and outer half of the clavicle, were successfully removed, and the patient was alive and well at the present time, which was two months subsequently to the operation.

Angina Pectoris.—Dr. OWEN showed sections from the left ventricle and aorta of a case of angina pectoris. The muscular fibres, especially those of the musculi papillares, were in a state of marked fatty degeneration. The aorta for an inch from the base and in its whole circumference was roughened internally by atheroma, which rendered the wall rather more than double its normal thickness at this part. The sinuses of Valsalva were similarly involved, and the orifices of the coronary arteries, especially that of the left, to some extent occluded. Isolated patches of atheroma occurred also on the ascending arch. The right posterior valve was roughened with deposit, but the free edge was intact. The patient, a woman aged twenty-nine, had presented distinctive symptoms of angina, and had died somewhat suddenly. There was no evidence of kidney disease or syphilis. The cause seemed due to severe strain, to which the patient had been subjected for some months previously to the onset of the symptoms.

NORTHUMBERLAND AND DURHAM MEDICAL SOCIETY.

AT the annual meeting, held on Oct. 4th, the President, Dr. Murphy, in the chair, the hon. secretary, Dr. Oliver, read the financial report for the year. There are now 175 members in the Society. The officers were re-elected for the year.

Professor LAWSON TAIT delivered the annual oration, the subject being "Ectopic Gestation." He dwelt at considerable length upon the pathology of this condition, and showed the relationship which existed between tubal pregnancy and desquamative salpingitis. The operative treatment of the accident was thereafter discussed.—On the motion of Dr. Arnison, seconded by Prof. Philipson, a hearty vote of thanks was awarded to Mr. Tait for his address.

A banquet was held at the Assembly-rooms, Newcastle-upon-Tyne, and 140 members sat down to dinner, presided over by Dr. Murphy.

The first monthly meeting was held on Oct. 10th, the President, Dr. Murphy, in the chair. Nine new members were elected. Professor Lawson Lait was elected an honorary member.

Dr. ROBERTSON exhibited a man suffering from Cancer of the Larynx, upon whom he had performed tracheotomy in February last. There were now several sinuses above the wound leading down to dead cartilage.

Dr. DRUMMOND exhibited a man suffering from Diabetes Insipidus. Six months ago the patient was throttled by a fellow-workman. After the injury he bled at the mouth and nose. Seventeen pints of urine were passed daily, sp. gr. 1003; pulse only 60–64.—Remarks were made by Drs. Gibson, Oliver, and Redmond.

Dr. LIMONT exhibited a man suffering from Abdominal Aneurysm. The symptoms at first were pain and vomiting; now there are pulsation and well-marked bruit. He also exhibited a case of Aneurysm of the Right Carotid Artery. The physical signs were well marked. In both cases there was a history of syphilis. Dr. Limont likewise exhibited a woman suffering from Cerebral Tumour who had been trephined, with the result that she had regained conscious-

Digitized by Google

ness, the use of her right arm, and had recovered her speech. The tumour at present was again growing very rapidly.—Mr. Black, Drs. Gowans, and Drummond joined in the discussion.

Dr. OLIVER exhibited a boy suffering from Cerebral Birth-palsy. He detailed the physical signs, and dwelt upon the pathology of the affection.—Messrs. Redmond and Galloway, and Drs. Gibson, Gowans, Drummond, Murphy, Mantle, and Morison made remarks.—Dr. Limont also exhibited, with microscopical specimens, the lungs of a patient who died from Coal-miner's Phthisis.

Dr. BENINGTON read a paper on Gynæcological Work, in which he emphasised the necessity of making a careful physical examination in all cases with pelvic symptoms.

IPSWICH CLINICAL SOCIETY.

THE first meeting of this Society for the winter session was held in the Board-room of the East Suffolk Hospital on Wednesday, Oct. 9th.

Dr. CASLEY showed (1) a case of Strumous Disease of the Knee, in which arthrectomy had been performed; and (2) a case of Hydro-pneumothorax, in which the patient's condition had been much benefited by aspiration performed twice.

Mr. MYDDELTON-GAVEY read notes on a case of Alcoholic Paralysis.

Mr. JULER, F.R.C.S., read a paper on the Value of Ophthalmoscopy in Medical and Surgical Diseases, and specially dwelt on the importance of headache as a symptom of ametropia. He also demonstrated the methods of correcting errors of refraction by retinoscopy.

Notices of Books.

Elements of Pharmacy, Materia Medica, and Therapeutics. By WILLIAM WHITLA, M.D. Fifth Edition. London: Henry Renshaw. 1889. — Although this work appears under a familiar title, and is issued as a fifth edition, it has very obviously received considerably more attention at its author's hands than might have been anticipated. A large portion of the book has been entirely rewritten and several new features have been introduced which will greatly enhance its value. In addition, the arrangement of the different sections is altered. An index to the B.P.C. formulæ has been appended in small type, and the section devoted to non-official remedies has undergone very careful revision. In a concise form this book presents much valuable information, and will probably continue to be of service to intelligent students and to busy practitioners; the former will find that the arrangement facilitates their studies, while the latter may use it to refresh their memories upon subjects acquired in their student days, or to keep abreast of recent combinations and innovations.

Chemistry: General, Medical, and Pharmaceutical; including the Chemistry of the British Pharmacopœia. By JOHN ATTFIELD, F.R.S., &c., Professor of Practical Chemistry to the Pharmaceutical Society of Great Britain, &c. Thirteenth Edition. London: Gurney and Jackson. 1889.—Thirteen editions, English and American, in twenty-two years would place any book in the front rank of contemporary literature. Dr. Attfield's book is so well known that it needs no praise of ours, but we must once more commend it as one of the clearest, fullest, most accurate, and most generally useful scientific handbooks that any country can boast of. In spite of its compactness and moderate price, it is within its limits an encyclopædia of practical and theoretical chemistry. In the new edition the fame of the book has been well maintained by the revision of old and the incorporation of new matter. Among the additions we notice particularly the interesting account of ptomaines (p. 593), and of the sulphonic compounds, which have recently become so interesting because so important. Saccharin is already well known to be the sulphonic imide of benzoyl, but the new hypnotic, sulphonal, is a comparative stranger. For a wonder, it is not a coal-tar derivative, but boasts for its parents mercaptan and acetone, and for its scientific name, diethylsulphon-dimethyl-methane, or in symbols, $C(SO_2C_2H_5)_2(CH_3)_2$. We have recently had experience of its value in a case of advanced phthisis in a child of thirteen, who for a considerable time obtained refreshing sleep from it without a sign of subsequent ill effect. Dr. Attfield has greatly increased the value of his admirable book by the enormous index, comprising nearly 9000 references, which he has appended to it.

Hints to Travellers, Scientific and General. Edited for the Council of the Royal Geographical Society, by DOUGLAS FRESHFIELD, Hon. Sec., and Captain W. I. L. WHARTON, R.N., F.R.S., Hydrographer to the Admiralty. Sixth Edition. Pp. 430. London: The Royal Geographical Society. 1889.—This is the sixth edition of an excellent work first published in 1854. The information on the various subjects treated has been brought up to date by men in every respect competent for the duty, and whose names are a sufficient guarantee for its accuracy and value. While originally intended for explorers of countries little and imperfectly known, there is much in it, in its present form, which will be found useful for travellers in more civilised regions who wish to make their travels pleasant and profitable in the way of increasing their knowledge. The advice given by Mr. Freshfield in the preliminary hints may be usefully studied by all who go abroad, whether on duty, for amusement, or in search of health, as it may enable them to avoid much annoyance and thus enhance the pleasures of foreign travel. The medical hints by Surgeon-Major Dobson, late of the Army Medical Staff, deserve the careful consideration especially of those who are about to visit countries where medical aid is not easily to be obtained. We miss, however, in his remarks upon the general feeling of lassitude often experienced after prolonged physical exertion a reference to the value of small doses of opium, at least in cases where the strain is likely to be only temporary; nor does he notice the beneficial results obtained from the hypodermic administration of quinine in the graver forms of sunstroke. We recommend the "Hints" strongly to the notice of all vacation travellers and tourists who desire to increase their knowledge and add to the enjoyment of their leisure.

Father Damien, a Journey from Cashmere to his Home in Hawaii. By EDWARD CLIFFORD. London: Macmillan and Co.—It does not fall to the lot of everyone to visit a leper settlement, and to be the means of conferring pleasure on the inhabitants, but this Mr. Clifford, the well-known artist, has been able to do, and to make use of his advantages by writing an interesting little book on Father Damien and his work among the lepers. The substance had already appeared in three articles in the *Nineteenth Century* minus the introduction. Mr. Clifford went out to Molokai with gifts from various people for the afflicted population. He says there is no doubt leprosy has assumed a milder character of late years in the Sandwich Islands, and that as a rule lepers do not suffer severe pain. The length of life usually is four years from the commencement of the disease, after which time it generally attacks a vital part. Mr. Clifford induced Father Damien to try gurjun oil, with marked beneficial results; his appearance was much improved, and after a short time he slept better, and was able to sing, but the disease was too far advanced to be cured. It is well known how beneficial gurjun oil has been amongst lepers in the Andaman islands. Mr. Clifford draws attention to the terrible dangers of leprosy incurred by the natives of India. He quotes Mr. Kirkman, who denounces the defective regulations on leprosy in India.

Digitized by Google

Lepers sit about rubbing their sores on the railings of the Elphinstone High School, and school being over, scores of boys sit and lean on these very railings. Lepers also perform their ablutions in the same tank as healthy people. Surely the self-devotion of Father Damien and others who devote their lives to these miserably afflicted people ought to stir up the British Government to make strenuous efforts to prevent the spread of leprosy in India. Mr. Clifford's book contains touching pictures of Father Damien's holy life and death.

Dictionary of National Biography. Vol. XX. (Forrest—Garner). Edited by LESLIE STEPHEN. London: Smith, Elder, and Co.—Volume XX. of this comprehensive work contains over 500 biographies, between twenty and thirty of which have reference to members of the medical profession. Amongst these may be mentioned John Fothergill (1712–1780), who, after graduating at the University of Edinburgh and coming to London to practise in 1740, was admitted a Licentiate of the College of Physicians on Oct. 1st, 1744, being the first graduate of Edinburgh thus admitted; John Milner Fothergill, M.D. (1841–1888), the writer of several well-known medical works; Simeon Foxe, M.D. (1568–1642), President of the College of Physicians from 1634 to 1640, and to which College he bequeathed a sum of £40. Dr. Foxe was buried in St. Paul's Cathedral, and he bequeathed a sum of £20 "towards ye repayring of ye same Cathedrall." The name of Fryer occurs six times, five of the Fryers being medical men. Dr. John Fryer, who was President of the College of Physicians in 1549 to 1550, seems to have possessed some sense of humour. He had attended the Bishop of Rochester in his last illness. On the Bishop's death his goods were seized "to the King's use," so that for twelve days' labour and four nights' watching Fryer received nothing. Thereupon he besought Cromwell's mediation on his behalf, observing: "Except your lordshype be good to me, I shal bothe lose my labour, my frende, and also my physycke; and truely if physycyens shuld take no monye for them that they kyll, as well as for them that they save, theyr lyvyngs shuld be very thynne and bare." As regards the amount of his recompense and reward for his pains, he remarks: "I beseche your lordshyppe it may be so motche the mor lyberall, becawse it shalbe the last payment; for of them that scape, we may take the lesse, becawse we hope they shale ons cum agayne in to our handys." The type and general get-up of the volume are all that can be desired.

Manual of Musical Drill and System of Physical Training, for the use of Schools. By GEORGE CRUDEN, A.M. Pp. 231. London: Simpkin, Marshall, and Co. 1889.—*Manual of Swedish Drill (based on Ling's System), for Teachers and Students.* Compiled and arranged by G. L. MÉLIO. Pp. 79. London: Sampson Low and Co. 1889.—The first of these works has been drawn up by an advocate in Aberdeen, chiefly for the use of teachers in public schools, with a view to promote the physical training of the young. It consists of two parts, the first including marching drill and those exercises in which little or no apparatus is used, and the second those requiring special apparatus, such as is to be found in ordinary gymnasia. The first division has a musical accompaniment for each set of exercises, and both divisions are illustrated by figures showing the manner in which the different exercises are to be performed. It is very much on the principle of Alexander's "Modern Gymnastics," and we have no doubt will be found a useful handbook for teachers. It is evidently the work of a man who thoroughly understands the subject and is careful in his directions. The second work gives a brief biographical sketch of Ling, the inventor of the Swedish system of gymnastics, and full instructions for executing correctly the various movements comprised in his system. It is entirely confined to exercises without apparatus of any description, such as clubs, dumb-bells, and wands, and the use of music is forbidden. At the end of the book a course of ten lessons is given, with the movements illustrated by figures. The system seems one well adapted for introduction into ladies' schools, and might also be adopted with advantage for young and delicate children. If carried out systematically it could not fail to be beneficial.

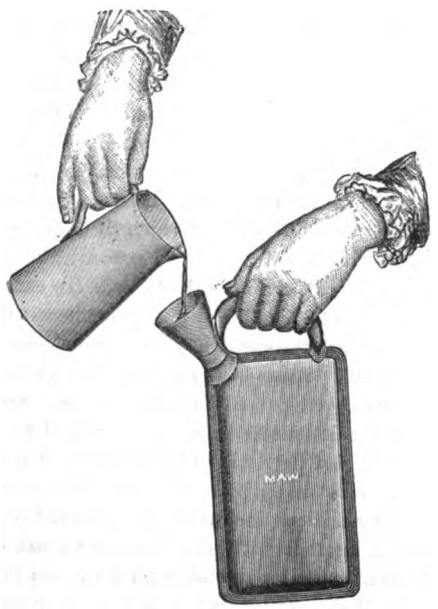
Emergency Notes: What to do in Accidents and Sudden Illness until the Doctor comes. By G. R. BUTLER, M.D. Pp. 102. New York and London: Funk and Douglas. 1889.—This addition to the literature of first aid to sick and wounded does not seem to have anything very new or special on the subject. It gives the usual information respecting what should be done in accidents, in cases of drowning and of poisoning. The book has the advantage of a copious index.

The Gulstonian Lectures on Secondary Degenerations of the Spinal Cord. Delivered at the Royal College of Physicians, March, 1889. By HOWARD H. TOOTH, M.D., F.R.C.P. London: J. & A. Churchill. 1889.—Some slight conception of the remarkable advances made of recent years in the knowledge of the minuter anatomy and physiology of the central nervous system may be gained from the perusal of Dr. Tooth's Gulstonian lectures. The topic selected appears at first sight to be comparatively limited; but it will be found that the lectures are full of facts gained by assiduous and patient study of the histological changes in degeneration of the nerve fibres and the various tracts in the cord selected by ascending and descending lesions. Dr. Tooth has made an important contribution to the scientific study of a difficult subject.

The Causes and Treatment of Abortion. By ROBERT REID RENTOUL, M.D. Edinburgh and London: Young J. Pentland. 1889.—This is a prize essay, with revisions and additions. It is a laborious compilation, and must be the result of careful reading. In the desire to be exhaustive the author has, especially in the chapter on "Maternal Causes," enumerated many important branches of the subject without much discussion. The chapter on the sequelæ of abortion (perimetritis, parametritis, phlegmasia, &c.), having no special characters in the case of abortion, might, in our opinion, have been omitted. Authorities are collected in a short index, but references in the text to chapter and verse would have enhanced the value of the work.

New Inventions.

"COMBINAIRE."



MR. THOS. STOWARD has patented a material produced by the union of indiarubber tissue and felt, to which he gives the name of Combinaire. It appears to be well adapted to many useful purposes, among which the inventor enumerates the lining of horse-boxes or stables and the making of cushions for public conveyances. For the former it appears to be well adapted, being seemingly singularly free from liability to burst under the impact of a sharp blow, and presenting a surface that can easily be cleansed by washing, while at the same time it can be made to afford any required degree of softness and resiliency. For use as a cushion it is of prime importance that a material should be impervious to dust and moisture, especially when seats have to be cushioned which are sometimes exposed—as is the case with railway carriages, omnibuses, and, to some extent, perhaps, with all public conveyances—to showers of rain. We have accordingly subjected a small cushion supplied by the inventor to a very severe test in this respect. The

Digitized by Google

cushion before the experiment weighed six ounces, and was first immersed in water for a period of seven hours. It was found to have absorbed no more than a quarter of an ounce of water. Subsequently it was kneaded under water until it ceased to give off air. Very little air in all was given off, and again it was found to have taken up less than half an ounce of water. After being cut open it readily absorbed fourteen ounces of water. We have the satisfaction, therefore, of saying that, so far as the qualities of this new material can be ascertained by experimental tests, they appear to fit it admirably for the purposes for which it has been designed.

IMPROVED HOT-WATER BAG.

MESSRS. MAW, SON, and THOMPSON, of Aldersgate-street, have submitted to our inspection a Hot-water Indiarubber Bag, the pattern of which exhibits a distinct improvement on the ordinary arrangement in apparatus of this kind. This improvement consists in the funnel for filling the bag being placed at one corner instead of in the centre. The difficulty hitherto felt in charging the hot-water bags is, in

the pattern under notice, removed, as the handle is of sufficient strength and rigidity to allow of its being held by one hand whilst the vessel is being filled by the other, and that without the risk of being scalded by the steam of the hot water. The sample forwarded to us is also provided with a plush cover or jacket, which will necessarily enhance the comfort attending the use of the bag.

THE DETECTION OF COLOUR-BLINDNESS.

To the Editors of THE LANCET.

SIRS,—The subject of colour-blindness seems to be occupying considerable attention at the present time, but few seem to be aware of the imperfections of the tests used by the different railway companies. I will not deal with tests which are manifestly useless, but confine myself to that test which is recommended by many as an efficient one. I mean Holmgren's wool test. At an early period in my experiments in colour-blindness I found that there were very grave objections to this test, from a practical as well as from a theoretical point of view. I will confine myself to the practical aspect of the test.

1. Whom are we to reject by this test? If we reject all the (so-called) partially red and green blind, we shall reject many persons who are practically competent. If we only reject the (so-called) completely red or green colour-blind, we shall allow many persons who are dangerously colour-blind to officiate as signalmen. The test is more theoretical than practical, the main object of testing for colour-blindness being apparently lost sight of. Thus it has to be proved that a man who puts a confusion colour with a green wool cannot distinguish between a red and a green light. Then when a man has put a confusion colour with a green wool, there is still the point to be decided whether he has been judging more by shade than by colour. To an uneducated man a light green and a light greenish-grey are very much alike. In my experience, an ignorant four unit colour-blind—that is, a person who is partially colour-blind, but not colour-blind to an extent necessitating his rejection—is more likely to fail than an educated two unit—red-green colour-blind.

2. A person with central scotoma will escape detection if examined by this test. For example, I examined a person with central scotoma with my pocket colour test (in which small pieces of coloured material are ranged in rows), and found him perfectly colour-blind with respect to red, green, and grey. I then examined him with Holmgren's test, and he went through it correctly with the greatest ease. As a light at a distance occupies the central portion of the field of vision, these persons will be found to recognise colours when close to them, but not when they are at a distance.

3. The red end of the spectrum may be considerably shortened, so much so that a person may scarcely be able to distinguish red from black. It is obvious that this will not prevent him from matching a light green wool with other green wools.

4. The test, being based on a fallacious theory instead of upon practical observations, repeats all the errors of this theory. Some of the features of the test are really due to impurities in the colours used.

With regard to the test which should be used. If the persons to be tested have to distinguish between the standard red and green lights, these lights should be used as a basis of the test; because if any other test were used we should still have the same problem before us from a practical point of view. Space will not permit me to go into the details of my test. Briefly, I put the person to be tested in as nearly as possible the same conditions as he would be likely to be in when following his employment.

Thus, in combination with coloured glasses, I used special kinds of neutral glass of different degrees of thickness. These glasses obstruct the light in the same way that the atmosphere or fog does, and therefore puts the examinee in a similar position to that in which he would be likely to be. It is perfectly certain that a colour-blind person cannot judge by the intensity of a colour when there is a thick neutral glass in front of it. Naming colours is certainly the best method under these circumstances, because it is the expression of the idea present in the examinee's mind. Ignorance of colours would be quite as fatal as colour-blindness if a sailor *thought* a red light was called green and steered as directed for a green light. I think the argument that Holmgren uses against naming colours is really one in favour of it. Thus, many uneducated men who would put a light greenish-grey wool with a light green wool would not make this mistake if told to pick out all the greens.

With regard to the person who should conduct the examination for colour-blindness. There seems to me no doubt that the testing should be conducted by a medical man specially trained in colour-blindness. Testing for colour-blindness is not an easy matter, and requires as much experience as using an ophthalmoscope or stethoscope. I am strongly of opinion that we shall make no real advance until a committee is appointed to report on the subject, and to examine and appoint properly trained examiners. I know of one case in which the examiner himself was colour-blind.

I hope that colour-blindness in connexion with railways will be considered before some great railway accident draws universal attention to the subject and the worthlessness of the tests in use.

I am, Sirs, yours faithfully,

F. W. EDRIDGE-GREEN, M.D.

Finsbury Park, N., Oct. 12th, 1889.

UNIVERSITY OF CAMBRIDGE.—Professor Michael Foster has been reappointed a manager of the Balfour Fund for a period of five years.

THE LANCET.

LONDON: SATURDAY, OCTOBER 19, 1889.

NOTWITHSTANDING the readiness of all classes and companies to laud and magnify the profession of medicine, it is admitted on all hands that it is an underpaid profession. Often the medical man goes unpaid altogether or is paid last of all creditors. And in regard to large sections of the community a most immoral conception of obligation for medical service obtains. The great working and wage-earning class contains comparatively few members who think it proper to provide for themselves and their families a medical man to whom they can honestly and boldly go at any hour of the night or day. Even for ordinary ailments they rush off to the nearest hospital or dispensary, and *a fortiori* for anything extraordinary. Unfortunately this contagion of dependence and pauperism in medical matters has invaded the lower middle and trading classes, and well-to-do people think it quite within their rights to take themselves and their children to the great out-patient departments of our hospitals, and wait for hours in the most promiscuous of all crowds till they are seen by one of the out-patient staff. In the middle of the night when pain presses, at the evening time when matters look threatening, and a certificate of death may be needed to stave off an inquest, the general practitioner is called in, not to save life, but to cover the death of the patient with the semblance of proper attention. In this way several evils have arisen: the wage-earning class and the lower trading and middle classes have become a charge on charities that were never meant to bear such a burden. The medical practitioner who cannot be dispensed with altogether is treated, not as an educated man whom it is an advantage to have as a neighbour and a friend, but as a stop-gap. There is yet a third evil—that the classes who thus escape a reasonable expenditure on medicine are demoralised. Health, which costs them nothing to keep or recover, or but the price of a glass of beer, is lightly esteemed. They are seen in their illnesses or ailments by strangers, who have no social knowledge of them or personal interest in them, and, as they get medicine and advice for nothing, they conceive the idea of getting most other things for nothing. From the medical charity experience they lapse readily into dependence on other forms of charity, and are apt to land as paupers in the Poor-law dispensaries. It is unquestionably true that many a working man who could pay easily £2 or £3 a year to a neighbouring practitioner, and who would blush to get parish medical assistance for himself, thinks it no shame to get hospital advice and medicine for nothing or for a pittance, which is almost more demoralising.

The facility for getting hospital advice and medicine is felt on all sides to be a great evil. Some say that it is quietly encouraged, or at least winked at, by the staffs of hospitals, either in the interest of medical education or for more personal reasons. Dr. RENTOUL says in one of his papers: "A number of practitioners acting on hospital staffs will oppose all efforts to restrict the giving of charity to all, as they hope that, the pay system being introduced, they will receive wages for work done by them." Sometimes the wealthy members of a hospital staff recommend the admission of a private patient rather than take a fee which the patient could easily pay to another surgeon, but which is beneath the dignity of the surgeon he first consults. This is a monstrous evil and an injustice to hospitals and to younger surgeons.

The enormous scale of hospital and dispensary abuse leads to the suggestion of many remedies, some of them, we fear, impracticable, or inadequate, or both. Dr. HUNTER of Paisley proposes to ask the Medical Council to request Government to legislate so that hospitals and medical aid may be paid for by a rate or tax, and a civil medical service for the benefit of the people be organised, the same as is afforded to the army and navy. This is a bold proposal—to ask the Government to pay and appoint the medical attendants of the people, even well-to-do people, who, according to the scheme, have to pay extra. The Government seems to us to have a great many things to do before it will find time to create a civil medical service. Dr. RENTOUL has another remedy—first, the cure of hospital abuses; and, secondly, the elaboration of a medical tariff for all wage-earners making from 20*s.* to 45*s.* a week, including everything, from a visit to an operation for strangulated hernia, for which £1 is to be paid. We think Dr. RENTOUL will do well to concentrate his attention on the removal of hospital abuses. He cannot force the working man to have his operation for hernia done outside a hospital, nor the capable surgeon who does it to be content with 20*s.* There is no power known to the law or to reason for enforcing such elaborate schemes and tariffs. They would shackle medical men in their hard competition with hospitals, and they cannot be enforced. A mere wage-test, too, is very deceptive. One working man with a healthy family and continuous work may be richer with 20*s.* a week than another with 45*s.* Another great defect in Dr. RENTOUL'S plan is, it makes no provision for attendance on families. If the people are to be weaned from hospitals and dispensaries it must be by methods that interest and benefit the families of the working classes, and gives them the sense of having a family doctor who takes a continuous and personal interest in them. Dr. RENTOUL'S scheme, too, includes payments to chemists for medicines, as well as to the medical man for advice. This is a matter for men of experience to determine, but we should say it is vain to expect the wage-earning class to make two payments. The doctor must either dispense or pay the chemist for dispensing. We may return to this subject, but we must, above all things, be practical, if we are to do any good.

THE question of treatment of extra-uterine gestation is too large to be dealt with briefly, but it may be well to indicate what we believe to be the proper procedure under several of the many conditions.

1. Before rupture—i.e., in the first ten to fourteen weeks. Here the difficulty is mainly one of diagnosis, and before diagnosis can be entertained suspicion must precede. It may be safely said that he who has not got the idea of tubal gestation well established in his mind will never

Digitized by Google

suspect these cases, for they do not strike the attention. That they are more frequently suspected now than formerly is due to the greatly increased interest which is now excited in the subject—the increase of interest in its turn being due to increased surgical interference, and this again depending on the great improvement of abdominal surgery. But if the diagnosis of uterine pregnancy at a corresponding period is confessedly most uncertain, much less certain is that of extra-uterine pregnancy; and yet it must be made, or at least approached, nearly enough to justify treatment, either by action or inaction. In this connexion it is most helpful to remember that the difficulties in the diagnosis of extra-uterine pregnancy differ according to the different stages of pregnancy; in the early months it is easy to diagnose that a mass is extra-uterine, but difficult to determine that it is due to pregnancy; in the later months it is easy to diagnose pregnancy, but often difficult to diagnose that it is extra-uterine. The diagnosis of tubal pregnancy before rupture being thus necessarily obscure, what amount of probability may we expect to get? We should carefully inquire into the history of the last lying-in, especially with regard to the question of pelvic inflammation; we should ascertain the dates of antecedent pregnancies, especially with regard to the prolongation of the interval between the last pregnancy and the present supposed pregnancy, as compared with former intervals. We should go into the history of recent menstruation, and not be content with general statements, for strict amenorrhœa is not the rule in extra-uterine pregnancy; it is commoner for the patient to go a week or two over her first or second period, and then to have irregular discharges of blood. There may or may not be mammary signs; but these cases commonly concern multiparæ, in whom mammary signs are both less plain and less trustworthy. Serous secretion in one or both breasts may be taken for what it is worth. The discharge of a decidua is a sign of great importance. It is discharged at very variable times, often in connexion with rupture. It is generally lost unless a strict watch is kept on all discharges. If complete, and if empty, it is absolutely diagnostic of abnormal pregnancy, either extra-uterine or connected with a double uterus; but it must not be forgotten that largish sheets of decidua vera may be discharged from a pregnant uterus without abortion. The diagnosis, so far as it is possible, is completed by pelvic exploration. At this stage the uterus is often not palpably enlarged, the cervix is not usually soft, and all that is found is a lump, generally in one or other posterior quarter of the pelvis, displacing the uterus more or less to the opposite anterior quarter. It must not, however, be forgotten that fatal hæmorrhage has occurred from a gestation scarcely larger than a nut, and which could hardly have been detected. This completes our means of judging. It may be added that all these may be present, and be simply misleading; and yet if all are present we must decide on action or inaction. It is for these cases that electrolysis has been recommended, and it is claimed, especially in America, that in many cases the embryo has been killed, the sac has shrivelled, and all has ended happily. A contrast has been drawn between the diffident diagnosis of surgeons familiar with abdominal section and the confident diagnosis of those who do not operate and have, therefore, few opportunities of testing their correctness. Indeed, the acceptance of their diagnosis has been made almost a personal matter by some electrolists. With all respect for the perfect good faith of these gentlemen, we believe that evidence of such occurrences is entirely untrustworthy. It is known that electricity may flay a fœtus alive without killing it, and when we add that some of these cases may be read side by side with others in which after the use of electricity an ovum has been passed *per vias naturales*, and the operator asks his readers to believe, not that he has innocently procured a common abortion, but that he has induced the fœtus to pass from the tube into the uterus, we feel pained to think that so touching an appeal should fall in such unbelieving times as the end of the nineteenth century. What, then, is to be done? In our opinion, abdominal section.

2. The tube has ruptured. Here two conditions at least may obtain: (*a*) the patient is accessible at the time, (*b*) the patient is not accessible till some time after. (*a*) If the patient is accessible at the time abdominal section should be performed, for she may bleed to death, and the general rules of surgery are current here as elsewhere. (*b*) The patient is not accessible till some time after. We feel bound to warn our readers that this includes the great majority of cases which have been operated on, and that it is quite certain that rupture occurs not unfrequently without a fatal issue. If this is so, it is claiming too much to assert that all patients who do not die after operation have had their lives saved. What is to be done? Here there can be no absolute rule, but in most cases we think that the wisest course is to keep the patient under careful and immediate observation. If the lump shrivels, leave it alone; it has died, and at this early stage will be almost or altogether absorbed in many instances. If it grows, or if fresh symptoms of rupture occur, operate. Should the sac become infected from the bowel, it must be treated according to the rules of fetid abscesses.

3. Supposing that the case is not seen till the later months of pregnancy. What is to be done? Here comes in the question of the life of the child. In our opinion, in the face of the tremendous maternal risks, it is bad sentiment, bad morality, and bad surgery to regard the life of the fœtus for a moment. It should be removed, the operator remembering that many cases are subperitoneal, and should not be attacked in the middle line. If the sac can be extirpated, so much the better; if not, the placenta must be left, and the sac drained. It has been proposed to cut off the cord short and close the wound; but this has not gone beyond the stage of proposal. We shall watch with great interest for reports of such proceedings, whether favourable or unfavourable. An operator who decides to open the abdomen under these conditions must remember that the placenta is sometimes planted on the anterior abdominal wall, and that there is no case on record in which an operator, having fairly encountered it in his incision, has succeeded in stopping the bleeding. We feel bound to add this, because the fear of hæmorrhage has been ridiculed as a bugbear. The position of the placenta in these cases may sometimes be determined by palpation, but not by the (incorrectly named) "placental souffle," which has nothing whatever to do with the placenta, and

Digitized by Google

in all carefully observed cases has been found to be absent over its site.

What we wish principally to inculcate here is the direction in which facts are required. The affection is far from uncommon, and it may be in the power of any of our readers to render incalculable service to knowledge by bearing the main facts in mind, and watching. The discussion of the subject has been somewhat burning in many quarters. It is, above all things, desirable that personalities should be strictly avoided. The affection is common property, and no one who is worthy to fill the humblest place in our profession can do otherwise than rejoice at any advance either in knowledge or in method by whomsoever made, and condole with any colleague who records failures which may contribute to the successes of others, and to record which requires some unselfishness, as well as faith in the good feeling of his professional brethren.

COINCIDENTLY with the remarkable decline in the recorded mortality from scarlet fever in recent years has occurred an equally remarkable increase in the recorded mortality from diphtheria. These changes have been especially noticeable in London. Thus, while the death-rate from scarlet fever during 1888 in Registration London was 29 per cent. below the mean rate in the ten preceding years, the rate from diphtheria exceeded the same average by 23 per cent. And from another point of view it appears that in the ten years 1861–70 the mortality from diphtheria was less than a sixth of that from scarlet fever, and in the next ten years, 1871–80, it was little more than a fifth; whereas since the beginning of 1885 the mortality from diphtheria in London has actually exceeded that from scarlet fever. This increased mortality from diphtheria coincident with a decreased mortality from scarlet fever is noticeable in the mortality statistics for the whole of England and Wales, but is not so well-marked as it is in the London statistics. This is partly due to the fact that both the decline in the mortality from scarlet fever and the increase in the mortality from diphtheria have been much greater in the large towns than in the rest of England and Wales. It is not our purpose now to consider the possibility of any direct relation between the decline of scarlet fever and the increase of diphtheria, but rather to call attention to the serious increase of fatal diphtheria in our large towns, and especially in London, which is not receiving the notice it calls for. In the Registrar-General's reports diphtheria was classed under the same heading as scarlet fever until the year 1859, when the two diseases were first shown separately. Diphtheria mortality in London was high during the six years 1859–64, and showed a mean annual rate of 239 per million of the estimated population; the rate fell to 135 per million in the next six years, and further to 122 in the ten following years, 1871–80. Since 1880, however, the disease has shown a marked increase of mortality, and the mean annual rate in London in the eight years 1881–88 rose to 228, the highest rate being 305 in 1888, which exceeded the rate in any previous year on record. The increase, moreover, has been more than maintained during the present year, for the annual rate during the first nine months of this year was 351 per million, against but 163 from scarlet fever. The distribution of fatal diphtheria within the metropolitan area is very general, but the death-rate from the disease during the three months ending with September last (when 456 deaths from diphtheria occurred among the London population) was most marked in Paddington, Kensington, Shoreditch, Bethnal Green, St. George-in-the-East, Stepney, Newington, and Lambeth. Nearly twelve months ago the continual increase in the mortality from diphtheria in London was brought to the notice of the Local Government Board, and the Metropolitan Asylums Board was authorised to receive cases of this disease for isolation and treatment in their hospitals. It is still too early to attempt to judge of the effect of this hospital isolation upon the prevalence of diphtheria and upon its mortality. We know, however, that in spite of this action the fatal prevalence of the disease has continued to increase. It is not without interest, moreover, to consider both the amount and the proportion of the metropolitan cases of diphtheria that have been treated in the Metropolitan Asylums Hospitals during the last twelve months. It appears that 582 cases of diphtheria were admitted to these hospitals prior to the end of September last, of which 216 proved fatal, 244 were discharged recovered, and 122 remained under treatment on Saturday, Sept. 28th. The proportion of mortality among the 460 completed cases was equal to 47 per cent. When we consider that this rate of mortality is nearly five times that which prevails among the cases of scarlet fever treated in the same hospitals, it is natural to feel a strong desire to compare these with other case-mortality figures relating to diphtheria. Such case-mortality figures, calculated on a sufficiently large basis, are not, however, readily available, and we must wait before we pronounce upon the effect of hospital treatment upon the mortality of this disease. It remains to consider the probable proportion of the London cases of diphtheria treated in the Metropolitan Asylums Hospitals during the past year. We find that of the 1600 deaths from this disease registered in London during the year ending with September last, 216, or 13·5 per cent., were recorded in these hospitals, while the proportion of the deaths from scarlet fever so recorded was equal to 43 per cent. On the somewhat doubtful hypothesis that the proportional case-mortality is the same in and out of hospital, we may therefore assume that during the last year certainly less than a seventh of the cases of diphtheria in London were treated in the Metropolitan Asylums Hospitals, although the proportion has recently been increasing. It remains to be seen what effect upon this proportion of isolation will be produced by the operation of the new Notification Act.

IN a short communication made to the *Nineteenth Century*, Dr. W. COLLIER raises the question of the Comparative Insensibility of Animals to Pain. There is much to be said on both sides of the question. Taking the human race, where the means of determining the relative degree of pain on the infliction of injury are accessible, it is certain that very great differences of sensitiveness exist. Few things constitute a sharper stimulus to a nerve than the knife, though laceration and bruising sometimes are nearly as severe, as those who have had a tooth drawn are well aware. Yet even the pain produced by the knife is borne with a difference, not only by different races, but by different individuals of the same race. Pain which causes

Digitized by Google

one man to faint, will be borne by another without blenching, and there would even seem to be variations in the capability of bearing certain kinds of injury; for whilst negroes will batter each other's heads with blows that would probably prove fatal to a European, but which does them, partly on account of their thick hair and dense skull little harm, yet a blow on the abdomen, or even it is said a cut with a cane, which would cause little more than temporary inconvenience to the European, is seriously depressing or even fatal to them. We may reasonably conclude that if such great variations exist in the human subject they would be still more apparent in animals. That animals are conscious of pain there can be little doubt; nor can we doubt that there are great differences in the susceptibility to pain in different animals. The touch of a whip which will make a dog howl, and a thoroughbred horse to quicken his pace, will apparently be unfelt by an ass. Again, some animals seem to be susceptible to acute pain in certain parts, while they scarcely feel pain in others. A horse or cow will soon feed after a fracture of the leg, but an attack of colic or of peritonitis at once prostrates them, causes them to emit cries and groans, and entirely takes away the disposition for food. That some of the insensibility of the lower races of mankind is due to a much reduced number of sensory nerves seems to have been proved by late researches, but we are not aware that any observations have been made on the relative number of nerve fibres in the nerves of animals as compared with man, though such a research would unquestionably be very interesting. It is often thought that muscular movements show that pain is experienced, but every physiologist is well aware that violent movements can be excited having a tendency to withdraw the part irritated from the cause of irritation without the least perception of pain on the part of the animal. This is most conspicuous where the spinal cord is divided; the contact of a hot spoon with the sole of the foot will cause the leg to be violently drawn up, though neither in animals nor in man is there under such circumstances the slightest consciousness of pain. Cries again afford little information in regard to the endurance of pain, and indeed seem rather to be associated with the emotion of fear, as is shown by the circumstance that many animals caught in a trap will utter no sound, though severely lacerated, whilst they immediately emit cries on the appearance of the hunter. Dr. COLLIER adopts this view, and argues, we think, very strongly in favour of it. He points out that amongst the lower races of men the insensibility to pain is extreme, and refers to an example given in the *Spectator* a few months ago, when a correspondent related the fact that on the introduction of boots into New Zealand the vanity of the natives was so great that when one of them was happy enough to become the possessor of a pair, and found that they were too small, he did not hesitate to chop off a toe or two, stanch the bleeding by covering the stump with a little hemp, and then force the feet into the boots. Dr. COLLIER points out that animals are not liable to shock, and hence after the severest injuries will continue to feed as though nothing had happened; that many animals, as crabs, will throw off an offending limb; and that most animals die in deadly conflict or under the occurrence of sudden wounds, when evidence derived from man shows that little or no pain is experienced. Mr. ROWELL has accumulated in his "Essay on the Beneficent Distribution of the Sense of Pain" a series of remarkable cases, showing the very low sensibility of even the higher animals. He gives, for example, the case of a post-horse, which was running between Botley and Evesham, when it came down with such violence that the skin and sinews of both the fore fetlock joints were so cut that on its rising the bones came through the skin and the feet turned up at the back of the legs, the animal walking on the ends of the leg bones. It was placed in a field till permission was obtained for having it shot, and the next morning it was found quietly grazing, with the feet and skin forced some distance up the leg bones. Dormice, rats, and even monkeys will nibble away their own tails, and an old hyæna kept in the Jardin des Plantes at Paris had its leg broken, and one night bit off the leg at the broken part and ate it. It must be remembered, too, as Mr. ROWELL has pointed out, that pain has its beneficial aspect, being a guard against injury and a check to excesses; the high sensitiveness of the lips in man, for example, preventing the introduction into the stomach of food or fluids at too high a temperature, and the pain of pleurisy or of pericarditis preventing the sufferer from taking any violent exercise. We are quite in accord, however, with Dr. COLLIER, in thinking that a belief in the small amount of pain experienced by animals should not make us less careful in our dealings with them, but should strengthen our belief in the mercy and benevolence of the Creator, and should increase our pleasure in studying their habits and movements.

Annotations.

"Ne quid nimis."

THE SIGNIFICANCE OF THE QUALIFICATION OF L.S.A. PROCURED SINCE 1886.

WE publish in another column a communication furnished us by Mr. Upton, the respected solicitor of the Society of Apothecaries. It is meant to define exactly the legal significance of the licence of the Apothecaries' Society since and under the Act of 1886. Prior to the passing of that Act an apothecary was qualified to practise only in medicine. The licence did not cover the practice of surgery or midwifery. In truth, there was no examination in surgery. Now, however, all that is altered in accordance with those provisions of the Act of 1886 which required—first, that no person should after a certain date be registered in the Medical Register who was not possessed of a qualification in medicine, surgery, and midwifery; and, secondly, that the Medical Council should appoint examiners to assist in and complete the examination of any corporation which, after due endeavours, had failed to combine with any other corporation; so that henceforth its examination should be a test in the three branches of medical practice, and its licence should cover all the three branches. The Society of Apothecaries, and the sister Society in Ireland both took advantage of these provisions, and so saved themselves as qualifying bodies. This is the meaning of Mr. Upton's letter. There is no change in the letters L.S.A. in the qualification column of the Register, following the names of those possessed only of this diploma; but the letters of the title acquired since the Act of 1886 came into force have a threefold signification, and imply as much qualification as the law requires.

SURGEON-GENERAL MARSTON, C.B.

THE *Gazette* of the 15th inst. intimated the retirement from the active list of the Army Medical Staff of Surgeon-General Marston, C.B. During the last thirty years Dr. Marston has done good and meritorious service as an army medical officer, and has filled with distinction several important appointments. In 1873, while employed at headquarters, he drew up all the details connected with the fitting up of the *Victor Emmanuel* hospital ship for service with the expedition to Ashanti, with most satisfactory results. In 1877, as medical member of a committee appointed by the Secretary of State for War, he drew up the dietary for military prisons which is now in general use. In December of that year he was appointed secretary to the Principal Medical Officer of the British Forces in India, in which capacity he had to prepare the scheme of field hospital organisation which proved so successful in the Afghan wars. He was also member of a committee appointed to consider the steps to be taken for the withdrawal of the troops from Afghanistan after the treaty of Gundamak, in consequence of cholera having made its appearance on the Cabul-Khyber route. For these services he was favourably mentioned in general orders, and was appointed honorary surgeon to the Viceroy. In 1882 he was appointed sanitary officer to the Egyptian Expedition, was present at the battle of Tel-el-Kebir, and was promoted to the rank of Deputy Surgeon-General. He subsequently held the appointment of Head of the Statistical and Sanitary branches at the Army Medical Board, and was nominated a member of the commission appointed to inquire into the education afforded by the Queen's Colleges in Ireland. In 1887, at a very short notice, he delivered a course of lectures on Military Hygiene to the probationers and medical officers at the Army Medical School at Netley, during the illness of Professor De Chaumont. In the autumn of the same year he was sent by the War Minister as the Army medical delegate to the ninth International Medical Congress held at Washington. His valuable report of the proceedings was published as an official document by the Government (*vide* THE LANCET, March 17th, 1888). In 1888 he was sent to Egypt as Principal Medical Officer of the British forces serving there, and organised the medical arrangements connected with the contingent sent to Suakim under Sir F. Grenfell. On his promotion to the rank of surgeon-general, he was transferred to Gibraltar, from which he has returned to retire from the service. In addition to much useful official work, Dr. Marston has contributed some excellent papers to the Army Medical Department Reports. Of these we would only specify a Report on the Fevers of the Mediterranean, in the volume for 1861; on Cerebro-spinal Meningitis, 1866; on Cholera, 1878; Enteric Fever, 1879; Sanitary Report of the Egyptian Expeditionary Force, 1881; and in 1884 a description of huts designed by him for Suakim and hot climates. We cannot but think that the Army Medical Service has sustained a great loss in Dr. Marston's retirement, but we trust it may be a gain to the profession by enabling him to turn to good account the experience he has gathered in his varied service.

DEATHS UNDER CHLOROFORM.

AT an inquest recently held the particulars were given of the death of a child aged six years, who succumbed to chloroform at the Victoria Hospital for Children. The child was admitted for treatment of disease affecting the left hip-joint. He had taken chloroform successfully upon two previous occasions, but on the day upon which the operation was to be performed the boy died, after having inhaled the anæsthetic for fifteen minutes. A post-mortem examination was held, and the medical officer is reported to have said that there was fatty degeneration of the heart, liver, spleen, and kidneys. The above record illustrates the fallacy of two popular beliefs—first, that a person who can take chloroform with impunity upon one occasion will subsequently enjoy an immunity from danger; and, secondly, that children, who proverbially take chloroform so well, are less liable to fatal accidents from its effects than are adults. In the case in question the open method appears to have been adopted, and a careful watch kept upon the child's respiration and pulse; but in spite of this, respiration and cardiac action stopped, and although means of resuscitation were adopted they failed to save the boy's life. Visceral degeneration is so commonly associated with chronic joint and bone disease that it is preferable, we think, in anæsthetising a child having such a malady to select either a mixture of ether and chloroform, or employ ether in succession to nitrous oxide gas. As was shown years ago by Pollock and Warrington Haward, the youngest children take ether well when that agent is properly manipulated. With regard to prolonged operations upon very young children, the chilling effects of ether vapour is a decided drawback to its use, but to meet our requirements in these cases we have the mixtures upon which to fall back. Even when nitrous oxide cannot be given, and the child struggles against ether, a few inspirations of a dilute chloroform vapour will lessen the irritability of the fauces and larynx, and allow the subsequent exhibition of ether without difficulty. There have now been so many deaths of children attributable to chloroform, that it seems time the anæsthetic in question should not continue to occupy the position it has hitherto held of being the routine agent of producing anæsthesia in young people.

Almost before the ink is dry with which we record the above fatality, the report arrives of the death of a woman in a Dublin hospital to whom it was proposed to administer chloroform as a preliminary to amputation of a thumb. It appears before she was fully anæsthetised she collapsed and died. The jury's finding that "the deceased died from fatty degeneration of the heart" does not carry us very far. There has always been a strange fatality about minor operations conducted under chloroform, so that it is hard to understand why, in a case such as that before us, the anæsthetic selected should be the confessedly more potent and perilous chloroform, rather than ether. The most thoroughgoing opponents of ether recognise that its bad effects, whatever they may be, are only shown when considerable quantities are taken, and the operation is a very prolonged one.

STREET IMPROVEMENTS.

MR. DOUBLEDAY, of the London County Council, has been making an ingenious calculation of the cost of narrow streets, which leads him to some very striking conclusions. For example, he contends that the delay to the vehicular traffic consequent upon the congested state of the Strand represents a money loss at the rate of upwards of £47,000 a year. The novelty and ingenuity of this argument cannot be denied; nor, again, can the soundness of his ultimate conclusion be successfully assailed. But we are not at all equally clear that his immediate inference is altogether irreproachable. Indeed, he appears to us to have lost sight of the fact that widened streets imply extended areas, and consequently that it may well happen that the improvement of such a thoroughfare as the Strand in the way of increasing its breadth may add more to the distance of an average business journey than it deducts from the delay in making it. But if we suggest a doubt as to the soundness of Mr. Doubleday's very plausible argument it is not because we

Digitized by Google

have any desire to resist his conclusion. On the contrary, it seems to us that it would be difficult to overstate the importance of such improvements as he discusses. The excessive traffic through a narrow way which such a thoroughfare as the Strand exhibits is unwholesome both for body and mind. The turmoil and struggle are distressing to the nerves and destructive of serenity. The turbid atmosphere stirred into omnipresent eddies is laden with germ-infected dust, while the narrow and tortuous channel prevents the free circulation of fresh air, and the high buildings shut out the fitful sunlight. These are faults which it is well worth a liberal outlay to correct, and their correction would be an unalloyed and indisputable gain. We think therefore that there are good grounds for carrying out such work as Mr. Doubleday recommends without regard to his perhaps questionable arithmetic, and we are glad to see that the London County Council is addressing itself to this kind of undertaking. We trust that the considerations which have led to the deferment of this topic at the present time will have no more than a temporary application.

HYPNOTISM RETAIL AND WHOLESALE.

HAPPILY for the credit of the profession, the facts of the hypnotic state are pretty widely known and appreciated. A halo of mystery, a spice of the unknown, a faint suspicion of dalliance with occultism, render the so-called science of hypnotism a refreshing and acceptable change to the overwrought mind of the hard-working medical practitioner, and he is not backward to show his appreciation by joining societies at which hypnotic séances are held, or in other ways to keep himself *au courant* with the matter. But he is not always able to see between the lines and sift the science from the chicane. Against alike all the best feelings of humanity and the ethics of professional etiquette are "show exhibitions" of hypnotic phenomena, when the unknowing public are invited to attend upon paying an entrance fee. As well might the operating theatres of our hospitals, or the wards where our hystero-epileptics are treated, be made a focus for public attention, and afternoon receptions given, the proceeds of payment being of course given to "a charitable object." But we reach the climax of undesirability when the "charitable object" be the promoter of the show, whether he call himself "experimental director," "professor," or what not. Hypnotism, if in any way a remedial agent, belongs to the therapeusis of regular practitioners, and so falls within the scope of existing societies, such as the Neurological, Clinical, and Psychological, and so there can be no *raison d'être* for a concern such as is proposed under the aggressive title of the "Magnetic and Hypnotic Society of Great Britain"; and when we state that the "experimental director" has held public performances, we need hardly offer further arguments against a concern which cannot be deserving of the support of scientists or the public.

SALE OF FOOD AND DRUGS ACT.

A VERY trivial error in a certificate given by a public analyst was a few days ago the cause of an unfortunate collapse of proceedings under this Act against a dairyman for the sale of diluted milk. It is, no doubt, well that great circumspection should be used about the infliction of penalties, and it is right that a tradesman accused of infringing the provisions of the statute should have the benefit of carefully devised machinery for protecting him against false charges or the untoward consequences of official mistake. But, precisely on that account, it is the more important that the utmost care should be exercised by public officers and others who have the conduct of proceedings in a matter of this kind to avoid such a mishap as occurred the other day at the Bath City Police-court. A local milk dealer was, as we have said, charged with selling diluted milk, and whatever may have been the merits of the case, his defence was rested upon the narrow ground that the public analyst had entered the name of a Mr. Montague in his certificate as that of the person who had delivered to him the sample for analysis, whereas he should have entered the name of Gosling in this document. Mr. Gosling is Mr. Montague's assistant, and Mr. Montague, having effected the purchase and sealed up a sample of the milk in question, sent it by the hand of Mr. Gosling to the public analyst. For all ordinary purposes, therefore, it would be held that what Mr. Gosling had done in the capacity of agent to Mr. Montague had been done by Mr. Montague himself, and it is clear that the error of inserting Mr. Montague's name in place of Mr. Gosling's did not in the smallest measure affect the merits of the case. Nevertheless, it was held by the magistrates to be a good objection, and the charge was accordingly dismissed. The moral would seem to be that public analysts must be as careful about the formalities of their procedure as about the substance of their analyses.

TUBERCULOSIS.

DR. GREFFIER (*La France Médicale*, Nos. 115 and 116), writing upon recent researches in tuberculosis, alludes to several papers on this subject read at the recent Heidelberg Congress of German Physicians and Naturalists. In the course of a discussion Professor Rindfleisch declared that there were two different bacilli in phthisis, and that he had observed that the bacillus met with in miliary tuberculosis differed in thickness from that found in phthisis. But, as Dr. Heller pointed out, such differences may arise in the same sputa examined at intervals of a few days; and Dr. Greffier is doubtless correct in regarding this notion as insufficient on which to restore the doctrine of duality of phthisis. Dr. Böllinger finds that dilution of the milk of tuberculous cows deprives that fluid of its infective property, whether the dilution be made with water or with the milk from healthy animals. If this be so, then it is a point in favour of obtaining milk from large dairies, and also should check the practice of consuming milk taken from one cow alone, and unmixed with that from others. Yet it was found that not even a dilution of 1 in 100,000 destroyed the virulence of bacillary sputa. The subjects of heredity and contagion in respect to the transmission of phthisis were also discussed. Dr. Aufrecht held that the former was much more important than the latter, and declared that he had never met with, either in hospital attendants or in private practice amongst married persons, a single undoubted example of phthisis being communicated by contagion. On the other hand, Dr. Heller said that cases of phthisis did arise in hospitals; he had seen cases of croupous pneumonia which, instead of resolving, passed into caseation which he attributed to bacillary infection. In the Section of Hygiene, Dr. Sonnenberger, in a paper on the Risks of Bringing up Infants on Cow's Milk, declared that the number of "tuberculous" (*perlières*) cows in certain parts of Germany averaged 60 per cent., and that in Paris the mortality of infants attributable to the consumption of such milk was frightful. Other drawbacks to the use of cow's milk lay in the fact that certain vegetable poisons mingled with the food of the animal may appear in the milk. He especially pointed to the feeding on grains or bye-products of alcoholic fermentation as liable to render milk poisonous and to account for gastro-intestinal catarrhs in children. Dr. Schottelius finds that inhumation of tuberculous viscera does not, even after the lapse of a year and a half, destroy the bacilli or notably impair their virulence.

THE DEATH UNDER NITROUS OXIDE.

THE record of so unusual an event as a fatality under this anæsthetic has, through the medium of the daily press, received a widespread circulation, and has produced much alarm and dread of the gas. Now that the facts are fully known, it becomes our duty to allay what at best are groundless fears, and to remove the slur which rests upon nitrous oxide gas, as well as to reiterate that we believe nitrous oxide to be practically without danger if only patients, as well as administrators of the gas, would take a few simple precautions. The patient whose sad death we recorded in a preceding issue was seventy-one years of age, she was suffering from advanced fatty degeneration of the heart, and was fully aware of her condition. Although she breakfasted at nine in the morning, and the teeth were not removed until noon, digestion appears to have been wholly suspended by the intense terror she experienced at the thought of submitting to the operation. She repeatedly told her daughter that she "knew she would not survive the operation." Added to the full stomach, and the extreme apprehension, both conditions liable to tell against even a healthy, much more a fatty heart, the patient wore a very tight corset, so tightly indeed was she laced that it was found difficult to remove the stays even by slitting up the laces with a knife. Although it would appear the dentist warned the patient to loosen whatever she had on which was tight, she merely loosened the neck wraps, leaving the more important corsets tightly laced. As soon as nitrous oxide was commenced to be inhaled, the dentist noticed that respiration was insufficient, and urged deeper inspiration. Doubtless this weak breathing was due to the tightness of the clothing. When eventually the patient became unconscious, two teeth were removed and a hole drilled into the antrum, giving vent to pent-up secretion. Then the patient suddenly changed colour, became livid, while respiration and heart action ceased, it is believed, simultaneously. During the subsequent performance of artificial respiration the undigested contents of the stomach were voided. There seems little doubt in this case that the impairment of respiration from tight lacing, along with distension of the stomach, told upon a heart itself badly diseased and weakened by the fear to which the patient had given way, and the most melancholy result followed. There can be no question that when any known degeneration of the heart muscle exists the recumbent or semi-recumbent posture should be adopted, as can easily be accomplished in a dental chair, and corsets removed and all waistbands and strings loosened. Where fear exists in the patient's mind, it is important to avoid a full stomach; a cup of beef-tea or a basin of bread-and-milk should form the meal preceding the operation. Reviewing all the circumstances of this most sad fatality, there is, we think, no reason for going back from the position which modern anæsthetists have occupied, that nitrous oxide is not only the safest anæsthetic we possess, but that when it is circumspectly given it is practically free from danger, save in cases of very advanced disease of the heart or lungs.

CONFECTIONERS' DISEASE.

DR. RODIGUEZ MENDEZ, Professor of Hygiene in the Medical Faculty of Barcelona, has just published in a new Spanish journal, *La Medicina Prâctica*, some notes of a case of a peculiar affection of the fingers and nails which appears to have been due to the patient's trade, that of a confectioner. Poncet of Paris, and Albertin of Lyons, have also observed the existence of this affection among those who are engaged in the calling of a confectioner. Dr. Mendez's patient was a man about forty years of age. When seen first every finger on both hands was affected, but not to the same extent. The worst was the middle finger of the right hand; here the anterior part of the nail was thickened and flattened, so that it had the appearance of a spatula, which is one of the signs noted by Albertin as occurring in his cases; the base of the nail was covered by a swollen portion of the soft parts which was not adherent to the nail, and which was of a bright-red colour with fissures as well as ridges on its surface. In it there were a number of minute abscesses, from the openings of which little beads of pus could be made to exude by pressure. The disease was evidently a combination of onychia with paronychia, and it was a remarkable point in the history of the case that the man had suffered in a similar manner, only much less severely, some years before, when he first practised the trade of a confectioner, and that when, for some cause totally unconnected with his malady, he had given up the trade, his fingers quite recovered. After a time he again took to the trade, but was at first engaged in making pastry and arranging the ornaments, during which time his fingers remained quite well. As soon, however, as he began to work on *marrons glacées* and on crystallised fruit his fingers began to become sore just as they had done in former times. There could be no doubt that the affection was due to the immersion of the hands in hot and cold syrups and the rubbing in of sugar, which, according to Remy and Broca, has the property of causing the tissues to become gangrenous. Dr. Mendez suggests that in this way openings were made by which pyogenic micrococci obtained access. His treatment consisted in washing the parts with a boracic lotion and wrapping them in boracic cotton wool. Of course the patient was enjoined to discontinue working at his trade.

ENTERIC FEVER AT BALRANALD, N.S.W.

THIS outbreak, which has been made the subject of a very exhaustive report prepared by Dr. J. Ashburton Thompson, occurred in a small and isolated bush township containing a population of 670, of whom no less than 120 suffered from enteric fever and 15 died. Every consideration calling for investigation is dealt with in detail, and by a process of exclusion water comes at last under grave suspicion; much of the material on which this view is based being the outcome of some very careful investigations made by Dr. G. L. L. Lawson, the district government medical officer. The main water-supply is derived from the considerable river on which the township lies, but rain tanks had recently been filled by the rainfall of January, and at that season of the year these tanks afford a much cooler and more attractive beverage than that supplied by the river. One special tank seemed associated with the outbreak. Amongst 124 persons known to use this tank water, there were attacks at the rate of 33·8 per cent.; amongst the remainder of the population the attacks, which numbered 47, were at the rate of 9·4 per cent. But amongst the latter there occurred a number of secondary attacks, and, quite apart from households known to use the tank water, it was incidentally drunk by other unknown persons, and it was supplied to at least one store where it was kept for customers, and also to two hotels, where it was used in the bars and at table. Under these circumstances, it became very difficult to eliminate all sources of error, and to assign every case occurring during the period preceding the secondary attacks absolutely to the tank water; but the general weight of the evidence is strongly confirmatory of the view taken by Dr. Thompson and Mr. Lawson. As to the means of pollution to which the tank may have been subjected, there was unfortunately but little doubt; and what with neighbouring cesspits, overflows, together with the recent filling up of part of an adjoining basement with earth, and this after the occurrence of several cases of fever

Digitized by Google

in the house, it can hardly be doubted that means existed by which specific poisoning of the tank water can have taken place. Much pains have evidently been bestowed upon the report, and the perusal of it can hardly fail to assist in educating the people as to the extreme danger of allowing any such conditions to prevail in their midst as will subject their domestic water-supplies to the risk of contamination.

THE HOUSING OF THE WORKING CLASSES.

THERE are probably few Acts of Parliament more complex than those which deal with the improvement of the houses occupied by the poorer portion of the community, and this is especially unfortunate, seeing that the constitution of the London County Council gives promise that the existing legal powers for effecting this improvement will be more fully exercised than heretofore. An effort to make these Acts more intelligible is therefore very welcome, and for this reason we have pleasure in calling attention to an admirable little book on the powers of the London County Council in regard to the housing of the working classes, by Mr. William Chance, Barrister-at-law. This work has the advantage of discussing the whole subject with great clearness in the small compass of some sixty pages. Mr. Chance has selected especially as the texts of his argument those provisions which are the most obscure, and thus the reader is able to learn with little trouble the view which an experienced counsel takes of the intentions of the Legislature. There is one point upon which we are disposed to differ from Mr. Chance—viz., the power of the London County Council to exercise, upon the report of its own medical officer of health, the powers which devolve upon it in the event of the default of a vestry or district board to carry out the provisions of Torrens' Acts. We may, perhaps, be misunderstanding him, and he may be assuming that the Council and the vestries and district boards are arranging by agreement for the making of the services of medical officers of health appointed by the former body available in the districts of the latter boards. There is no indication of this at present. We commend the book to all within the metropolitan area interested in the subject, feeling convinced it will serve to relieve them of much of the difficulty that has hitherto stood in the way of a clear conception of the intention and powers of these Acts.

HYPERPYREXIA IN HYSTERIA.

THE *Centralblatt für Klinische Medicin* translates from a Danish medical journal a notice of a case of hysteria with a rise of temperature to 113° occurring in the practice of Dr. Lorentzen. The patient was a nervous woman, who after an attack of hæmoptysis suffered from severe dyspnœa with cyanosis and temporary asphyxia several times during the night; after the attack the patient lost consciousness for some time, and was then anxious and inclined to hallucinations. During the next two months she had, without any signs of phthisis, repeated attacks of hæmoptysis, with a repetition of the symptoms connected with the respiratory organs, added to which there was retention of urine. The temperature varied for three days from 103° to 104° F.; on the fourth day at noon it rose to 113°. Dr. Lorentzen found the patient without any other symptoms of inflammation, but slightly delirious; the temperature an hour afterwards had fallen to 108°, and in the evening it was 106·3°. The next day, after some paroxysms of dyspnœa, the temperature rose again to 113°, but fell in an hour to 99·5°. It varied in the next few days from 101·3° to 103·1°, and then became normal. The author considers the hæmoptysis without the slightest lung affection as neuropathic, and the rise of temperature as hysterical, as there was no organic disease, and the respiratory disturbance was typically hysterical. It may be remarked that Teale found the temperature in a hysterical patient 122°, and Wunderlich 109·4° (*Archiv der Heilkunde*, vol. ccx.).

THE REDRESS OF CHILDREN'S GRIEVANCES.

SOME instructive notes on the working of the Act for Preventing Cruelty to Children are contained in the October number of the *Child's Guardian*. One of the lessons to be learned from these reports is the necessity of coupling with any fine proposed the alternative of imprisonment. A number of the cases dealt with under the Act have been those of children belonging to poor and dissolute parents, to whom any but the smallest payment would be an impossibility. The abuse of child insurance is deservedly exposed. Its evil influence on the death-rate during infancy might be effectively met by applying the remedy here quoted from a contemporary—namely, that any claim should be discharged not in money, but by providing for needful funeral arrangements. There is difficulty in some cases in getting children who have been cruelly treated to give evidence against their oppressors. The testimony of one boy when called as a witness of his father's ill-usage of him proved, either from fear or some filial regard, probably the former, to be a mere tissue of prevarication. In certain cases also magistrates have had some difficulty in applying the Act. Thus a few days ago a question of liability which is vested by the Act in the child's temporary custodian remained unsettled because a bench of magistrates were unable to decide between the responsibility of a father at sea and a mother at hand. Sometimes the *Child's Guardian* is needlessly severe, as, for example, when it refuses to make allowance for errors of ignorance in infant feeding, and critically censures a jury because it showed in this particular a sensible degree of moderation.

OPEN-AIR TRAVEL IN CONSUMPTION.

DR. H. I. BOWDITCH of Boston (*Med. News*, Sept. 28th) read an interesting paper before the American Climatological Association to prove the value of open-air travel "as a curer and preventer of consumption," basing his remarks upon the records of a journey taken in 1808 by his father, then thirty-five years of age, and threatened with that disease—cough, hæmoptysis, anæmia, diarrhœa, general malaise, fever, and debility being the indications. In this state of health he started with a friend on a tour through New England in a one-horse chaise. After the first day's travel—of twenty-five miles—he was so exhausted, and had so much hæmoptysis, that he was advised to return "to die," but he courageously pushed on, and every day brought him improved health. The benefit thus received made him resolve thenceforward to take daily regular open-air exercise; and when in 1838 he died, at the age of sixty-five, from carcinoma of the stomach, one lung presented "evidences of an ancient cicatrix at its apex, both being otherwise normal." Dr. Bowditch also states that his father married his cousin, who died of chronic phthisis in 1834. Of eight children, two died (at the age of eleven and at birth respectively), but all the others are either now living or arrived at adult life and married, and of the ninety-three direct descendants of his father not one is phthisical. This, Dr. Bowditch thinks, must be largely attributed to the above-named journey, and the subsequent careful regulation by his father of his own health and that of his offspring. We may append a few of the practical remarks which Dr. Bowditch deduces from his own family experiences:—"For my own part, I fully believe that many patients now die from want of this open-air treatment. For years I have directed every phthisical patient to walk daily from three to six miles; *never* to stay all day at home unless a *violent storm* be raging. When they are in doubt about going out, owing to

Digitized by Google

'bad weather,' I direct them to '*solve the doubt*, not by staying in the house, but *by going out*.' A cloudy day, or a mild rain, or the coldest weather, should not deter them. If the weather be very cold, let them put on respirators before leaving the house and be thoroughly wrapped in proper clothing for the season. I direct them never to stand still and gossip with friends in the open street, as by so doing they are much more liable to get a chill than while walking. Hence, summer and winter alike, my patients usually get plenty of fresh air uncontaminated in a great part, at least, by the previous breathing of it by themselves or by other occupants of the house. This course, I believe, might be pursued in any part of our common country. I am certain that I know of patients who have become well and able to attend the business of life under this course. May we not also at times send our patients over short distances in open vehicles, instead of thousands of miles off in ill-ventilated cars to an entirely different climate? Have any of us ever sufficiently tried this open-air journeying *at home*, so to speak—that is, in the region of the country where the patient lives, wherever that may be?" There is sound common sense in these words.

STARVING SCHOOL CHILDREN.

THE report prepared by a special subcommittee of the London School Board upon the problem of providing food for the destitute children who are collected in the elementary schools of the metropolis will draw public attention to one of the most valuable channels of philanthropic effort. The work of supplying wholesome food in sufficient quantity to the children of the poor is one that has the merit not only of alleviating present and severe distress, but also of redounding to the future advantage of the recipients and the State. It is quite impossible that starving children can derive any adequate benefit from the instruction provided for them, so that from the point of view of the teacher it is of prime importance that his pupils' hunger should be appeased. Otherwise his labour will be, in large measure, thrown away. But it is not on this ground only, not even on this ground chiefly, that the wisdom of this form of charity is to be vindicated. The privations of childhood are responsible for much of the incurable misery of after-life; and the great principle that "prevention is better than cure" can have no more striking exemplification than is afforded by the sequelæ of an insufficiently nourished childhood. Hence, the benefactions which take the form of providing food for the children of to-day are conferring an incalculable benefit upon the manhood and womanhood of the coming generation. It is, however, made very clear by the committee's report that the vices which commonly attach to unorganised and sporadic effort are abundantly exhibited by the arrangements at present in operation for supplying this need. Thus, after enumerating the principal societies which are doing this work, the report states that "in some districts there is an excess of charitable effort, leading to a wasteful and demoralising distribution of dinners to children who are not in want, while in other places children are starving." It is to be hoped that the state of things thus indicated will not be suffered to continue. The work which these voluntary societies have so worthily commenced is one that, both by its magnitude and delicacy, demands the best efforts of those who undertake its administration. On the other hand, the vast aggregate of 50,000 children who are daily sent to school in want of food presents a problem which by its magnitude rebukes the errors, however venial in themselves, of overlapping activity and disorganised effort which result in the waste of energy and of material, whilst the serious if somewhat insidious danger of pauperising the children and their parents will cause a wise philanthropist to walk very circumspectly in this way. Altogether, therefore, it seems to us that the argument in favour of consolidating the subsisting organisations and placing them under the control of a strong central committee is irresistible, and we hope that the very well considered scheme which has received the subcommittee's endorsement will commend itself to those whose co-operation is necessary to its success.

THE BLOOD IN PHTHISIS AND CANCER.

DR. G. NEUBERT (*La France Méd.*, No. 118, from *St. Petersb. Med. Woch.*, No. 32) has examined the blood in twenty-four cases of phthisis at various stages, and found that in nine the number of corpuscles was normal, in three it was above, and in twelve more or less below, the average. On the whole, there was an average diminution of about 8 per cent. The increase noted in three cases might perhaps be attributed to profuse night sweats. The hæmoglobin showed a reduction to 73 per cent. in the females and 85 per cent. in the males. There was no notable change in the number of leucocytes, but it was observed that multi-enucleated forms predominated. In five cases of cancer of the œsophagus and four of cancer of the stomach there was an invariable diminution in the number of red corpuscles, and also notably of hæmoglobin. It is inferred that the hæmoglobin, being the more "sensitive" element of red corpuscles, is more profoundly affected in cachexia than the stroma of the corpuscles. A distinction was made between the anæmic and marasmic types of cancer, the latter exhibiting an average reduction of 13 per cent. of corpuscles, whilst the hæmoglobin fell to 87 per cent. of the normal; the former showing a corpuscular reduction of 35 per cent.; whilst the hæmoglobin was as much as 70 per cent.

SANITARY WORK IN ISLINGTON.

THE Islington Vestry, on the report of their medical officer of health, Dr. Meymott Tidy, have ordered the demolition of nineteen dwelling-houses in Nelson-place, Holloway, and Aston-buildings, Holloway-road. One vestryman is reported to have said that he had found all the houses thoroughly rotten; not a closet was in repair, and the stench in some of them was fearful; the closets and the cisterns were inside the filthy living rooms. Another vestryman said he was a practical builder, and knew something of the places. Sixteen years ago he had to look at them in the way of business, and then said they could not possibly be put into repair. The brickwork was a complete sponge, and the places were soaked through by every rainstorm; if the lot of them were given him to-morrow, he would pull them down in a week. We are glad to be able to report that the decision of the vestry was unanimous, and this augurs well for the sanitary administration of the parish. It would be well if Acts of Parliament were administered with the same vigour throughout the metropolis.

UNIVERSITY OF SYDNEY.

THE authorities of the University of Sydney are about to endow, with other professorships, a Challis chair of Anatomy. The salary of the new professor will be at the rate of £900 per annum, but without any participation in the lecture fees, which is surely an unwise restriction in the interests of a growing institution. He must devote his whole time to the duties of the office, and will not be allowed to engage in private tuition or practice, or in any profession or business, except with the consent of the Senate, and his salary will commence from the 1st of May next. Applications must be made to the Agent-General for New South Wales before the 19th inst.

SWIMMING AS A PART OF SCHOOL TRAINING

SOME have impeached the administration of the Board of Education on the ground that it offers, practically without cost, instruction in studies which are not essential to the maintenance of an efficient average of national intelligence. Accomplishments, it is argued, not without reason, may be purchased by those who value them without the expenditure of public money. No such objection, we feel certain, could properly be urged against the incorporation of a fairly extensive system of physical exercise into the ordinary school work. True, in its general application, this assertion is particularly true in its reference to the art of swimming. As a form of gymnastic movement, and an aid to cleanliness, it is alike valuable, especially to children attending town schools. As our principal safeguard against the risk of drowning it is simply indispensable. It is, further, most easy to learn, and once learnt is never forgotten. We have therefore observed with much satisfaction a growing tendency not only in Board schools, but in schools generally, to include the teaching of swimming in the regular course of education. The latest advance in this direction is a very decided one taken by the School Board of Aston Manor, Birmingham. It consists in a resolution to erect swimming-baths for the benefit of the scholars, and the project, it appears, has been approved by the Education Department. Into the financial ethics of this new departure we need not enter. In many districts, happily, no such extensive reform would be required in order to secure the end in view. Public baths are to be found in many inland towns, and might at set times be utilised by the school children. For others educated at the coast no such provision is required. What is in every case necessary is that swimming should be recognised in the regular educational course, and taught by competent persons (who might hold some other office besides) to every boy and girl.

DEATHS FROM PARAFFIN LAMPS.

ON the 9th of this month two inquests were held in Liverpool in regard to deaths occasioned by paraffin lamps. In one case the old mistake was made of trying to extinguish the lamp by blowing down the chimney. The mixture of hot air and vapour in the cistern were ignited and a man was burnt to death. In the other case a woman went to sleep with a lamp burning near her bed. It is said that during the night the lamp exploded and set fire to the bedding, and this time also a life was sacrificed. The causes of such accidents and the conditions of danger have repeatedly been explained, but as ignorance is still rife and fatal disasters still occur very frequently, it is necessary from time to time to repeat the lessons. First, then, let it be remembered that petroleum oil — for it is almost certain that foreign petroleum and not the artificially made paraffin oil was used in the lamps—contains naturally a good deal of the light, volatile, and easily exploded oil known commonly as petroleum spirit. An Act of Parliament directs that this spirit shall be properly removed before the oil is sold in shops, and a vigilant supervision should at all times be exercised over the oil offered for sale to the unsuspicious public. But this supervision is too often eluded or neglected; and if the facts are correctly reported there can be no doubt that, at any rate in the second accident, and probably in the first also, the oil used would not have satisfied the Parliamentary test. If the oil had been examined, the "flash point"—that is, the temperature at which a miniature explosion follows the application of a light to the oil—would almost certainly have been found to be too low. The spontaneous explosion of a mineral oil lamp is fortunately not a common although by no means a novel phenomenon. It points unmistakably to the use of an oil the sale of which is dangerous and illegal. As to the other disaster, it is foolish, dangerous, and totally unnecessary to put out a lamp by blowing down the chimney. When the wick is turned down to a certain point, very easily found, the flame flickers and goes out in a minute or two. But the dangers of mineral oil lamps are by no means confined to the two which were illustrated by the late deaths. An oil lamp should never be carried about, and if, as often happens, it be a small and unstable one, it should stand on a safe shelf or table, where there is no chance of its being upset. In the mean time, we commend to the authorities of Liverpool and other towns and villages the importance of a frequent examination of the oil sold in such enormous quantities in the shops. The use of mineral oil has increased rapidly of late, and has brought with it a great boon to the poor as well as the rich. But this renders it only the more necessary that vigilant care should be exercised in regard to its quality. We see that the Birmingham Watch Committee have decided to call the attention of the Home Secretary to the dangers attending the storage of petroleum in shops. They are quite right, but we trust that, pending their petition, they are using the powers they already possess by scrutinising the quality of the oil which is stored.

EPIDEMIC OF PEMPHIGUS.

AN epidemic of pemphigus has recently occurred amongst young children in Brussels, sixteen cases having been treated in the Hospice des Enfants Assistés under the care of Dr. Max. The ages of the subjects varied from two days to thirteen months. The eruption generally affected the thighs and abdomen, sometimes other parts of the surface, but never the palms of the hands or the soles of the feet. Red patches were first seen, and upon these there soon appeared bullæ, varying in size from that of a lentil to that of a walnut. Their number was usually inversely proportional to their size and to their age, and their contents, which were quite clear, did not become purulent except where the general health of the subject was bad. The cases ran a mild course, and were treated by pricking the bullæ and dusting them over with starch powder or subnitrate of bismuth. A starch bath was also given daily. No case of the transference of the affection to an adult was observed, though it has been demonstrated by Vidal and by Colzat that adults can be inoculated successfully from the liquid in the bullæ, and a special bacillus has been described by Gibier.

CHEMISTS AND THE MEDICAL PROFESSION.

THE ancient grumble against the practice of prescribing by chemists has recently been revived in New Zealand, and has followed familiar lines, and elicited the usual arguments in favour of and against the custom. The Medical Association of New Zealand brought forward a Medical Practitioners Bill which, amongst other things, provides for the imposition of a heavy fine upon anyone who, not being a registered medical practitioner, "practises for gain or uses the designation 'consultant.'" Matters were not improved when, in reply to remonstrances from the pharmacists, it was explained that the Bill was mainly directed against "quacks." So long as general practitioners continue to dispense their own medicines these misunderstandings are certain to arise, and chemists will claim to prescribe common and simple remedies for what they designate trivial ailments. In many cases, doubtless, the patient may recover, but whether on account of the remedies employed, or because the counter diagnosis was correct, is at least open to doubt. The due recognition of the trivial or serious nature of a malady is not a matter of indifference.

Digitized by Google

The *vis medicatrix naturæ* may often be trusted, and the chemist may be relied upon not to give dangerous doses; but in spite of these two comforting reflections, there is still an element of danger. Faith healing is beneficial occasionally, but it is not to be trusted too implicitly.

THE USURPATION OF HOSPITAL TITLES.

THE French medical press has found it necessary to issue a protest against the usurpation of titles by medical men, a protest which is perhaps not unneeded on this side of the Channel. It seems that a good many practitioners are fond of describing themselves as *ex internes des hôpitaux*, which is about equivalent to styling oneself "formerly house surgeon (or house physician) to a London hospital." In some cases these men have never been *internes* or even *externes*—a class somewhat equivalent to our senior or full dressers or clinical clerks,—and have never had the temerity to compete for these appointments, which are all given after a competitive oral examination styled a *concours*. In other cases they have really been *internes*, but only in the pharmaceutical department of one of the great hospitals, or perhaps in the wards of some workhouse or other infirmary in Paris or in the provinces, where the competition is not very severe, or where, as in some cases, the appointments are obtained by interest. Another way by which practitioners sometimes endeavour to impose on their patients is by describing themselves as hospital physicians, and in order to give colour to the statement these gentlemen tell their patients to address letters to them at such-and-such a hospital, making it "all right," of course, with the porter, and ostentatiously driving up to the door and letting their carriages be *en évidence* in the court-yard. This reminds us of a well-known story of a cheap dispensary practitioner near London who, it was related, after a "chronic" studentship, succeeded in persuading the somewhat lenient examiners of a certain licensing corporation that he was fit to be entrusted with the lives of Her Majesty's subjects, but who nevertheless was firmly believed by many of his patients to have the sole charge of his old hospital every Sunday. It is difficult to suggest any legal means which would put a stop to the assumption of titles by unauthorised persons, and it is probably hopeless to expect.

THE SEAMEN'S CONGRESS AND THEIR GRIEVANCES.

THE first annual Congress of the Amalgamated Sailors' and Firemen's Union of Great Britain and Ireland was held at Cardiff last week, when about sixty delegates, representing some 70,000 seafaring men, drew public attention to important subjects bearing upon the sanitary environment of seamen afloat, specially to the case of firemen and coal trimmers, a class who are practically the backbone in the steam department of our British Mercantile Marine, upon whose physical health, efficiency, and "staying powers" the engineers anxiously rely for maintaining the high rate of speed of our modern steamships. The grievances of this class may be thus briefly summarised:—Defective ventilation of firemen's rooms when situated on a lower deck near the hot machinery; when located on the upper deck the absence of steam apparatus for warmth and dryness; often no arrangement for drying their wet clothes elsewhere than in their rooms, or by hanging them in a position exposed to the eyes of passengers, objected to, and properly so, by the commander; bath-rooms for personal cleanliness are the exception instead of the rule; their duties too often exceed the regulation four-hour watches, the strain of an extra two hours acting injuriously on their health; that the attention of the ship's surgeon being mostly confined to passengers, he is not only discouraged in any inclination to inspect their rooms, but is only sent for there to see a fireman too ill to walk to the surgery; the surgeon, moreover, is often young and inexperienced. These complaints, we are assured, are based upon facts, and we trust that one practical result of the Congress will be improved sanitation aboard, and on the part of the Seamen's Union a supply of healthy, sober, and efficient firemen.

JAMES PRESCOTT JOULE.

FEW greater or more successful workers in science have ever lived than he who died at Sale on Friday, the 11th inst., after many years of infirm health. It is too soon to appraise the full value of his discoveries, but this much is certain, that the name of Joule will take a place in the history of science parallel with, and in honour hardly inferior to, those of Dalton and Darwin. It may almost be said that Joule made physics an exact science. Such a statement would, of course, be paradoxical, for many good workers preceded, accompanied, and followed him. In his greatest work, the determination of the mechanical equivalent of heat, Joule was not wholly original, for that wonderful genius, Meyer of Heilbronn, a provincial physician, had very shortly before, and unknown to the English physicist, worked out the main conclusions on paper from theoretical considerations. But all this detracts nothing from the glory of Joule, who, by the most patient and intelligent labour, did the work and fixed the equivalent, which is now the starting-point in so many studies in physics, chemistry, and biology. In the lustre of Joule's greatest achievement his minor discoveries may possibly be overlooked. Fortunately, the Physical Society of London have recently collected and printed his works, so that their full value may easily be estimated. In some of them he was associated with Sir Lyon Playfair, who has given to statecraft a mind which was meant for science.

THE MEDICO-PSYCHOLOGICAL ASSOCIATION.

AN examination for the certificate in psychological Medicine, given by the Medico-Psychological Association, will be held in December. Candidates intending to present themselves for examination are requested to apply for particulars, and give fourteen days' notice in writing (unless unavoidably prevented), to either the general secretary of the Association, Dr. Fletcher Beach, Darenth Asylum, Dartford; the secretary for Scotland, Dr. Urquhart, Murray's Asylum, Perth; or the secretary for Ireland, Mr. Conolly Norman, Richmond Asylum, Dublin, accordingly as they desire to be examined in London, Edinburgh, or Dublin. The exact date of the examination and further particulars will be announced in due course.

DIPHTHERIA.

DR. T. G. ROBINSON of St. Louis, in a paper on Diphtheria read at the Association of American Physicians, concludes that this disease is acutely infectious, doubtless due to a living organism (microbe), the exact identity of which cannot yet be regarded as settled; that it is primarily local, the system being generally infected secondarily through absorption of poison generated at the primary seat of inoculation; that the contagium may be transferred in a dry state through air for limited distances, in foul clothing, and in polluted food and drink, especially milk. Until the problem of the conditions favourable to the growth and development of the germs is solved, and their life history and habitat are understood, no "definite plan can be formulated for the arrest of the contagium, nor for the hopeful treatment of the disease." He points out that although often not strictly a filth disease, nevertheless

Digitized by Google

certain kinds of filth—as the ordure of animals, and notably the refuse of cowsheds and dairies—afford favourable conditions for the culture of the diphtheritic germ.

HOT-AIR INHALATIONS IN PHTHISIS.

AT the recent meeting of the Association of American Physicians (*Med. News*, Sept. 28th), Dr. Trudean reported the results of the treatment of four cases of pulmonary tuberculosis by Weigert's method. Clinical evidence did not show any appreciable result, and no effect was produced by the method either in diminishing the number of bacilli in the sputa or impairing their virulence, as tested by inoculation.

A "MUTUAL AUTOPSY SOCIETY."

THE death of General Faidherbe, who was one of its members, has brought this curious Society somewhat prominently into the light. Its existence is not a thing very generally known, although its origin is by no means of quite recent date. According to M. Laborde, the vice-president, who has recently been explaining the objects of the Society to the public, it was founded because up to the time of its foundation the opportunities of making post-mortem examinations were almost entirely confined to hospital physicians, and even then they made the examination on subjects about whose previous history, outside their medical one, very little or nothing was known. But, there being an intimate relation between the structure of the brain and its functions, the members of the "Mutual Autopsy Society" hold that very little real scientific progress will be made until it is possible to study the brains of persons previously known either by their deeds or by their works. The members therefore formed themselves into this Society, which addresses itself to everyone having the interests of humanity and science at heart, as well as to those who, having been useful during life, have the laudable ambition to be useful after death. Enrolled as members are several ladies; and amongst the remarkable men whose brains have been examined by the Society are Gambetta and Broca. The third convolution in the great orator's brain was anticipated to be well developed, and, as a matter of fact, it was found post mortem that this convolution so intimately associated with speech was much more developed than is generally the case, even in intelligent men.

DIPHTHERIA AT UXBRIDGE.

WE learn that diphtheria has become persistently prevalent at Uxbridge, and that the local authority and their officers have, as yet, been unable to ascertain the cause of it. By some it is suggested that insuction into the water mains is responsible for the outbreak; but water pollution, whether by an occasional or a permanent cause, cannot often be credited with the spread of diphtheria. Application has been made to the Local Government Board for an inquiry into the subject, and the visit of a medical inspector has been promised.

"COMPULSORY VACCINATION."

IN our issue of last week under the above heading, we commented on statements made at a recent meeting at Guildford. We said that the audience was told that in Sheffield during the last small-pox epidemic, "eight cases, nurses and attendants in a hospital, who had all been revaccinated, occurred, and there were two deaths." We then proceeded to show from Dr. Barry's report that the story as to Sheffield was without foundation. We have now received a letter from Mr. Alfred Milnes, M.A. Lond., F.S.S., stating that this event occurred at Perth, and asking us to withdraw our statement. He encloses a copy of the *Surrey Advertiser and County Times* of Oct. 5th, which contains a report of his address and which shows clearly enough that Mr. Milnes referred to an outbreak in the Perth Infirmary and not to any occurrence in Sheffield. We therefore owe Mr. Milnes an apology, and desire to state that our comments were based upon a report of his address in the *West Surrey Times* of Oct. 5th, which reported him as follows: "In Sheffield, where the percentage of vaccinated persons was 95, between March and December, 1887, there were 2728 cases of small-pox. Eight cases, nurses and attendants in a hospital, who had all been revaccinated, occurred, and there were two deaths." At the present moment we are not in a position to discuss the accuracy of his story in its relation to Perth, but we may do so on a future occasion.

APPOINTMENT OF MEDICAL OFFICER OF HEALTH AT WOOLWICH.

OWING to some oversight in the legislation of the past, Woolwich has hitherto been in the rather curious position of being under no obligation to appoint a medical officer of health. Now at last the local authorities have been compelled to do as their neighbours do, and so they are proposing to appoint a medical officer at a salary of £100 a year, which, as such appointments go, may be regarded as a fair remuneration, considering the limited area of the town and the fact that a large part of it is under the charge of the military authorities, who usually appoint one of their most efficient medical officers to perform the "sanitary duties." The principal practitioners of Woolwich have petitioned the Local Board to appoint some gentleman who is not in practice in the locality, but who is fully acquainted with the conditions under which practice is carried on.

THE NEW ENTRIES.

THE following is a list of the fresh entries for the current winter session (1889–90) at the various medical schools from which returns have been received, together with a column giving the totals for the winter session of 1888–89, for purposes of comparison.

	Entire Course.	Special, Dental, or Preliminary Classes.	Total.	Totals, 1888-89.
St. Bartholomew's	108	37*	145	128
Charing-cross	55	5	60	68
St George's	31	2	33	33
Guy's	91	53	144	103
King's College	37	41	78	111
London	75	40	115	120
St. Mary's	55	8	63	111
Middlesex	43	68	111	102
St. Thomas's	71	41	112	126
University College	61	93	154	153
Westminster	21	13	34	23
Birmingham	37	50	87	†
Newcastle-on-Tyne	42	21	63	68

* Students for the Preliminary Scientific Examination are not counted as students of this hospital. † No return.

TUBERCULOUS MEAT.

THE recent decision at Glasgow respecting tuberculous meat has naturally occasioned increased vigilance on the part of meat inspectors, and has already caused in Sheffield a movement among butchers to attempt the establishment of some definite rules for the condemnation of the flesh of tuberculous beasts. It is contended that when the affected animal is in the early stage of the disease the meat cannot be considered unwholesome, although this contention, however, did not find favour with the experts examined at Glasgow. This view was, indeed, expressed by a deputation of the Sheffield Butchers' Association to the Health Com-

Digitized by Google

mittee on the 10th inst., which requested that the medical officer of health in the examination of carcases of suspicious quality should act in conjunction with a jury of three butchers, and a veterinary surgeon appointed by them. After hearing the deputation the committee adjourned the consideration of the question until its next meeting.

CASEINE.

AN investigation that adds to our knowledge of the nature of a substance of physiological as well as of chemical importance, such as the albuminoid body caseine, cannot fail to be full of interest. Hlasiwetz and Habermann some time back obtained leucine, tyrosine, glutamic acid, aspartic acid, ammonia, and a viscid uncrystallisable liquid by treating caseine with stannous chloride and strong hydrochloric acid. Since then E. Drechsel has turned his attention to the uncrystallisable liquid so obtained.[1] He has found that by treating this liquid with phosphotungstic acid a precipitate is produced. This was washed with dilute sulphuric acid, heated with baryta water, and filtered. The clear filtrate, after removing excess of barium, was then evaporated with hydrochloric acid. In this manner he got the hydrochloride of a strong base, having the formula $C_7H_{14}N_2O_2Cl_2$. This yielded when treated with chloride of platinum long reddish-yellow prisms of the platinochloride $C_7H_{14}N_2O_2PtCl_6+4H_2O$. Platinic chloride gave also with the mother-liquor from the hydrochloride above a platinochloride which, as may be seen from its formula, $C_8H_{16}N_2O_2PtCl_6$, is homologous with the first.

PROFESSOR JOHN MARSHALL.

WE are glad to learn that Professor John Marshall, President of the General Medical Council, has quite recovered from his recent indisposition. It will be remembered that Professor Marshall was prevented by a somewhat severe cold from delivering his introductory address at the sessional opening of the School of Pharmacy, the address being accordingly read on his behalf by Professor Attfield.

INFECTIOUS DISEASES IN SALFORD.

THE want of accommodation for infectious diseases in Salford, together with the existence of overcrowding in the Wilton Hospital, is causing a good deal of feeling in the borough, and the Working Men's Sanitary Association have now taken up the question, and have passed a resolution condemnatory of the present state of affairs. Probably some temporary arrangement will at once be made for the isolation of the excess of diphtheria and scarlatina patients; but we trust that after the present experience no further delay will occur in proceeding to complete adequate permanent accommodation for the borough infectious cases.

FOREIGN UNIVERSITY INTELLIGENCE.

Buda-Pesth.—A special examination was recently held, by direction of the Minister of Education, for the purpose of "Nostrificating" the Edinburgh M.D. held by Dr. John Brodie, who is engaged in attending the workpeople of a company in Nagy-Bánya. As the candidate was not acquainted with the Hungarian language the examination was conducted with the help of a sworn interpreter. The subjects included were Surgery, Medicine, Forensic Medicine, and Hygiene, and the examination seems to have been entirely oral. Dr. Brodie satisfied the examiners, and was granted the *ad eundem* degree of the University, this being the first instance in which such a circumstance has occurred. Usually any foreigner desiring to obtain an Austrian medical degree is required as a preliminary step to become an Austrian subject. It is not stated that this condition was insisted on in the present instance.

Göttingen.—The new surgical clinic in the Ernst-August Hospital has just been opened.

Heidelberg.—Dr. Fritz Bessel-Hagen, whose researches in anthropology are well known, has been raised to the rank of Extraordinary Professor.

Lausanne.—Dr. Bourget of Geneva has been appointed Professor of Materia Medica and Therapeutics.

Liège.—Dr. Fraipont has been entrusted with the theoretical and clinical lectures on Midwifery. A good deal of discussion has recently taken place concerning the medical arrangements connected with the University. Amongst other matters there seems to be a great want of teachers of clinical specialties, and, on the other hand, a redundance of surgical and medical assistants, including several *chefs de clinique*, who are said to be superfluous. Comparisons are freely drawn between this, which is a "State University," and Brussels and Louvain, which are free universities, these latter institutions being, as it would seem, better provided with clinics and clinical teachers.

Munich.—An Extraordinary Professorship of Clinical Medicine and another of Inorganic Chemistry is to be founded, and a Pharmacological Institute established. The last is to cost about £1500.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.

THE deaths of the following eminent foreign medical men are announced:—Dr. Emil Zeising, Assistant Physician in the Dermatological Clinic, Breslau.—Professor Nagous of Lyons, who was, together with a Sister of Mercy, stabbed by a patient upon whom he was about to operate, and who, not being as fully under the influence of chloroform as was supposed, was so enraged at the touch of the knife that he snatched the instrument, and before he could be stopped had plunged it into the hearts of the unfortunate professor and the sister in attendance. The Courts will have to decide how far the man was morally responsible.

THE Library of the Royal College of Surgeons of England will be kept open until 9 P.M. for the remainder of the year. There has been a wish expressed by various members of the profession that the Library might be available for a longer time during the day, and the Council agreed at the quarterly meeting held on Thursday, the 17th inst., to keep it open from 11 A.M. to 9 P.M. Should sufficient readers avail themselves of the advantages thus offered, the hours will probably remain as thus changed.

CESENA, in the Romagna, not far from the Adriatic seaboard, is now a health resort, in which the resources of the place for mineral baths and for the "climatic cure" are intelligently and carefully utilised in a well-appointed establishment. Year by year Italy is availing herself of her natural advantages for such institutions, in pursuance of the movement initiated *ad hoc* at Bologna, and continued at the thirteenth congress, which lately concluded its sittings at Padua.

THE next meeting of the Royal Medical and Chirurgical Society will, as announced in our advertisement columns, be held on Tuesday, the 22nd inst., at the Society's new house, 20, Hanover-square, in a portion of the library temporarily adapted for the purpose.

OF the 557 members returned at the recent general elections to serve in the French Chamber of Deputies, 48 are doctors of medicine, 4 are druggists, 1 is a dentist, and 1 a veterinarian.

Pharmacology and Therapeutics.

TOXIC EFFECT OF CREOLIN VAPOUR.

A CASE of poisoning by creolin vapour is reported by Dr. Stille-Ihlienworth in the *Memorabilien* of July. The author had to procure premature delivery in a case of contracted pelvis, and used as a disinfectant for his hands and instruments an emulsion containing 1½ per cent. of creolin, which from the afternoon until the next morning stood in two open saucers in the next room. In the evening he complained of pain in the right temple and occiput, and his pulse rose from 70 to 100. When he moved about the latter even rose to 120, and the carotids pulsated very perceptibly. These symptoms only ceased a few hours after he had gone into the fresh air. All the other people who had been present in the room became similarly affected, and one suffered more severely, vomiting supervening on the other symptoms. Returning the next afternoon to the patient's house, the writer felt quite well. He again prepared two saucers of creolin, dipped his hands into the solution, examined his patient, removed the catheter, which in the morning had been inserted between the wall of the uterus and the membranes, washed his hands, and carefully disinfected the catheter. The same symptoms reappearing, he entertained no doubt that the creolin vapour was the cause of the seizure. The saucers with the disinfectant were then removed, and only brought back when they were actually wanted, and no further abnormal symptoms appeared.

CHRYSAROBIN IN HÆMORRHOIDS.

Dr. Kosobudski, writing in the *Russkaya Meditsina* on Unna's plan of treating hæmorrhoids with chrysarobin, says that he has employed it—or a modification of it—in twenty-two cases, and has found it on the whole very satisfactory. He does not, however, employ quite such strong preparations as Unna. His plan is to wash the hæmorrhoid with a weak carbolic or creolin lotion and then to dry it well with cotton wool, after which he applies three or four times a day an ointment consisting of chrysarobin 8 parts, iodoform 3 parts, extract of belladonna 6 parts, and vaseline 150 parts. For internal piles suppositories are employed, which are composed as follows: Chrysarobin, 1 gr.; iodoform, ¼ gr.; extract of belladonna, ½ gr.; cacao butter, 30 gr.; glycerine sufficient to enable the mass to be made into the form of a suppository. If there is much hæmorrhage a tannin suppository must be used. After three or four days of this treatment the pain and hæmorrhage disappear, and after three months or so the hæmorrhoids are found to have almost completely shrivelled up.

HYDRASTIS IN MEMBRANOUS DYSMENORRHŒA.

Dr. Franz Jordán relates in a Hungarian medical journal an interesting case of most obstinate membranous dysmenorrhœa in which after many years had been spent in trying all manner of different methods of treatment hydrastis canadensis rapidly effected a cure. Dr. Jordán employed the liquid extract of hydrastis canadensis, twenty-five drops of which he ordered twice a day. This very soon began to produce an appreciable effect, and after a short time the medicine was required only at the time of menstruation or for a few days previously, the loss of blood becoming very slight, and the pain disappearing altogether.

IS PHENACETIN A REMEDY IN WHOOPING-COUGH?

Dr. R. Heimann of Laudau answers the above question affirmatively, having used the drug experimentally in a case in which antipyrin entirely failed. The success was so surprising that he administered the drug in two other cases. It reduced the number of paroxysms, which had been from ten to fifteen per diem, to three, and on some days they entirely ceased, only reappearing at night, when no phenacetin was given. Dr. Heimann gave a boy of three years six grains in four doses of one grain and a half, a girl of two years five grains in three doses, and an infant of seven months three grains in four doses, without observing the slightest ill effects. One grain and a half of phenacetin would, on the average, retain its effect for three hours. The author recommends further trials of the drug.

IODIDE OF POTASSIUM A CARDIAC TONIC.

M. G. Sée has recently pointed out, before the Academy of Medicine, that iodide of potassium, far from being a depressant, is really a cardiac tonic, of almost equal value to digitalis or strophanthus in certain cases. Indeed, he says that iodide of potassium is the real cardiac drug (*vrai médicament du cœur*), since, when prescribed in cases of uncompensated mitral lesions or affections of the myocardium, it increases the cardiac power and raises vascular tension. Thus, by subsequently causing dilatation of the arterioles, it enables the heart to recover its power and affords also better facilities for the coronary circulation, thus improving the nutrition of the heart muscle.

DRY-AIR FROZEN FRESH FISH.

BY J. LAWRENCE-HAMILTON, M.R.C.S.

No. IV.

To obtain an imperishable, cheap, healthy, abundant supply of fish food, it is necessary to bleed, gut, and clean the fish at once on capture, and then forthwith transfer the fish so treated to the dry cold air refrigerator chambers of special steamers at the fishing grounds. Much of this hard frozen fresh fish should be distributed to the fish markets, wharves, and stores situated on canals and rivers by dry-air refrigerator barges or insulated covered barges for shorter distances, whilst seaport towns could receive the fish direct from the refrigerator steamers, as well as towns like London having wide and deep rivers. As far as possible all railways should be avoided. In the United Kingdom their extortionate rates for the carriage of fish have for long oppressed the fish trades to the special injury of the poor. However, if frozen fish has to be sent long distances by rail to towns unprovided with canals, rivers, or lakes, as in some of the American cities, then special refrigerator railway fish cars are advisable.

The treatment of fish on capture.—To preserve fresh fish, free it from moisture and bacteria. Kill as quickly as possible. Where practicable, all fish immediately on capture, prior to the coagulation of the blood, should be gashed under the head just behind the gills, the usual situation of the heart in most fishes, or else above the tail, which has been the practice from time immemorial in Scandinavia and in Holland. Compared with land animals, fish have but very little blood to lose, and hence fish on being bled become at once faint, which rapidly passes into insensibility. Next speedily gut the fish so as to remove its entrails, including the liver and roe. In big valuable fish like the salmon it should also be pithed, by exposing and removing with a gutting knife the comparatively diminutive brain (a characteristic of all fishes), and then push a copper wire into its spinal canal so as to break up the substance of the spinal marrow. Removing its brain abolishes sensation and volition, whilst destroying the spinal marrow arrests all muscular movements. Finally, thoroughly clean each fish inside and outside with abundant washing in clean, fresh-flowing water, sea water being for every class of fish better than spring water. Though gutted fish keep better and longer by the addition of salt or brine into the cavity of the body, I recommend peat moss as being cheaper and much more effective. As peat moss is universally abundant in Ireland, its fishermen should use it freely.

Norwegian fishermen roughly estimate that by bleeding, gilling, and gutting flat fish about one-sixth of the total weight is lost, whilst long fish by bleeding and gutting forfeit about one-fourth of their total weight. In spawning fish, being full of roe, these proportions would be materially increased. A codfish weighing 21 lb. is said to have furnished 12 lb. of roe. Thus, especially for railway borne fish, this economy in freight would mean a great saving to the public—the fish consumers. Later I shall show the avoidable colossal commercial losses incurrred in the United Kingdom by its neglecting to judiciously work up the by-products or waste products of fish and fish refuse, which in the United States of America amounts to upwards of 14 per cent. of the total value of their fisheries.

Use of carrier pigeons and telegrams for sea fisheries.—Fishing fleets should signal by means of carrier pigeons for the refrigerator steamers to come out from the harbours to remove the catch. These carrier pigeons would be useful to the smacks in case of accident and distress, and could also

Digitized by Google

be employed by the fishermen to send messages, weighing up to two ounces, to the steamers, also to bring out any articles required by the fishermen, including food, medicines, fishing-nets, tackle, bait, and other requisites. Alighting on the platform of the pigeon house, connected with an electric bell for day and a light for night work, the pigeon announces its own arrival. Fishermen and sailors would soon learn to train and breed these carrier pigeons at a trifling cost. After a while, probably, no fishing smack would put to sea without a few carrier pigeons. The Admiralty should keep ready for use a large number of carrier pigeons, as in case of war along our coasts and colonies, these local marine messengers would be invaluable, especially to ships of war and torpedo vessels defending our coasts, mouths of rivers, and harbours.

Night and day, along the chief Norwegian fishing fiords and grounds, special local telegrams inform the fishing fleets as to the location, the probable destination, and expected time of arrival of observed shoals of fish. Doubtless much might be done on our own coasts by combining and collecting information for telegraphic purposes brought by these carrier pigeons as to the probable course of various migratory shoals of fish. Like the Chinese, the Norwegians, through centuries of acquired observation, are shrewd, trained experts in noticing the habits of fish. Lately, whilst visiting the Norwegian fishing towns from Christiania to the North Cape and back, I was informed that the Norwegian Government gratuitously circulated these trade messages for the benefit and advantage of their fishermen. The Government of the United Kingdom should initiate and imitate similar plans on behalf of our chronically neglected fishermen, as, setting aside the just claims of our brave fishermen for such trade information, this would also cheapen fish, and therefore relieve some of the burdens of the taxpayers.

Dry-air refrigerator steamers.—For carrying the fish from the fishing fleets at the fishing grounds, specially constructed coal-saving refrigerator, swift steel steamers, of about 200 to 300 tons each, would be advisable. The present frozen meat ships have chambers insulated with thick layers of charcoal, though peat moss would be more economical and efficient, whilst in case of repairs from accidents peat moss is much cleaner and weighs less than charcoal. In storing hard frozen fish as far as practicable leave an air space around each big fish, whilst large valuable fish, like meat carcases, are best kept clean and undamaged by a separate canvas shirt or sack. Small fish can be packed in layers of peat moss. Men engaged in handling frozen meat use thick woollen gloves and felt shoes, with canvas suits over their clothes, whilst the engineer's assistant, who has to remove the accumulating snow from the refrigerator chambers about every four hours, is on these occasions dressed in a specially warm thick suit of woollen clothes. In the frozen meat trade for rivers and canals, covered barges insulated with felt (though peat moss would be better) are employed; whilst for longer distances specially constructed insulated covered refrigerator barges are so made that from the frozen meat ships, or else from the refrigerator wharves on shore, cold air can be pumped into them. However, the present refrigerator and insulated barges both admit and invite many economical improvements.

Dry-air frozen fresh fish is imperishable.—In Russian winters fish is naturally frozen for months, and is sawn for the retail customer. Fish is kept frozen naturally by the dry, cold, winter air in the Hudson Bay territories, in the elevated regions of Thibet, and in arctic winter climates generally. The frozen meat ships for a forty-five days passage from London to New Zealand keep fish frozen for their passengers' food, though usually omitting to have such fish previously bled and gutted. For years the Hudson Bay Company shipped frozen salmon (though *unbled* and *ungutted*) to London, Australia, New Zealand, &c., but now the Canadians find that it pays them better to deal with the United States. Salmon brought from Labrador in the s.s. *Diana* kept good frozen for 200 days, whilst in the Canadian Court of the 1883 London Fisheries Exhibition frozen salmon after eighteen months of such treatment was found to be excellent eating. A frozen fish trade is now carried on between Senegambia, in West Africa, and Marseilles. By means of a mixture of ice and salt a large remunerative hard frozen fresh fish trade has long been successfully carried on in the American United States, where refrigerator steamers fetch fresh fish from the fishing grounds, freeze it hard, store it as long as required in specially constructed insulated refrigerator wharves and warehouses, and when necessary deliver it frozen, in specially constructed fish refrigerator railway cars to inland distant districts unprovided with canals, rivers, or lakes. However, this salt and ice process is much dearer than the dry cold air methods.

Refrigerator insulated wharves and stores.—It is only quite recently that the dry air machinery for ships, wharves, warehouses, and railway cars has been sufficiently perfected to work well, cheaply, and regularly, so as to be commercially remunerative. Hence the first losses of the earlier introducers of the frozen-food trades are now avoidable. It is to be expected that in the near future further improvements in the economy and efficiency of the frozen-food trades will be introduced, though already, at home and abroad, several rival plans and patents compete for business. Setting aside minor details, the best processes for food freezing may be thus briefly summarised. The average temperature of the cold air in the special ships and storehouses is turned on at 70° to 80° below the zero of Fahrenheit, or upwards of 100° F. of frost. For meat the cold in these refrigerator chambers can be accurately regulated by the machinery, which usually keeps the chamber at 16° to 22° F., though in the case of fish a less amount of cold is necessary. For this purpose the air to be cooled is so greatly compressed that its temperature becomes elevated to about 240° F. This heated air then passes through a long series of pipes surrounded by cold water, which absorbs the heat of the compressed air, bringing this air down to the temperature of the cool water. This air is next let into another vessel surrounded with cold air where it deposits all its moisture, for it is essential that the air for freezing food should be freed from every trace of water or moisture. By this time the doctored and dried air has become cooled to about 70° F., when it is suddenly and rapidly expanded, and thereby becomes so intensely cold, that the air passes out of the machine at a temperature between 70° and 80° below zero, Fahrenheit, or upwards of 100 degrees of frost. This dry cold air circulates through the refrigerator chambers and afterwards returns to the compressor machinery, to be again further dried and cooled down to 70° or 80° below zero. The refrigerator chambers have walls, floors, and ceilings composed of severals layers of non-conducting or insulating materials, general charcoal, with specially constructed massive insulated doors, so as to hermetically seal the refrigerator compartments. Here the substitution of peat moss for charcoal would be an economy.

Some frozen meat removed from the refrigerator ship *Tainui* to a covered insulated barge maintained three degrees of frost after fifty-five hours, although after the first twenty-four hours had elapsed about half the frozen carcases in their canvas shirts were withdrawn. These stores are kept scrupulously clean, and usually lit up with electric light, so as to avoid injuring the food. Each carcase in its shirt is hung up separately. During 1888 London and Liverpool alone imported 1,924,000 carcases of frozen meat, which was an increase of upwards of 300 per cent. of the amount imported five years previously, or in 1884.

Quantities of imported frozen meat are often retailed by butchers and at restaurants at the high prices of freshly killed prime English meat, and paid for by the consumer as if for English meat, as he, like the skilled analytical chemist and microscopist, is unable to taste or to detect any difference in freshness or flavour between frozen and freshly killed meat. This fraudulent trading should be stopped by a special Act of Parliament, which should also forbid foreign cattle being sold as British beasts.

	Percentage of Foreign Imports.

Cattle (including calves, but excluding milch cows) ..	36	40	51
Sheep and lambs	51	54	55
Pigs	94	98	97

Cheap, healthy, frozen, fresh fish for the poor.—Freshly caught herrings and sprats, as well as occasionally mackerel and other fish in colossal quantities, at the fishing grounds can both at home and abroad be purchased wholesale at mere nominal prices, as such fish so rapidly decompose or putrefy that frequently coasting vessels, especially on Saturdays, either throw them back into the sea or else dispose of them for manure. Because of the now past impossibility to deliver cheap and coarse fish in a fresh,

Digitized by Google

eatable condition, and the prohibitive prices usuriously placed upon such fish by rings of non-fishermen fish auctioneers, fresh fish has not been largely or properly supplied to the poor of the United Kingdom. The dry air frozen fish trades can alone remuneratively supply fresh fish at a low price to command an extensive sale among the poor and the comparatively poor, who should thus in London be able to buy healthy gutted and bled fresh herrings with their roes at ½d. per lb. The average weight of an ungutted herring may be taken at about 7 oz., so about three gutted herrings would hardly weigh 1 lb. avoirdupois. The abnormally high nutritive food value, the light, easy, rapid digestibility and solubility, with its excellent and varied flavours of the flesh, the hard and soft roes, should recommend the frozen fresh herring as the poor man's special healthy food. It is often called a "two-eyed steak," or a "Billingsgate pheasant," and in other parts of the United Kingdom the red herring is variously known in popular language as a "Glasgow magistrate," a "Gourock ham," or a "Norfolk capon." The general introduction of the herring into the daily dietary of workhouses, poorhouses, asylums, prisons and the like, should effect considerable reductions in the general poor rates of town and country districts. Sprats are also excellent cheap food for the poor, and, like the herring, are palatable fresh or cured.

New kinds of food fishes.—The gradual introduction of several home and foreign fish, which, though cheap and nutritious, have by changing capricious custom hitherto been neglected or else gone out of fashion. Hence on capture by our fishermen, being unsaleable in the local markets, such fish are often thrown back into the sea, is a subject which induced some Americans in New York to found an Ichthyophagus, or fish-eaters, Club, with the sole object of introducing hitherto unrecognised fish food. A similar institution would do much good in London.

The distribution of cheap, frozen, fresh fish.—The system of bled, gutted, cleaned, dry air frozen, imperishable fresh fish properly conducted would, in a great measure, do away with the preponderating influence of the middleman, the non-fisherman fish auctioneer, whose market rings or combinations have hitherto kept fish not alone at usurious prices, but have also supplied fish always more or less deteriorated in quality, often uneatable, sometimes unfit for human food, and occasionally even poisonous. By the unavoidable introduction of frozen fish, both the fishermen and the fish vendors themselves will be great gainers, as, with an extended commerce, they will cease to deal in a perishable product, and also no longer require to waste their money on ice. In time, every large town or district will require its own refrigerator stores or depôts, where both frozen fish and meat could be preserved to supply the local traders, who would thus never have to suffer from the pecuniary loss of over-stocking themselves with perishable food. I estimate that, including all freights, costs, and charges, the wholesale selling price of fresh fish in the markets of the United Kingdom now (1889) already exceeds £15,500,000 a year. But by judiciously pushing and developing the dry air frozen fresh fish trades this wholesale commerce for home and export consumption could in a few years be made to exceed £100,000,000 a year. It would be a national disaster if foreign competition were to secure such a trade, which, in addition to its financial aspect, includes the best school in which to train sailors for our navy, a fact long recognised by the Dutch and French.

In 1636 Charles I. accepted upwards of £30,000 to allow the Dutch to finish their year's summer fishing for herrings off the coasts of England. This illustrates the value, even in those days, of the herring fisheries. Returning, however, to fish purveyors and distributors, it must be recollected that the retail markets and the fishmongers combined cannot compete in quantity with the small fish costermonger or perambulating fishmonger, who is the most useful and extensive fish vendor. To the fish costermonger the system of frozen fish would be as great a boon and a blessing as it would be to the poor and to the comparatively poor. These costermongers are generally but small capitalists, and indeed not unfrequently borrowers, requiring to sell their first load before they can afford to purchase a second lot. Hence, as soon as they had sold one cargo, they could with these returns and profits purchase a further supply from the refrigerator stores, and thus, doing an extensive increased business, they would be able to earn more money whilst selling better and cheaper fish to the poor. By a police law of the City no fish carts or barrows may remain near Billingsgate after 9 in the morning; so, should a costermonger require to replenish his stock, even at 11 in the morning, this anomalous market has practically ceased to exist for that day. It is useless for the poor to make hard sacrifices by long strikes so as to get higher wages unless they can also obtain better, cheaper, healthier and more abundant food. Hitherto the chief increase of their wages has been virtually almost useless, because it has not been combined with suitable food at lower prices and better value, an all-important fact which is too often entirely overlooked and ignored. Therefore these strikes practically chiefly benefit the middleman.

Frozen fish at unvarying prices.—The poor are naturally puzzled, perplexed, and frightened at the present ever-varying and fluctuating prices of the same kind of fish under the existing wasteful fish-destroying systems, and is another reason why they will welcome the advent of frozen fish. The total supply of frozen fish will be quite independent of local fogs, storms, calms, and the catch of the preceding twenty-four hours. Frozen fish should therefore remain all through the year at constant prices.

Cheap cooked fish for the poor.—Not alone do the poor require close at hand cheap fresh fish, but as many of them have often to work miles away from their homes, it is to be hoped that the introduction of frozen fish will result in numerous local retailers selling healthy cheap cooked fried fish. It is evident that it is no practical economy for a workman himself, distant from his home, to be able to buy cheap fish if its cooking costs him not alone too much for fuel, but further involves his sacrificing an hour's work or more to make up a fire to cook a single herring for his meal. At present it is a notorious fact that much of the fried fish sold to the poor is fish which is more or less bad and decomposed, and would be unsaleable in the uncooked state. Hence the true commercial saying among some of these fried fish vendors, that "*Frying a fish saves its life.*" It is evident that such fish is likely to produce passing disease among those whom stern necessity, hunger, and poverty compel to eat food which, under a proper system of inspection, could not be sold.

The signs of bad fish.—Among the indications of decomposed fish are external and internal bleeding and clotting, which clotting is intensified by cooking, and is so frequently seen extending along the backbone of cooked fish. Cloudy, opaque, sunken eyes; dry looking gills; flabby, soft, insipid flesh; a fishy smell; loss of brightness and brilliancy about the scales; any luminosity or phosphorescence in the dark. When cooked a sour or acid taste, with darkened clotted blood, indicate decomposed fish. The blackening of a silver spoon indicates sulphur, a product of fish decomposition. In Italy cured fish is tested by introducing a skewer whose subsequent odour indicates the condition of the fish.

THE PARIS UNIVERSAL EXHIBITION.

(FROM OUR SPECIAL CORRESPONDENT.)

The International Congress on Climatology and Hydrology.—The Perfumery Section.

THE International Climatological and Hydrological Congress has just held its sittings at the École de Médecine. This is the second congress of the series, the first being held at Biarritz in October, 1886. Unfortunately the present season is not so favourable. Medical men are thoroughly exhausted by the great number of congresses that have met during the Exhibition, and these have all suffered from mutual competition. Nevertheless fourteen different Governments have sent official representatives to the congress, notably the Belgian, Dutch, Italian, Spanish, Austro-Hungarian, Mexican, and Turkish Governments. There are also unofficial delegates from England, the United States, Switzerland, and other countries. The opening sitting was held at the Trocadero, and the subsequent meetings at the École de Médecine. M. Renou, director of the Observatory of Saint Maur and vice-president of the French Meteorological Society, was elected president, and Dr. Winternitz, of Vienna, delegated by the Austro-Hungarian Government, was elected as foreign president of the congress. In his opening observations the French President said that where good springs existed the climatic and general conditions

Digitized by Google

were sometimes unfavourable, therefore it was absolutely necessary to study both questions simultaneously. Unfortunately meteorology and climatology were sciences much behind date. Also there were any number of amateur meteorologists who, by their incorrect observations, caused more confusion than need be. If these amateurs would first consult the meteorological institutions, and would consent to receive instruction and have the accuracy of their instruments tested, much more satisfactory results would be secured.

The afternoon sitting on the second day was opened by the delegate from the town of Pau, who urged the importance of a uniform system of meteorological observations. He complained that the climate of Pau had been misrepresented by Dr. Weber of the London German Hospital, who had quoted Dr. Williams's animadversions against Pau. There are variations of temperature from year to year, and it was necessary to study the average temperature, not of the whole year, but of the months when such towns were frequented by patients. For instance, at Pau it was necessary not merely to indicate the direction of the prevailing winds, but to add the local circumstance that it was precisely to the windward of the town that the pine-wood forests were situated. It was further very necessary to find out what were the "medical hours" of the day. It was not the climate of a station, the average climate that the patient experienced, but the climate of those special and favourable hours that are known as the medical day.

Dr. Danaciano Moralès, professor at the University of Mexico, and delegate of the Mexican Government, gave some description of the various health resorts of Mexico. These in time would, he said, deservedly be as well known and as popular as the similar stations in Europe. At some of these stations there was already excellent hotel accommodation. Being so near to the tropics, and yet enjoying a mild climate in consequence of their elevated positions, these stations offered exceptional conditions and possessed mineral springs of great value. When, however, the speaker entered into an analytic description of these waters, their virtue was challenged by several members of the Congress. M. Labut said that great abuse had been made of iron waters. Those that were serviceable for medical purposes were very rare indeed. In some cases, notably in the neighbourhood of Milan, the chalybeate waters were so strong that they had to be given a teaspoonful at a time, and this mixed with a large quantity of ordinary water. Water containing iron could be found in all directions, but the iron was precipitated by contact with the air, or other chemicals in the water neutralised its therapeutic utility. Thus, in all France no good iron waters could be found. Those of Orezza in Corsica were really suitable for medical purposes, but the accommodation was so bad that patients could not be sent there. Close over the frontier there were some excellent chalybeate springs—those of Spa in Belgium. But even these had been exaggerated. There were also good iron springs in Germany, though they did not equal the waters of Spa. It was, therefore, necessary to be very careful in this respect. A mere analysis did not suffice; waters might contain a great quantity of iron, but not in such a condition as to render its assimilation possible.

After M. Marcailhon had made some remarks on the waters of the Fontaine aux Fromages at Ariège, M. Mendes Guerreiro, civil engineer, and delegate from Portugal, insisted that it was not only the climate that should be studied but also the soil. The climate, if estimated only by meteorological observations, might be excellent and yet the mortality be very high. The soil, under the best of climates, might be the cause of decimating diseases. Thus the piercing of the Panama Canal seems likely to prove a failure because proper precautions had not been taken with regard to the soil. The workers could not live in such a place. The speaker had been sent to build a reformatory in Portugal on a site where the soil was so bad that fever spread among the workmen. The difference of temperature between the day and night was equal to 30°. The dryness in summer was such that the lips cracked and bled and the trees died; yet in the lower part of the district there were marshes, and these spread malarial fever. His first precaution was to prevent the workmen going out of doors in the evening. Then he planted 100,000 eucalyptus trees, which at first had to be watered artificially. In a few years the temperature so changed that the difference between night and day was altered from 30° to only 18°. M. Guerreiro then discussed various methods for observing temperature, and thought the temperature of the soil very interesting. In Portugal he had found that at a depth in the earth of 2·40 metres there were but two degrees centigrade difference between winter and summer. M. Renou replied that at the St. Maur observatory they could discover no difference between night and day temperature if they went lower than one metre. At one metre from the surface of the soil they took daily observations. The maximum of heat at that depot occurred at ten in the evening, and the minimum of heat at ten in the morning. Consequently it was at those hours that the observations were made.

M. E. Renou, director of the St. Maur Meteorological Congress, presented three papers simultaneously. In the first he argued that thermometers were altered by being plunged into boiling water, and also insisted that thermometers were not exact at every point of the scale of degrees. Therefore it was necessary to submit thermometers to very severe checks. In his second paper he complained that observations were made under circumstances that rendered them worthless. Thus, a thermometer outside a window, warmed by the radiations from a house wall, would only fall to 5° C. while it was freezing in the open. It is best under such circumstances to suspend the thermometer in mid-air by means of a silk thread. In the third paper, dealing with weather forecast, the author regarded the barometer as the best, though not an infallible guide, and urged the utility of health stations receiving regularly the reports of the Meteorological Office. Dr. Fines pointed out that for climate stations what was wanted was a record of the temperature taken during the time when most patients went out for exercise; and M. Japa Wada, the Japanese delegate, spoke at length on cyclones and volcanoes, and their effect on the temperature of hot springs. The water he found was generally warmer before a cyclone, though it gave off less steam. Mr. G. J. Symonds said he had heard, with pleasure, that M. Renou had drawn public notice to the real quantity of rain water, and more especially of snow, that fell, for these were questions which had not yet received sufficient attention. As for the real temperature of springs, Mr. Symonds described the journey he had made in the Pyrenees on behalf of the English Royal Society, so as to verify the temperature of the hot springs in that country. He explained the precautions he had taken so as to ascertain the true temperature, even to the twentieth part of a degree centigrade. To the medical men who had assisted him and rendered him valuable service at the various stations he desired to offer his heartiest thanks, and this in the most public manner possible. With their aid he had been able to ascertain how very slight was the alteration of temperature of the springs during the course of the last fifty years.

Dr. Constantin Paul read a paper on Thermal Therapeutics in the Treatment of Cardiac Diseases. Sudden deaths occurring from the imprudent use of baths have led many medical men to warn their patients suffering from heart disease against hydropathic establishments. Nevertheless, symptomatic palpitations connected with chlorosis, anæmia, affections of the stomach, the liver, and even of the lungs are benefited at such establishments. Still more ought this to be the case in nervous palpitations. When, as a consequence of rheumatism, the auriculo-ventricular valves are affected, the waters of Dax have rendered considerable service, as also those of Aix, St. Nectaire, Mont Dore, and Néris. When the aorta or the myocardium is affected then thermal stations are most dangerous. If there is hypertrophy of the heart as the result of catarrhal disease, then relief can be obtained by the waters that reduce or cure the cause of the disease; the waters, for instance, of Eaux-Bonnes, Cauterets, Allevard, St. Honoré, Pierrefonds, and Enghien. Symptomatic hypertrophy, due to gastric affections, may be sent to Ems, Carlsbad, Vichy, Royat, Vittel, and Contrexéville.

Dr. Bouloumié read a very lengthy paper on the treatment of Renal Disease, concluding that it was necessary to study more carefully the value of the hydro-mineral treatment of albumen in urine; the morbid relations between the liver and the kidneys under the influence of mineral waters; the absolute and relative value of different mineral waters in the treatment of renal lithiasis, and particularly in the treatment of gravel in the urine. Dr. Caulet read a paper on Severe Neuralgic, Ovarian, and Uterine Diseases, which he insisted would be specially benefited by the hydro-mineral treatment. Dr. Grimaud followed with a paper on Hydro-mineral Treatment of Tuberculosis of the Bones, and Dr.

Digitized by Google

Jules Simon on Sea-bathing for Children. The latter speaker also reviewed at length the various mineral waters, and described the nature of the diseases among children which would be affected by use of these waters.

Dr. Labat, member of the Hydrological Society of Paris, who has visited almost every winter and thermal station of England and Europe, spoke several times during the Congress. He also read a very interesting paper on the classification of these stations. In accomplishing this very difficult task he displayed great impartiality and moderation. There were, he thought, three great categories of climate—the plain, the mountain, and the sea; and these, according to whether they were hot or cold, became summer or winter stations. The mountain stations were quite new in the history of the climatic treatment of disease; but he thought the effect produced was generally due to the change of temperature, and not to the rarefaction of the air. It had been shown that the temperature fell 1° C. for every 165 metres of elevation. The Engadine, St. Moritz, La Maloja, were situated at an altitude of about 1800 metres; Tarasp, Bormio, San Martino, were below 1400 metres; Davos, 1550 metres; the Kaltbad of the Righi, 1440; Panticosa, in Spain, 1600 metres; and Barèges, in France, 1250. At these smaller altitudes the slight reduction in the quantity of oxygen is compensated for by the greater density of the air produced by the cold and by the greater activity of the respiratory movements. Jourdanet's theory on "respiratory diet" can only be applied at such stations as Quito, 3000 metres; or Mexico, 2300 metres, and at Dittinghur, 4700 metres; Darjeeling, 2440 metres, or in Switzerland, at the Hôtel de Viesch, 2500 metres. Because the natives of these elevated regions do not suffer from phthisis, therefore, people had jumped to the conclusion that the climate would cure this dread disease. This, however, did not follow. He had found that these mountain stations were generally situated in a high valley at the foot of a big mountain that sheltered them from the north and left them fully exposed to the sun. The topographical position, in fact, was similar to that of a Riviera winter resort. When the weather was fine and the sun shone there was no harm in taking out-door exercise. To this the German doctors have added cold frictions and "pulmonary gymnastics." Satisfactory results had been obtained. But, after all, what was injurious was not the cold of winter; it was the damp, the wind, and the want of sunshine. It was in this respect that mountain resorts were useful. But great precautions should be taken. Disasters had occurred, and some persons, who thought themselves nearly well, went to the mountain stations to complete their cure; and there, on the contrary, the disease met its fatal termination. With regard to the maritime climates, there was a terrible warfare between the South-west, Pau, Biarritz, &c., and the Riviera, Nice, Cannes, &c. The former had greater stability of temperature, and there was not the terrible mistral wind; but then they had violent south-westerly gales, a damp atmosphere, and a cloudy sky. Dr. Labat was ready to admit that there was much to be said on both sides; but the Riviera in any case had the advantage of a brighter sky, a more beautiful sea, and these could not but have a great mental effect on the patient. The real secret was the selection of the site for the building of the sanatorium. On the Riviera there were climates as bad as the worst that could be found in Europe; but at Carabancelle, at Beaulieu, and at Monte Carlo the shelter was perfect and the climate admirable. There was a warm temperature on the south coast of England, and the west coasts of Scotland, but when the sky is not clear the spirit is depressed by sadness, and this places the patient in a bad condition for recovery. If the sun shines, even though the thermometer does not record a better climate, its generous rays warm the heart and the soul, keep up the activity of the skin, inspire hope, cheerfulness, and predispose the patient favourably.

Dr. Cosse of Ostend, in replying, sought to defend the sea coast climate. The winds were for the most part westerly, warm, and richly charged with ozone, and this killed the microbes. The minimum of ozone at Ostend was greater than the maximum of ozone at Brussels. Also the rain that fell at Ostend was at least a third less than that which fell a little way inland. They had much more sunshine than was generally believed. He did not attribute much importance to the salt supposed to be in the air, for he found that at a very short distance from the sea there was no salt, nor did the rain water take up any chloride of sodium from the atmosphere. It was the bath of air rather than the water which benefited the patient.

Dr. de Valcourt supported the bath and spoke of the treatment of strumous children at Cannes by sea-baths during the winter months, entering into minute details of various cases to show the good results achieved. M. Dolfus of Mulhouse had erected a sanatorium at Cannes for 120 children of the working classes. Some came from Geneva, and they began treatment in 1881. They selected a site on porphyry so that there should be no dust, and at first stopped the bathing on Nov. 15th, now they continued till Dec. 20th. After that date the bath is not compulsory, and they ask for volunteers, but nearly all the children volunteer. It is only during exceptionally bad weather that they do not bathe, so that the children during the depth of winter get something like twenty sea baths per month.

Dr. F. Chiaïs of Mentone made some able remarks concerning the increased radiation of heat resulting from dryness of atmosphere. What was wet for the skin caused the lung to experience greater dryness. When there was more than the normal dryness, then accidents arising from cold increased among those who suffered from diseases of the chest and wintered on the Riviera. The hydrometer was really more useful than the thermometer. While the latter would record the same temperature, the former would show that there was a great change in the character of the air. In January and February especially there were very dangerous perturbations, and during periods of excessive dryness patients had better remain at home. Dr. de Valcourt agreed as to the danger of the very dry air, and urged that it did not suffice to tell patients at such periods to boil water in their rooms. They very often would neglect to do so, but if told to put a few eucalyptus leaves in the water they would have more faith in the beneficent effects of the steam. The discussion continued for a considerable time, when it was urged that the most varied medicaments and climates rendered service, and instead of complaining of their number we ought to learn how better to use them.

On the Sunday the Congress enjoyed a pleasant excursion to Pierrefonds, where there are some sulphurous springs and a small hydropathic establishment. Here the Congress was entertained to lunch, the Mayor of Pierrefonds presiding. Time was allowed to visit the magnificent Castle of Pierrefonds, recently restored by M. Violet le Duc, and also the Château de Compiègne, where, under the Second Empire, hunts used to be organised with so much *éclat*.

The next day the Congress, refreshed by this rest, met in full force, and the discussion was opened by the reading of an important report prepared by Dr. Schlemmer on the Influence of Microbes on Thermal Therapeutics. The first question raised was whether the micro-organisms observed in mineral waters might become the cause of danger. In this respect it must be borne in mind that unless the waters are well protected they may receive microbes from the air or the soil in the immediate neighbourhood of the spring, microbes foreign to the water itself. Taking the waters of the Mont Dore in a sterilised pipette, plunged at considerable depth, he had not found that specimens thus collected gave rise to any cultures. So far he had not discovered that microbes in mineral waters had produced any special effects, whether these were added to the waters or were inherent to the waters, such as the Leptothrix ochracea of chalybeate springs, to which M. Winogradsky attributed an action in reducing sesquioxide of iron. All that science had at present demonstrated as necessary was the careful shielding of mineral springs from external contaminations. Dr. Schlemmer did not think that inhalation of bacterium termo had given any satisfactory results, but believed the study of inoffensive micro-organisms might provide new methods of dealing with digestive troubles. Considering that one single bacterium of vinegar can destroy, in twenty-four hours, a hundred times its weight of alcohol, there is in this, perhaps, a powerful agent for dealing with functional disorders. In respect to the danger of contracting phthisis at thermal stations, he thought this had been exaggerated. The risk of contagion arose solely from the sputa, and, after all, people did not, and as a rule could not, spit in the springs. In conclusion, he urged that to the antiseptic qualities of mineral waters might be attributed in part the good results achieved, and wished that the therapeutic effects of various microbes on functional disorders could be more carefully studied. Dr. Eugenio Fazio of Naples gave

Digitized by Google

some account of his researches in the same direction with regard to the mineral waters of Italy. These have been fully reported in the *Giornale Internazionale delle Scienze Medicale*, published at Naples, and Signor Fazio, who sat at the presidential table, was congratulated by the Congress on his methodical and scientific methods of proceeding. He gave illustrations of the sort of pipettes that would best secure samples of water free from outside contamination.

Subsequently Mr. Adolphe Smith opened a discussion on the necessity of Improved Sanitation at various Health and Winter Resorts. He trusted the Congress would not misunderstand the object he had in view; his interests were not connected with those of any locality or nationality. This was an international congress; its sole object was to guide, in a scientific manner, those who suffered so that they might soon be cured; and this must be done on purely scientific grounds, without stopping to consider for a moment the interests of any particular district. He was willing to assent to the asserted inferiority of the English climate; but unfortunately a great number of English patients would not repair to the Continent because they feared to encounter the bad sanitation, especially of the French, Spanish, and Italian so-called health resorts. It was only necessary to compare the death-rates to show the appalling difference that existed. In England, at seaside and health resorts, and in spite of the presence of numerous patients, there were death-rates of 12, 13, and 14 per 1000. A small town in a healthy position, where there were no factories, no accumulations of poor people, but for the most part lodging-house keepers and people fairly well off, should have a death-rate below 15 per 1000 per annum. But he had found in France and elsewhere that the death-rate in such places amounted to 22, and in one case to even 28, per 1000. This was all the more remarkable as there were fewer children in France. With the same proportion of children as in England the mortality in France would be still higher. The reason for this distressful state of affairs was not far to seek. Even to-day new houses were in course of construction with cesspools placed under the front sitting-room, so that they could be easily emptied from the street. The closets were constructed with soil pipes so large that it was impossible to cleanse them; there were no traps, and practically nothing to prevent cesspool gases entering the house. In the kitchens the leaden pipes went straight to the sewers without trap and interception. The houses were simultaneously permeated with sewer air and the emanations from the cesspool. The patient while he was out of doors enjoyed a much better climate than in England. But what was the good of a pleasant walk in the sun for three or four hours if, during the remaining twenty hours, the patient was condemned to breathe sewer air? He could understand that municipalities should hesitate to build large sewers and adopt vast expensive schemes of drainage; but domestic drainage could be very much better managed and at little or no expense. In England, in some health resorts, it was proposed to examine lodging-houses and hotels, and give diplomas as to their sanitary condition, so that visitors might have the option of selecting for residence only such places as were certified to be in a healthy condition. THE LANCET had taken an active and successful part in this campaign, and it served to arouse public opinion. Could not something similar be done on the Continent? Then there was nothing to prevent the letting of rooms where there had been cases of small-pox or scarlet fever, and where no measures of disinfection were applied. Finally, in towns where a good public water-supply existed, he found the inhabitants still supplying their lodgers with contaminated water taken from private wells. In conclusion, he felt convinced that in many health resorts of France, Italy, and Spain, the death-rate might be reduced to the extent of 40 or even 50 per cent., if a proper system of public and domestic drainage were introduced, if a supply of pure water were rendered obligatory and all private wells closed, and, finally, if all persons suffering from infectious disease were isolated and their rooms rigorously disinfected.

Several delegates rose to explain that the condition of their respective towns was not so bad as in the picture Mr. Smith had drawn. M. Labat wanted to enter a protest that it was not to be supposed that everything was perfect in England and everything was bad in France. At Manchester, at Glasgow, he had found a high rate of mortality and some dreadful slums, and he had even discovered a dirty street in Ventnor. Other speakers thought that the giving of diplomas would cause so much quarrelling and so much disturbance as not to be practical. In France the landlords could not be made to do their duty except by the force of the law, and hopes were expressed that the new Parliament would find time to legislate on the matter. M. de Valcourt said the Congress should feel indebted to Mr. Smith for having introduced a subject in which they were all so deeply interested. At Cannes they had to thank the English for what improvements had been realised. But for British tenacity nothing would have been done. A system of diplomas had been introdced at Cannes, but this was principally among the English, who sent their sanitary engineers over to see that their villas were properly drained. The high mortality occurred in the summer months among the children of the native population who lived under less favourable sanitary conditions.

Mr. Adolphe Smith, in reply, said he was just as anxious to save the life of a native child as that of a rich visitor. A high rate of infant mortality was a sure sign of bad sanitation. He willingly associated himself with the protest made by M. Labat. Everything was not perfect in England, and he had spent the last ten years of his life denouncing the bad sanitary condition of various places in Great Britain. Nowhere in Europe had he seen sights more depressing than in the slums of Glasgow. He had examined the flush tanks introduced to cleanse the sewers of Nice, he knew that sanitary bureaux had been installed in various French towns, and acknowledged that some progress was made. This was not, however, the point he wished to raise. He repeated that in small towns where there were no slums, no factories, no overcrowding and misery, the death-rate should be, and in England actually was, below 15 per 1000. On the Continent, where the population was more sober, where there was a smaller proportion of children and a very much better climate, but where in every other respect the same conditions obtained, the mortality, instead of being below 15, was often considerably above 20 per 1000. This was mainly due to sanitary defects which the members of the Congress could materially help to efface if they would take this cause energetically in hand.

On the following day (Tuesday) the Congress went to Enghien and examined the thermal establishment and the celebrated sulphur waters of that pleasant Parisian suburb. They were well received by the Municipality, and entertained to a lunch. On Wednesday the Congress discussed technical details as to the administration of baths, the pulverisation of waters for inhalations, &c.

Dr. de Rouse, the general secretary of the Congress, read a paper on the Utility of Hydrothermal Treatment of serious Utero-ovarian Complaints both before and after surgical operations; and, in the evening, entertained to dinner a number of foreign delegates. Very cordial speeches were interchanged, and the foreign delegates warmly thanked Dr. de Rouse for having afforded them so pleasant a means of establishing intimate international relations.

Thursday morning was devoted to the discussion of the Therapeutic Application of Mineral Waters. The want of better comparisons between the various waters, and of general directions as to when they should be prescribed, was acknowledged by several speakers. Then the Congress debated on the question of including, as part of medical education, a course of lectures on the use of mineral waters and thermatology generally. Dr. Winternitz said that in the cliniques each person would have his own idea, and the discussion should be limited to the teaching of hydrology. He would propose that a special station should be created for the study, both practical and theoretical, of hydrology. The Belgian delegates complained that in their country nothing of the sort was taught, and this often placed the medical practitioners at serious disadvantage. Sometimes they only learnt from their patients what were the special advantages of various thermal and health resorts. A resolution was passed demanding the appointment of a commission to investigate the feasibility of altering the curriculum of medical studies and perhaps of creating chairs of climatology and hydrology in the various universities. The Congress also voted that in the meanwhile it was desirable that a few questions on these subjects should be introduced in the examination papers which medical students had to answer.

After visiting the Museum of Hygiene established by Dr. Proust at the Academy of Medicine, the Congress held its final sitting. The principal discussion related to the

Digitized by Google

next place of meeting. There were two invitations—one from Belgium and the other from Italy. The Belgian delegates pleaded with great energy and humour for their own country, while the Italians showed themselves equally anxious to secure the honour in favour of Rome. The Congress greatly enjoyed this tournament, and then proceeded to vote by ballot. Rome headed the poll by a large majority. The next, which will be the third, International Congress of Hydrology and Climatology will be held at Rome three years hence. After this decision, the Congress, having concluded its labours, adjourned amid cordial salutations.

After visiting the chemical and pharmaceutical section it was but natural to glance at exhibits of perfumery and articles for the toilet. The connexion between dress and health is better recognised every day, and I was anxious to see how far the French perfumer had imbibed these new doctrines. The result of the investigation was a complete disappointment. In the exhibits of hair-dressing it must be gratefully acknowledged that occasionally the principles of art have triumphed over the follies of fashion. On the other hand, not only are the laws of health neglected, but no care seems to be taken to preserve even the hair itself. Though little or nothing is known as to how the hair can be made to grow by artificial means, still the principles that govern its natural growth are obvious enough. Hair comes as clothing to protect the skin from the atmosphere or the sun, and will not grow so well, and perhaps not at all, on heads that are covered by unventilated hats. When women wore large chignons or piled up their hair in giant masses on the top of the head they had a tendency to become bald. These are self-evident facts, yet in the hair-dressing sections and in the millinery sections of the Exhibition I did not detect any attempt to act according to these principles. Originality, novelty, fashion, these were the only thoughts of the exhibitors. Sometimes they were actuated by a higher sense of art, but science has not yet influenced the exhibitors who dress the hair and make coverings for the head. In the perfumery section there are any number of hair washes and hair restorers, but nowhere anything new. No guarantee is given that lead, mercury, and other poisons do not constitute the active principle of these "restorers." The elegance of bottles in which they are exhibited, and the extravagant charge made for compounds that literally cost only a few farthings, are the chief attractions which ensnare an ignorant public. With mineral poisons the colour of the hair may be temporarily restored, but the constant use of these toxic substances is not likely to prove beneficial to the general health. Of more use are the various waters exhibited in the perfumery section used for dental purposes. Most prominent among these is the Eau Dentifrice du Docteur Pierre, which for fifty years has maintained its popularity. This exhibit is *hors concours;* a fact that is not surprising, considering that the firm has already received seven bronze, three silver, and seven gold medals. The advantage which Dr. Pierre claims for his dentifrice is absolute freedom from acids and aromatic and astringent qualities. Perhaps the exhibits of the raw materials used in perfumery found the most interesting feature in this section. Many of the largest firms from Grasse, notably Roure Bertrand et Fils, *hors concours* and member of the jury, and M. Cheris, sent specimens of essences, &c. The latter has an interesting series of photographs of his flower fields and his workers at Grasse and in Algeria. The hundreds of workmen and women employed in making scent, the mountains of rose leaves stored in huge barns, give an idea of the large share scents have in the pleasures of life. The oils and essences used by Piver, who has received the grand prix, are also close at hand; and some of the larger French perfumers have little drawing-rooms where there are fountains of scent, rich drapery, highly decorated shelves loaded with various bottles, jars, and art-painted satchels. When, however, I inquired from the graceful assistants who are there to extol the virtues of the perfumes if they had any antiseptic soap, I was greeted with an expressive look of horror by those who understood my question, for some of the assistants did not even know what I meant. How could I, in the midst of so many elegancies, refinements, and pleasures of life introduce a thought recalling the odours of the hospital, the agonies of disease and death? In self-defence I pointed to Rimmel's stall, where there is at least some coal-tar soap and some eau de Cologne, and some perfumed sawdust, that are recommended not so much as perfumes, but because they give off some oxygen, and therefore render the atmosphere purer. But then Rimmel is half an English firm; and Englishmen, according to the French tradition, are always committing some extraordinary and extravagant eccentricity. Under the cover of this excuse I beat a retreat from the perfumery section. The class abounds in luxury and in things of beauty, but there is little or no science. It is a triumph of coquetry over hygiene. The French have certainly not realised so well as the English that the arts of the toilet may be so combined with the care of cleanliness in such a manner as to ensure a better preservation of health; and this so intimately as to render it difficult to draw the line between the two. Here the French perfumers miss a good opportunity of raising their trade to a higher level. With thyme and other aromatics the antiseptic principle may be associated with a pleasant perfume, and thus two objects served at one and the same moment. This has been better understood by the State Perfume Distillery of the Principality of Monaco, which sends to the Exhibition some very agreeable antiseptic scents to be mixed with bath water.

Paris, Oct. 15th.

HOTELS.

(BY OUR ROVING CORRESPONDENT.)

(Concluded from page 761.)

I HAVE incidentally mentioned the effluvia of an hotel. These are chiefly due to humanity, cooking, tobacco, and drains, and in an average hotel the admixture of these four ingredients is, I should imagine, very tolerably equal. It is not necessary to dwell at length on the so-called "sanitary arrangements" of hotels, especially of continental hotels. These arrangements are, as a rule, execrable; the closets are often of the worst type, the supply of water is generally deficient, and the sanitary offices practically always ventilate into the corridors or shafts of the building. In designing an hotel provision ought to be made for placing closets and sinks in turrets approached by properly ventilated lobbies, so that the impregnation of the main building with sewer air may be a little less certain than it is at present. The pig if he has a chance goes outside his sty to obey the calls of nature, and it is only since man has given up following this very salutary example that sewer air has become his *bête noire* and the staple of his conversation. In big country hotels there ought to be (as there is in every country house) proper and ample accommodation provided in the gardens (approachable by a covered corridor if necessary). In this way the strain put upon the internal accommodation would be lessened, and the indecency experienced in a big Swiss kurhaus of a mixture of both sexes "waiting their turn" in the corridors would be avoided. Certainly a gentleman's "garden" ought to be provided as one of the sanitary accessories of an hotel, and it is probable that, properly managed, a similar arrangement would be welcomed by the ladies also. It is inconceivable to what extent this blind and dangerous practice of keeping "sanitary offices" within the walls of the main building is carried. Quite recently I visited one of the best known show places in Switzerland—the top of a mountain to which a railway brings hundreds of tourists daily during the season. Arrived at the summit, luncheon was necessary, and for luncheon a visit was paid to one out of several big hotels. This hotel, built in a place where the price of land can hardly be excessive, was of the usual type, four or five storeys high, with a central staircase and shaft running from the entrance hall to the roof. The entrance hall simply reeked of paraffin and ammonia *plus* hotel. The paraffin came from the lamps, the ammonia from the closets, which opened directly into the central hall. These closets communicated direct, without traps, with cesspools which received the slops and excrement of this huge establishment. To step from the pure air of the mountain top to the fearful atmosphere of this hotel was calculated to impress the mind of one who, having travelled to a spot where the air should have been absolutely pure, found that he was to run no small risk of being poisoned while he ate his lunch. At luncheon one could not but be impressed with the anæmic condition of several of the waitresses, and this was probably accounted for by the insanitary condition of the house.

In the present day, hotel advertisements generally lay

Digitized by Google

stress on the fact that there are "lifts," a monosyllable which lets in a flood of light on the general plan of the building, and indicates with absolute certainty that the area of the building is too small for the population it is designed to accommodate. Possibly some day we may have hotel advertisements couched in some such terms as these, "This establishment, standing in extensive pleasure-grounds, has been designed on the model of a luxurious country house. The main building is only two storeys high, and has been so designed that all the bedrooms may be easily reached without any undue effort. The sanitary offices are detached from the main building. The public rooms are also detached, but they are central, equally accessible from all parts of the house, and so arranged that the smell of the kitchen cannot possibly prove an annoyance." It is needless to say that every country hotel ought to stand in sufficient ground to enable it to be independent of any public sewer, and to deal with its own refuse in a manner which shall ensure the safety of the guests, render the soil increasingly prolific, and prove a source of profit to the landlord, rather than a perennial expense and nuisance.

Leaving the question of general design, I shall now consider some of the details of hotels. Thick parti-walls and double doors are absolutely essential to ensure the quiet of the guests. The bedrooms provided with these requisites should be of a convenient form. On the Continent the hotel bedroom is generally too long and too narrow. The window is often too small, and so heavily and ridiculously upholstered as to reduce its light-giving power to a minimum. This arrangement ensures that the end of the room farthest from the window is nearly always dark, and as the looking-glass is placed against one of the side walls, the difficulties of the toilet are very great. The bedrooms are often needlessly high, and not unfrequently there is a space of two feet or more between the ceiling and the top of the window. In "summer hotels" the bedrooms have no chimneys, so that it is impossible to get a current of air through them without opening the door, and the opening of the door generally means the admission of suffocative vapours from the corridor. Every hotel bedroom should have a covered balcony so arranged that in winter it can be enclosed by outside windows. A balcony is in summer a very pleasant addition to a room, but as an adjunct to a hotel bedroom it is necessary, in order to afford the occupant a place for shaking and brushing dusty clothing—a process constantly necessary for a traveller, but one which cannot be performed except in the open air. It is as well to state that the balcony is more common in continental than in English hotels. The thoroughly well-designed hotel bedroom, carefully "fitted" rather than furnished with an eye to the comfort and well-being of the occupant, is one of those things which may be found when upholsterers do not happen to be the chief shareholders in hotel companies. In one particular, hotels on the Continent are uniformly first-rate, and that is in the excellence of the beds. These are always comfortable and very superior to the beds which are found in English hotels. Of the rest of the furniture, the less said the better; but I cannot refrain from commenting on the perverted genius of the man who invented the chest of drawers and washstand in one, so designed that one's clean shirts are almost inevitably invaded by a flood of soapsuds. Your correspondent has been travelling for twenty-eight days, and he has paid 75c. per diem, or a total of 21 fr., for the tin vessel, and some two gallons of water, which the Englishman (especially when engaged in active exercise) has the arrogance to demand for the purpose of cleansing his skin. One need not grumble at the sum paid, but certainly one has a right to grumble at the difficulty often experienced in getting this customary sitz bath. Perhaps, when the Germans have written a few more thousand treatises on "Haut Cultur" these arch-pedants will begin to wash, and hotel proprietors will provide as a matter of course that which is now wrung from them with difficulty. The writer can only recall one hotel in which he has found a sitz bath supplied without asking, and that hotel was at Malta, and it is probable that the landlord had been drilled in this particular by officers of the English garrison.

A few words in conclusion as to hotel feeding. First one would ask whether the time has not arrived for the abolition of the huge Swiss *table-d'hôte* in its present form. The greatest good is got from a summer holiday by spending all day and every day in the open air, and it is extraordinary that people should submit to have their pleasures curtailed by the necessity of dining at a fixed hour, and that often when the hot summer day is at its best. When the noisy dinner-bell of the Swiss hotel kurhaus begins its intolerable clang, and the guests, dragooned by a pompous head waiter, begin to fall into line in the huge comfortless dining-room; and when the soup is served with a sort of military precision at the stroke of a bell, it is difficult to repress the thought that one is the inmate of some charitable institution, and this thought will be intensified if the soup should prove to be a pultaceous gruel, and if, being Saturday night, the English chaplain is making a tour of the room with a view of getting recruits for to-morrow's choir. "It will be something like this in the workhouse, I suppose," is the thought that rises to the mind, but accompanied by the blessed reflection that in "the house" we shall not have to pay five francs a head. The monster *table-d'hôte* is objectionable also because of its tediousness, the intolerable heat and noise, and the risk one runs of being placed in close proximity to people who, from one cause or another, are not congenial. It would be better, I think, from every point of view, to adopt the English plan, and serve a house dinner at a fixed price between certain hours. This dinner, if served at small tables, would allow the guest some degree of liberty as to the time of his meal and the selection of dining companions, and ought to allow of more variety in the *menu* than is possible at the ordinary *table-d'hôte*. Of hotel feeding I have written in previous years, and I am rather afraid that free trade makes a man an epicure. In London we are fed upon selected food drawn from every country in the world, and as a consequence we have a variety of fish, flesh, fowl, farinas, fruit, and vegetables which is to be met with nowhere else. In the days of the Tudors we had the reputation of being the best fed nation in Europe, and there can be little doubt that we deserve that reputation still. This is a matter for congratulation; but, nevertheless, we must admit the drawback that the Englishman on his travels will have to submit to the minor hardship of paying very dear for food which by no means unfrequently seems to him to be very second rate.

SOCIETY OF APOTHECARIES OF LONDON.

THE MEDICAL ACT OF 1886 AND THE TITLE OF L.S.A.

Mr. J. R. UPTON, the clerk and solicitor of the Society of Apothecaries, has forwarded to us the following statement, with a request that it might appear in our columns.

A misunderstanding appears to prevail on the part of persons passing the Qualifying Examination held by the Society of Apothecaries of London, that they are entitled to ask the Medical Council to register them under a title which does not exist—namely, that of Licentiate in Medicine, Surgery, and Midwifery. The Society desires, therefore, to publish an authoritative statement which it is hoped may finally put an end to the misunderstanding, and so avoid further trouble to the Medical Council, the Society, and the Licentiates themselves. If the Licentiates would read the Medical Acts they could never fall into the error which it is the object of this statement to correct. In the first place, no Medical Act has ever sought to define what was the meaning of the titles conferred by the various licensing bodies. The Medical Act of 1858 merely enacted that a person must be registered under one of the titles scheduled to that Act, and that he must only practise what that title allowed of his doing. But the Act of 1858 did not, for example, define what rights the title of L.R.C.P., M.R.C.S., and L.S.A. respectively conferred. That could only be ascertained by reference to the Charters or Acts under which the various licensing bodies existed. Only those who were familiar with those Charters or Acts could say whether a Member of the College of Physicians could legally practise both medicine and surgery, or whether a Licentiate of the Society of Apothecaries could only practise medicine. Without this knowledge no one, by mere intuition, could say whether an L.R.C.P. could practise surgery, or an L.S.A. could not; neither title using words to imply whether the power to practise surgery was conferred or not, and the title L.S.A. on the face of it not even implying the power of practising medicine. The Act of 1858 unintentionally originated or perpetuated an abuse in the fact that a qualified or registered medical man frequently ignored the limitation imposed on him by his licensing body and by the Register, and practised one or other of the subjects for which he had no registrable qualification. The Act of 1886 (so far as its provisions in the above respects are under discussion) was brought in to put an end to this state of things. Like its predecessor of 1858, it did not interfere with or alter the titles which the various bodies had power to confer, but it effectually stopped any medical title being obtained except on conditions which conclusively established that the holder had proved his proficiency in medicine, surgery, and midwifery. To illustrate this, it may be stated that since the passing of the Act of 1886 it is not of necessity, but by choice, that a person passing the examination of the Conjoint Board of the Royal Colleges has himself registered under the diplomas of both Colleges. Provided he has passed the Conjoint Examination, he may, if he please, get on the Register either as L.R.C.P. or M.R.C.S.

Although the whole point under discussion might be said to be one of interest only to the medical profession (the public never, or practically never, consulting the Medical Register either before or since the Medical Act of 1886, or inquiring what titles a medical man possesses, or what functions they empower him to discharge), it is important to observe that it is only because medical men before 1886 knew that L.S.A. could only practise medicine that they have imported into the title words which are not to be found in it. It cannot be expected that in the space of three years everyone should know that that title, if obtained after 1886, implies a great deal more than it did formerly, but in time this will have become as thoroughly known as gradually after 1815 it became known that L.S.A. meant a Licentiate in Medicine. The reason why it was gradually known after 1815 that the title L.S.A. entitled the holder to practise medicine was because it was so expressed in the diploma then granted by the Society, and that the contents of such diploma became generally known. But in the same manner, now that the Society's diploma expresses on the face of it that the holder can legally practise medicine, surgery, and midwifery, this fact will in time be equally well known, and, indeed, far more rapidly and completely, because, if the present diploma did not show on the face of it that the conditions of the Act of 1886 had been fulfilled, it could not be put on the Register at all, and this must soon become a matter of general notoriety.

Enough has been said to fully justify the Society remaining passive, even if it had not attempted to get the title of its Licentiates altered when the Act of 1886 was being passed. But it is a matter known to all who had to do with that Act before it passed (and the Society was allowed as much indulgence as any other medical body in approaching the Government during the progress of the Bill) that the Vice-President of the Privy Council absolutely, and no doubt wisely, declined to allow the principle of the Act of 1858, as above explained, to be interfered with. The Society, nevertheless, during the present year submitted through its representative, Mr. Brudenell Carter, to the Medical Council the draft of a Bill to be laid before Parliament for (among other things) altering the title of its Licentiates obtained after 1886. The Medical Council declined to countenance such a proposal, and the Society therefore abandoned it; and unless any general scheme should be formulated, either by Government or by the Medical Council, for dealing with the question of medical titles, the Society will not of its own accord take any further step in this direction. Public bodies who have appointments to confer are fully aware of the qualifications conferred by the title of L.S.A. granted since the Act of 1886, the Society having never lost an opportunity of satisfying them on the subject.

POSTSCRIPT.—Since the above statement was forwarded for publication the Society finds that a memorial is about to be presented to the Medical Council by many gentlemen who have obtained its licence under the provisions of the Act of 1886, asking the Council to deal with the question under discussion. The Society, it is needless to say, has no wish to discourage such a memorial, and would point out that in the last paragraph but one of the statement it only explains that after what has already taken place it could not, as one of the representative bodies on the Council, again initiate such a movement. The decision of the Medical Council at its last session rested on a basis which, however unacceptable to those who differ from it, is intelligible—namely, that while, for example, the titles of the diplomas of the Colleges of Physicians and Surgeons identify the holder with the Licensing Body which granted them, the new title suggested for the Licentiates of the Society of Apothecaries would be entirely disconnected, or be liable to be disconnected from the Society, and might therefore even imply that it was a title granted by some other body.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF INSPECTORS OF THE MEDICAL DEPARTMENT OF THE LOCAL GOVERNMENT BOARD.

On the Sanitary Condition of the Buckingham Rural District, by Dr. GRESSWELL.—Dr. Gresswell, who has for some time been giving occasional services to the Local Government Board, enters into a detailed description of the sanitary state of this rural district, which contains a somewhat stationary population of about 9800 people, chiefly engaged on the land, and living in scattered hamlets and villages. The dwelling accommodation has received some local attention; but there still remains much to do in the way of rebuilding and repairing; and there is much lack of that which is proper from both a structural and a sanitary point of view in the matter of the disposal of excreta and refuse. Drainage arrangements are also extremely defective, varying as they commonly do from the mere slop-hole or ditch to drains of bad construction, which admit of being blocked or of otherwise causing nuisance. Such sewers as there are appear to be mere highway drains, but they seem at times to receive privy contents, slaughter-house drainage &c. Water comes from a number of sources, including wells which are imperfectly protected from surface soakage, and are sunk in a soil liable to contamination; and a long account is given of the various available sources of supply, which shows the need that exists for improvement and watchfulness in this respect. Typhoid fever, as might have been expected, is of frequent occurrence, and diphtheria is also far too common. The rate of mortality from respiratory diseases is also excessive, this result being in part, if not largely, due to the damp and ill-ventilated condition of the dwellings. The occurrences of infectious diseases have often been in groups, and have been due to such conditions as local pollutions of water; and Dr. Gresswell, in reviewing this part of his subject, says that the circumstances discovered and narrated afford a strong indication that the sanitary authority have not properly exercised the functions imposed upon them by the Legislature. They have hesitated to use the powers they possess; they have made no bye-laws; they have no means for the proper isolation of infectious diseases; and the advice of their medical officer of health goes unheeded. This officer also receives no encouragement to attend the meetings of the authority, at which they should, properly speaking, take counsel of him. Perhaps the strongest condemnation of a system which imposes on a body of people mainly elected for Poor-law work, that of caring for the health of the community, is contained in the statement that at their monthly meetings they are said to give thirty minutes—or six hours in the course of the year—to the sanitary aspects of their district, and that even this amount of time has recently been sensibly curtailed in order to give attention to the subject of allotments. We fear the Buckingham guardians are not the only ones who thus postpone their sanitary work until the end of a Poor-law meeting. It often happens that but few remain at the Board, since it is market day; and thus when important health considerations come forward they get postponed again and again until they are practically forgotten.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Gateshead Urban District.—Dr. W. Robinson takes occasion, in his annual report for 1888, to advert to the evils of overcrowding in Gateshead, and to point out the methods by which this tends to increase mortality. At the same time he is able to prove by comparative statistics of the last two quinquennial periods that 1884–88 shows a reduction of death-rate from all causes, from zymotic diseases, and as to the proportion of infant deaths per 1000 to registered births, and this although the number of persons per acre had increased from 21·3 in 1881 to 26·0 in 1888. Last year's general death-rate was 17·0 per 1000 in an estimated population of 81,303. The isolation hospital is stated to have again proved of considerable value to the borough, but the number of admissions during the year was only twenty-two in all. The water-supply of Wrekenton, Blue Quarries, and Sheriff Hill is still of a very unsatisfactory character, and the Corporation are met by the difficulty that these places are situated at an altitude above highwater mark, at which the water company is exempt from any liability to provide a supply. Happily the old large open middens are disappearing, although the process is a slow one. Indeed, on the whole steady improvement seems to be going on in Gateshead, which is described as essentially a "workman's town"; and regular sanitary work is systematically in progress.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN twenty-eight of the largest English towns 5642 births and 3201 deaths were registered during the week ending Oct. 12th. The annual rate of mortality in these towns, which had been 17·9 and 17·6 in the preceding two weeks, further declined last week to 17·5. During last quarter the death-rate in these towns averaged 18·6 per 1000, and was 1·6 below the mean rate in the corresponding periods of the ten years 1879-88. The lowest rates in these towns last week were 9·3 in Cardiff, 12·3 in Bristol, 13·8 in Derby, 14·3 in Nottingham, and 14·9 in Leicester. The rates in the other towns ranged upwards to 25·6 in Newcastle-upon-Tyne, 27·6 in Sunderland, 28·0 in Preston, and 32·7 in Plymouth. The deaths referred to the principal zymotic diseases, which had been 529 and 403 in the preceding two weeks, further declined last week to 352; they included 116 from diarrhœa, 65 from scarlet fever, 55 from diphtheria, 43 from "fever" (principally enteric), 41 from whooping-cough, 32 from measles, and not one from small-pox. These zymotic diseases caused no death last week in Huddersfield, and the highest death-rates in Preston, Sunderland, and Plymouth. The greatest mortality from

Digitized by Google

diarrhœa occurred in Preston, Newcastle-upon-Tyne, and Wolverhampton; from scarlet fever in Salford, Leeds, and Plymouth; from "fever" in Plymouth; from whooping-cough in Oldham; and from measles in Preston and Sunderland. The deaths from diphtheria included 35 in London, 4 in Manchester, 3 in Salford, and 3 in Liverpool. Small-pox caused no death in any of the twenty-eight great towns; and no small-pox patient was under treatment at the end of the week either in the Metropolitan Asylum Hospitals or in the Highgate Small-pox Hospital. The number of scarlet-fever patients in the Metropolitan Asylum and the London Fever Hospitals at the end of the week was 1342, against numbers increasing in the preceding fifteen weeks from 559 to 1299; 177 cases were admitted to these hospitals during the week, against 166 and 149 in the previous two weeks. The deaths referred to diseases of the respiratory organs in London, which had been 142, 189, and 225 in the preceding three weeks, further rose last week to 264, but were 28 below the corrected average. The causes of 63, or 2·0 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Birmingham, Leeds, Nottingham, Leicester, and in five other smaller towns; the largest proportions of uncertified deaths were registered in Hull, Halifax, Liverpool, Preston, and Bolton.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 18·8 and 18·6 per 1000 in the preceding two weeks, further declined to 18·3 in the week ending Oct. 12th; this rate exceeded, however, by 0·8 the rate that prevailed during the same week in the twenty-eight large English towns. The rates in the Scotch towns ranged from 10·6 and 13·4 in Greenock and Dundee to 21·6 in Glasgow and 23·3 in Paisley. The 469 deaths in the eight towns showed a further decline of 8 from the number in the previous week, and included 19 which were referred to diarrhœa, 14 to whooping-cough, 13 to diphtheria, 7 to measles, 6 to scarlet fever, 5 to "fever" (typhus, enteric, or ill-defined), and not one to small-pox; in all, 64 deaths resulted from these principal zymotic diseases, against 74 and 69 in the preceding two weeks. These 64 deaths were equal to an annual rate of 2·5 per 1000, which exceeded by 0·6 the mean rate last week from the same diseases in the twenty-eight English towns. The fatal cases of diarrhœa, which had declined in the preceding four weeks from 38 to 16, rose again last week to 19, of which 8 occurred in Glasgow, 4 in Dundee, and 3 in Edinburgh. The 14 deaths from whooping-cough were within one of the number in the previous week, and included 9 in Glasgow and 3 in Paisley. The 13 deaths referred to diphtheria corresponded with the number in the previous week; 6 were returned in Glasgow, 6 in Edinburgh, and 1 in Leith. Of the 7 deaths from measles, 3 occurred in Glasgow, and 2 in Aberdeen. The 6 fatal cases of scarlet fever included 2 in Glasgow and 2 in Perth; and 4 of the 5 deaths from "fever" occurred in Glasgow. The deaths referred to acute diseases of the respiratory organs in the eight towns, which had been 66, 89, and 99 in the preceding three weeks, declined again last week to 87, and were 21 below the number in the corresponding week of last year. The causes of 41, or nearly 9 per cent., of the deaths registered in the eight towns were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 31·5 and 26·2 per 1000 in the preceding two weeks, further declined to 23·2 in the week ending Oct. 12th. During the last quarter the death-rate in the city averaged 24·0 per 1000, the mean rate during the same period being 15·8 in London and 16·0 in Edinburgh. The 157 deaths in Dublin last week showed a further decline of 20 from the high numbers returned in the preceding two weeks; they included 14 which were referred to diarrhœa, 7 to "fever" (typhus, enteric, or ill defined), 2 measles, and not one either to small-pox, scarlet fever, diphtheria, or whooping-cough. Thus the deaths from these principal zymotic diseases, which had been 31, 30, and 23 in the preceding two weeks, were again 23 last week; they were equal to an annual rate of 3·4 per 1000, the rate from the same diseases being 1·5 in London and 2·0 in Edinburgh. The deaths attributed to diarrhœa, which had been 23 and 12 in the previous two weeks, rose again last week to 14; the 7 deaths from "fever" corresponded with the number in the previous week. The deaths of infants showed a marked decline from recent weekly numbers, while those of elderly persons corresponded with the number in the previous week. Two inquest cases and 3 deaths from violence were registered; and 48, or more than a quarter, of the deaths occurred in public institutions. The causes of 18, or more than 11 per cent., of the deaths in the city were not certified.

THE HIGH DEATH-RATE IN RUSSIA.

Dr. Leinenberg of Odessa publishes in the *Internationale Klinische Rundschau* a lengthy article on the mortality in Russia, which is full of interest for the statistician. He says that in the number of births alone Russia ranks first of all European States, as they annually amount to no less than 48·8 per 1000 of the population. The latter would consequently grow with abnormal rapidity, if an enormous mortality did not make this impossible. This mortality is, according to Janson, 37·3 per 1000, while the Statistical Central Committee reports it at 36·8 per 1000. As to the causes of such high figures, Dr. Leinenberg points out that they depend largely on high infantile mortality. He states that 104·8 boys are born to every 100 girls, and that amongst the Jews the proportion of boys born rises to 128·9 for each 100 girls. The mortality of boys, as of the male sex in general, is correspondingly greater than that of the female sex, in the proportion of 36·7 to 35·2. Of 1000 newly born children 263·4 die before they are a year old. This mortality in the first year of infancy is in the province of Novgorod 281 per 1000, and in the Rusk district of the province of Moscow it reaches the figure of 550·8 per 1000. Even this enormous number has been surpassed by the town of Irbit, which shows a mortality during the first year of life of 560·2 per 1000. The provinces of Ekaterinoslaw and Wilno are distinguished by the lowest infantile mortality, the figures mentioned in the report of the Statistical Central Committee being 139·7 per 1000 for Ekaterinoslaw and 118·9 per 1000 for Wilno. Comparing the infantile with the general mortality in Russia, the author points to the following two important statistical results. Children up to the fifth year of age form more than one-half of the deaths from all causes. Infantile mortality shows a tendency to increase every year. This great infantile mortality in Russia must be largely attributed to the want of proper diet and of sufficient care, especially amongst the agricultural population. In summer, which is the time when nearly all the children die in the country, the parents are in the fields, leaving their infants at home with no supervision and without sufficient food. This sometimes leads to strange and sad accidents, as in a case mentioned by Giljarowsky, in which pigs devoured the buttocks of a child which had been left alone at home for a considerable period. Griasnoff attended a child, which under similar circumstances had been attacked by goats, and had lost every finger on both hands. Dr. Leinenberg also goes on to speak of the health of those who have passed the crisis of the fifth year. Of 1,568,315 boys born in the year 1858, only 750,622 were alive in 1879, and when out of this number 272,974 were examined for the purpose of military conscription, 58,824 men—i.e., 21·5 per cent.—were found to be suffering from various incurable or chronic diseases, and had consequently to be returned as unfit for military service. So that of all boys born in 1858, 47·8 per cent. reached their twenty-first year, but only 37·6 per cent. preserved good health.

THE SERVICES.

ARMY MEDICAL STAFF.—Surgeon-General Jeffery Allen Marston, M.D., C.B., F.R.C.S. England, is granted retired pay (dated Oct. 16th, 1889); Surgeon-Major Charles Healy is granted retired pay (dated Oct. 16th, 1889).

ADMIRALTY.—Royal Naval Artillery Volunteers (Liverpool Brigade): Surgeon Alfred Charles Edward Harris, F.R.C.S., to be Staff Surgeon (dated Oct. 9th, 1889); Surgeon Henry Briggs, M.B., F.R.C.S., to be Honorary Staff Surgeon (dated Oct. 9th, 1889); and George Herbert Pollard, M.B., C.M., to be Surgeon (dated Oct. 11th, 1889).

VOLUNTEER CORPS.—*Rifle:* The Queen's Rifle Volunteer

Digitized by Google

Brigade, the Royal Scots (Lothian Regiment): William Henry Miller, M.D., to be Acting Surgeon (dated Oct. 12th, 1889); 2nd Volunteer Battalion, the Royal Warwickshire Regiment: Acting Surgeon W. J. Pickup, M.B., to be Surgeon (dated Oct. 12th, 1889).

Correspondence.

"Audi alteram partem."

THE PRACTICAL ELEMENT IN MEDICAL EDUCATION.

To the Editors of THE LANCET.

SIRS,—A very few words from me will suffice to close, I trust, the controversy with my friend Mr. Wheelhouse, and will at the same time make it apparent that (as I assumed in my Leeds address) "we do not differ greatly in essentials." Certainly I could not possibly claim from anyone, thinking as he does, a more handsome concession than this: "I would rather go on as we are, greatly as I consider that our plan might be improved, than that we should go back to the old system of a five years' apprenticeship to one man or to one institution. I hold, and I have ever taught, that to go back to that system would be to waste, hopelessly and absolutely, three years of the very best part of every educational life." On the other hand, I am fully disposed, from my point of view, to concede that "the present system" is very far from being perfect; and if the Medical Council can devise a plan, consistent in any degree with what I have called "thoroughness," for grafting upon it a larger amount of such practical experience as can be obtained only, or best, in the homes of the sick, it will be a decided gain. My object was, and is, to maintain that "thoroughness" in the *method* of instruction is of more importance than extent in the *range*, as regards the number of cases seen, because clinical instruction, so-called, which is not thorough is even worse than useless, in respect that it inevitably begets, and perpetuates, bad habits both of diagnosis and of treatment. Hence I argued that it was much better to learn, clinically, a few things about disease well, than a great many things badly; and that in any case the much more thorough investigation which is at least possible in the clinique of a well-managed hospital forms a better foundation for practice than almost any amount of so-called experience attained under less favourable conditions. But I am very far from adopting the paradox attributed to me by Mr. Wheelhouse, that "half a dozen cases of pneumonia, or of Bright's, or any other diseases, studied ever so deeply, will stand instead of the practical ability to relieve a distended bladder, or to reduce a dislocated joint." On the contrary, I hold that these very surgical procedures eminently and peculiarly demand thoroughness in teaching certainly not less than the leading facts of medical experience; and the only question about them is, or ought to be, how in the case of the general practitioners of the future this thoroughness can best be secured. I do not think that in these particular instances it can best be secured, or indeed be secured at all, "at the commencement of professional study." All this, however, is matter for the General Medical Council, and I am very well content to leave it to them to arrange when, how, and by whom this kind of instruction is to be conveyed. I will only give, in conclusion, a small contribution out of my own personal experience, just in order to show that in this matter I am not speaking at random nor yet uttering "mere declamation." Although I never, even in the student days of long ago, was conscious of aiming specially at surgical practice, I had in the third year of medical study personally extracted more teeth and performed more venesections than I have ever even thought of doing since; and in the latter case far more numerically than all my pupils together have had a chance of doing for the last thirty years. But I have often since then been led to reflect, who was the better for that? Was the mechanical skill supposed to be attained in this rough-and-ready practice an adequate compensation for its roughness? During the same third year, or rather summer and autumn, I attended some scores, or, I believe, hundreds of cases in their own homes in almost every close and wynd in my native Edinburgh, from Holyrood to the West Port, and certainly managed to see (in a kind of way) almost all the common diseases (epidemic and other) under the nominal "covering" of a chief, but really almost uncontrolled. I am far from undervaluing this experience; but I have no doubt now that I made many mistakes, and might have adopted very "automatic" ways of dealing with disease but for the invaluable and long course of hospital experience which followed, and is not even yet completed. And for the great majority, who cannot in the course of events be expected to undergo a similar training *after* they go into practice, I hold that the hospital training of the student should, above all things, be *thorough*—"Non multa sed multum." But in nearly one hundred separate and carefully managed clinical conferences which go to make up our winter course, and half that number in summer, we do, I trust, in the Western Infirmary here get over a good deal more ground, even in respect of common diseases, than Mr. Wheelhouse, with his allusion to "half a dozen cases" &c., accredits us with doing. At all events, we do our best. It is for the Medical Council to say what more can be done, or attempted, in future; and so it be consistent with "thoroughness" of method, it will not only have no opposition from me, but the contrary.

I am, Sirs, yours truly,

Glasgow, Oct. 14th, 1889. W. T. GAIRDNER.

To the Editors of THE LANCET.

SIRS,—It is a hopeful sign of the times when one finds men like Mr. Wheelhouse and Dr. Clifford Allbutt discussing the vexed question of medical apprenticeship; but the curious part of it is that the question should require discussing at all. It is admitted on all hands that the hospital curriculum does not teach the embryo doctor the routine of private practice, or what our old friend *Mr. Punch* calls a good bedside manner, and, though it teaches him to talk learnedly about such diseases as locomotor ataxy or perityphlitis, which he may see once or twice in five years, it does not teach him to diagnose a case of measles or ordinary sore-throat; indeed, to him sore-throat is always "diphtheritic exudation." Why, in the name of common sense, should a lad of sixteen or seventeen, in our profession, not begin as he does in the law and every other profession and trade by mastering its details and all the thousand little things that go to make success in after-life. Years ago medical men were paid to teach a youth these little but useful minutiæ; now medical men have to teach, or *try to do so*, young men fresh from hospital who think they know more than those who have been successful in private practice for twenty years, and at the same time to pay them £80 or £100 a year for the honour and privilege of doing so.

Some time ago I was talking to the dean of a medical school, and this is the impression he left upon me: That those connected with medical schools make the laws relating to medical education; that if a lad was with a medical man, say two years, he would only need three in hospital instead of four; that this would mean a loss of £40 per student to the medical school; that therefore it is simply that the medical school wants the money that otherwise would reach the medical practitioner with whom the student was apprenticed. If this is so, here is the key of the position. I trust so selfish a policy cannot have foundation in fact.

It is not pleasant to engage an assistant who may be an L.R.C.P. Lond. and all the rest of it, and to find that old women have to correct him; that he rides a horse like a tailor, cannot dispense or fill up a vaccination book, advises paupers to have jellies made, and not to take 1*s.* 6*d.* port-wine, exposes females as they do in lock wards, drives your horse and trap into the ditch, and smashes it as it ought to be smashed, mistakes measles for syphilis and flea-bites for scarlatina, treats itch for a month with liquor arsenicalis; in fact, makes blunders that ruin his reputation and injure his employer, blunders he could not make if he were a pupil for even six months.

To return to the old system of five years' apprenticeship would be absurd; two years is quite enough (I did five, and I never regret it). And if a youth were made to learn practical pharmacy and dispensing during this time, and to pass an examination in it, instead of having to learn such trash as mechanics, he would be none the worse. More than this, two years' probation as an apprentice would show whether a lad was fitted for the profession; and if he were not, it would not be too late, as it is now, to begin one more congenial to his taste. He enters hospital when he ought almost to be at school, and is pledged to go on with

Digitized by Google

a profession in which he may be a failure, and thrown, his own master, on a world that he knows nothing about before his character is sufficiently developed to withstand its temptation; in fact, he has finished his curriculum very often while he is still *an infant* in the eyes of the law. The youth who can, after his curriculum is over, hang about hospital "until something turns up" is the exception. Most young men must necessarily go into provincial practice or as assistants, and if they only knew how much better salaries they can command if they know the ins and outs of private practice, if they have mastered its details—which they are too self-opinionated or too proud to do after they are qualified—they would themselves find the remedy; as it is, it strikes one they are in the hands of those who, like Shylock, want the extreme pound of flesh.

I am glad indeed to find Mr. Wheelhouse taking up the cause, and I trust he will go on with it until he has succeeded in improving the present admittedly imperfect state of medical education.

I am, Sirs, yours faithfully,

Sherborne, Oct. 12th, 1889. NATHANIEL EDWARD DAVIES.

To the Editors of THE LANCET.

SIRS,—Having read Dr. Gairdner's address at Leeds, as also Mr. Wheelhouse's letter in your last issue, I shall be glad if you will allow me as a general practitioner to say a few words. Dr. Gairdner speaks as a clinical teacher, and his remarks apply to strict clinical work rather than to general practice. Mr. Wheelhouse treats the subject from a broader point of view, and in maintaining the advantages of the early apprenticeship he has my entire sympathy. I think that every youth should be apprenticed for at least two years, during which time he will have the advantage of learning the routine of surgery work, and also be able to read up the elementary part of subjects he has to face on commencing his studies. I allude to the bones, chemistry, and materia medica. He will thus enter on his curriculum with an advantage not possessed by him who commences otherwise. He is just at the age to receive impressions which will last a lifetime, and erroneous ones will soon be knocked out of him when he comes into the hands of such men as Professor Gairdner at the bedside. As an apprentice he will acquire a knowledge of details which he will never forget, and which are unknown to those who merely attend at a dispensary. These details are too numerous to mention, but consist in a familiarity with drugs, dispensing, and an aptitude of examining and addressing a patient in a natural easy way. To gain the confidence of a patient is half the battle towards success, and this is not to be attained by strict clinical teaching. Again, I am quite sure that he who has served an apprenticeship is much more likely to benefit by clinical teaching, and in a better position to grasp the knotty points of a complicated clinical case than he who joins the profession without a preliminary training. As regards entering on a kind of apprenticeship after having attended lectures, such a procedure is putting the cart before the horse. I think Professor Gairdner and Mr. Wheelhouse are both correct in their ideas, and firmly believe that the youth who follows Mr. Wheelhouse's advice in the early, and Professor Gairdner's advice in the latter part of his studies, will make the best practitioner.—I am, Sirs, yours faithfully,

Oct. 15th, 1889. CYCLOPS.

To the Editors of THE LANCET.

SIRS,—Mr. Wheelhouse's contention is difficult to oppose if his premisses are admitted. May I point out the premiss that I think far too erroneous to be allowed to pass? Mr. Wheelhouse speaks of "*simple information*;" he says "*rudimentary knowledge* should be sought in the earlier years of studentship" (the italics are mine). The "simple information" he specifies is acquaintance with "the more common forms of ordinary illness," ability "to know measles from scarlet fever," &c. There can be no doubt that "rudimentary knowledge," "simple information," should be first learnt. But "the most common forms of ordinary illness" are among the most difficult problems of our art. What the student calls a "good case" of pleuritic effusion, ulcer of the stomach, cerebral tumour, compound fracture, &c., although of greater gravity, is yet infinitely more simple than a case of chronic rheumatism, recurrent headache, doubtful incipient phthisis, and the like. To track out the origin correctly, measure the importance of comparatively slight ailments, and treat them with the greatest amount of success, test the highest powers of the physician, although the prescribing chemist and the pupil who has been three months in a surgery can alike put up a bottle of medicine which will give temporary satisfaction. Simple things should certainly be first learnt; but it is hospital work that is simple, not private practice. I think every student after being qualified, not before, should pass a year or two as assistant to a general practitioner.

I am, Sirs, faithfully yours,

Oct. 14th, 1889. F.R.C.P.

THE ELECTRO-MAGNET IN OPHTHALMIC SURGERY.

To the Editors of THE LANCET.

SIRS,—Mr. Simeon Snell's remarks in your last issue concerning my article on foreign bodies in the eye are calculated very much to mislead. There is a kind of indirect inference that the use of the electro-magnet is not known here, or, at all events, is not duly appreciated, and that we still resort to what Mr. Snell disparagingly alludes to as "the crude methods of years gone by." I think that those who will read my paper carefully will not be thus deceived, and those who have followed my practice will admit that we are quite as alive to what is passing in the ophthalmic world here as they are in Sheffield. I used a magnet for the removal of particles of steel from the eye before Mr. Snell had probably entered the profession, and was the possessor of one of the first electro-magnets used in this country, some time before the somewhat inconvenient instrument which bears Mr. Snell's name was introduced to the notice of the profession. If I did not emphasise the use of the electro-magnet for the removal of pieces of steel from the iris, it was not because I do not believe it to be sometimes of value under these circumstances, but because my remarks were applying in a great measure to particles which are not influenced by magnetic attraction. The reasons why I did not use the magnetic probe in the special case mentioned in my lecture were because in the first instance the instrument was not within my reach, and in the second the piece was so firmly embedded in the iris, and this structure was itself so inflamed and adherent, that iridectomy, I felt, would probably be desirable under any circumstances. The case, indeed, was brought forward chiefly with a view to illustrate the great advisability of using anæsthesia in all these cases, and the danger that is incurred by neglecting this precaution. Had the patient been brought fully under the influence of chloroform, I have no doubt the fragment would have been readily enough removed with the forceps. Indeed, my own experience and that of others prove that it is precisely in these cases (where a piece of steel has become fixed in the iris, and that structure has become inflamed and adherent) that the magnetic probe gives the most unsatisfactory results, and by its failure frequently necessitates our having recourse to the "crude methods" to which Mr. Snell objects. Thus, in a paper[1] in the "Archives of Ophthalmology for 1888," giving Professor Horner's experience in the use of the electro-magnet, we find the following:—"In all six cases of metallic foreign bodies firmly lodged in the iris the magnet was indicated in only three of these, and in two only did it yield any result." And further on: "This agrees pretty well with Hirschberg's results, where, in the most impartial manner, only one case of extraction by the magnet is reported against five others in which extraction had been accomplished by means of the forceps."

Mr. Snell concludes his letter by reminding us that *his* observations on the magnetic needle were published some years ago. I do not doubt this, though I have never had the pleasure of reading them, and in any case I fail to see why others should be deterred from pursuing investigations in the same field of inquiry. Although it is now some ten or twelve years since I first made experiments upon this subject, and have used the magnetic needle occasionally ever since then, I fear neither Mr. Snell nor myself can claim the originality of the idea, which dates from a far more remote

[1] Dr. Neese: Contribution to the Magnet Operation.

Digitized by Google

period. After an experience in injuries to the eye which is probably not far short of your correspondent's, I may say, generally speaking, that I consider the electro-magnet a very much overrated instrument; for if it has saved some eyes in the hands of skilful operators, its extensive diffusion has led to not a few being sacrificed to promiscuous and haphazard probings.

I am, Sirs, yours faithfully,

C. S. JEAFFRESON,
Senior Surgeon to the Northumberland, Durham, and
Oct. 19th, 1889. Newcastle Infirmary for Diseases of the Eye.

ST. MUNGO'S COLLEGE, GLASGOW.

To the Editors of THE LANCET.

SIRS,—In your leading article of Oct. 12th regarding the foundation of this College, you say: "When the appointments to the new College had to be made there were clearly two ways of making them open to the governors: one by advertisement and public candidature and the selection of the fittest; the other by a committee of selection, whose choice should be submitted for ratification to the governors. The latter was chosen." That is correct so far. The latter method was *chosen* certainly, but it was not carried out; for, before any opportunity was given to the governors of ratifying the selections made, an official list of professors and lecturers was published in the *Glasgow Herald*. It is within the mark to say that to three-fourths of the governors this came as a complete surprise. One governor, accustomed to weigh his words, said frankly to me that he felt he had been made a fool of; while another layman, who has long occupied in the West of Scotland a first place in the administration of medical charities, told me that he had been compelled by this procedure to resign from the board—a resignation which, in the interests of St. Mungo's College, I am glad to understand has been withdrawn.

I am, Sirs, yours faithfully,

Glasgow, Oct. 14th, 1889. J. WALLACE ANDERSON.

"CURIOUS INQUEST REPORT."

To the Editors of THE LANCET.

SIRS,—In fairness to myself regarding the report in THE LANCET of Oct. 5th in reference to an inquest on the body of a child found in the Grand Junction Canal, I ought to state that the report in the *Kensington News* appears to have been somewhat inaccurate. The facts are these. The body when found was well-nourished and healthy-looking, and from all appearances seemed not to have been very long in the water, so much so that I performed artificial respiration for some considerable time. There were no marks of violence on the body, except that the right humerus was fractured. The string around the neck was very loose, leaving no mark.

At the post-mortem examination I was assisted by my friend Dr. Skinner, and we found that the signs of drowning were absolutely negative, as given by Guy and Ferrier's and Husband's books. There were no injuries to the head, but the brain was quite disorganised. On examining the fracture of the humerus, there was not the least ecchymosis around the injury. We concluded that there was no evidence of drowning, and considered that death had taken place before the body was placed in the water.

I am, Sirs, yours truly,

Harlesden, N.W., Oct. 11th, 1889. HENRY A. BABER.

NECROSIS OF THE ALVEOLAR PROCESSES.

To the Editors of THE LANCET.

SIRS,—In recording two interesting cases of necrosis of the alveolar processes following measles, in your issue of Oct. 5th, Mr. Lucas states that he has not known of any case of typhoid fever resulting in exfoliation of bone in this situation. It may be of interest to mention a case which occurred in my practice some few years ago, in which a boy, aged seven, recovering from typhoid fever, became the subject of acute necrosis of the alveolar process of the left superior maxilla. The disease was somewhat extensive, but the necrosed portion came away quite easily after a time, as a tooth was firmly fixed in it, and by seizing the latter with a pair of tooth-forceps the whole separated.

I am, Sirs, yours faithfully,

Portsmouth, Oct. 7th, 1889. J. G. BLACKMAN.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

Presentation and Farewell Dinner to Mr. Reginald Harrison.

THE farewell dinner to Mr. Reginald Harrison took place at the Adelphi Hotel on the 5th inst., amid surroundings of which any surgeon, metropolitan or provincial, might have been justly proud. The company numbered nearly 150, and comprised many friends from a distance. Among the lay guests were the Very Rev. Dr. Lefroy, Dean of Norwich; Mr. H. B. Gilmour, chairman of the Royal Infirmary; Professor Rendall, principal of University College; and Captain Nott-Bower, head constable of Liverpool. Mr. Mitchell Banks, senior surgeon to the Royal Infirmary, presided in a most felicitous manner, the toasts were few and well selected, and the musical arrangements were excellent, the company furnishing an amount of amateur talent sufficient to satisfy any audience however critical. In proposing the toast of "Our Guest," Mr. Banks gave a very interesting sketch of Mr. Harrison's career, which, with some additions, may be advantageously reproduced. It affords a very excellent example to all members of the profession of what may be done by energy and perseverance. He first studied at the Stafford General Hospital, where Mr. Moreton, of Tarvin, was then house surgeon, to whom he expressed himself as being much indebted. Subsequently he studied at St. Bartholomew's Hospital Medical College, and soon after obtaining his diplomas he came to Liverpool in 1859 as house surgeon to the Northern Hospital, not having, as he observed, the acquaintance of one professional friend in this city or neighbourhood. In 1860 he became resident surgeon to the Royal Infirmary, where he remained three years, and after a short absence he commenced practice here, becoming demonstrator of anatomy and registrar at the School of Medicine, and later on surgeon to the Northern Hospital. The School of Medicine was at that time in so languishing a state that it was seriously contemplated to close it altogether, and its resuscitation was work for which Mr. Harrison was thoroughly fitted. In 1868 he became assistant surgeon to the Royal Infirmary, full surgeon in 1874, and senior surgeon in January last on the retirement of Mr. Bickersteth. In 1880 he was elected president of the Liverpool Medical Institution, and in 1883 he delivered the address in Surgery at the annual meeting in Liverpool of the British Medical Association. Mr. Banks concluded an admirable speech by uncovering a handsome silver bowl and two goblets, which, with an album containing the names of all the subscribers, constitute the testimonial. These he formally presented to Mr. Harrison. The latter on rising received an ovation which it was evident he deeply felt. He expressed his gratitude in feeling terms, paid warm tributes to his old master, Mr. Moreton, his colleagues at the infirmary, and his numerous friends, all of whom he hoped often to see again. He has received the appointment of surgeon to St. Peter's Hospital in the place of Mr. Walter Coulson, and leaves Liverpool with the good wishes of all his professional brethren.

Death of Henry Lowndes, L.K.Q.C.P.I.

The circumstances attending the death of Mr. Henry Lowndes make it particularly sad, and its announcement was received with much regret by a wide circle of friends, much sympathy being felt for his widow and other relatives. He had not yet completed his sixty-second year, and up till very recently appeared to be in his usual good health. But he had been subject to varicose veins in his right leg; and one of these recently becoming ulcerated, he was advised to abstain from work for a time. Not wishing, however, to disappoint his patients, he continued to visit them until he became physically unable to do so, and when at last he took to his bed, it was evident to his medical attendants, Dr. Glynn and Mr. George Hamilton, that his case was a very serious one. In spite of all their efforts and of the most devoted nursing, he sank and expired shortly after noon on the 14th. He was educated at the Liverpool Royal Institution, receiving his medical education in Liverpool and Edinburgh. He was house apothecary at the Liverpool Royal Infirmary from 1851 to 1853, and then commenced private practice, becoming honorary surgeon to the South Dispensary, and later on junior surgeon and full surgeon to the Northern Hospital. This office he resigned in 1881, being elected consulting

Digitized by Google

surgeon, which office he held at the time of his death. He was always of a very modest, retiring disposition, preferring a quiet domestic life, and employing his leisure time in the study of medical and other literature. He was an accomplished linguist, and published a book of "Poems and Translations," as well as one on "Maintenance of Health." He also contributed many papers and cases to the medical periodicals. His funeral took place to-day, and was attended by a very large number of his medical friends.

Liverpool, Oct. 16th.

NORTHERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENT.)

Newcastle.

AT the late presentation of prizes to the evening classes in connexion with the Durham College of Science Professor Garnett spoke of the difficulty of students attending classes in the evening when they commenced work so early as six o'clock in the morning, and he urged the necessity of further rest for the young men, and thought it might be arranged, without loss to the employers, that apprentices should be allowed to lose a quarter in the morning when attending evening classes. Most people who consider the requirements of lads as to sleep will agree with Professor Garnett's suggestion as having a sound physiological basis, and it is to be hoped it may be acted on.—I hear that the affiliation project shadowed forth by Mr. Lawson Tait on his late visit to Newcastle, whereby the colleges at Birmingham might be connected with the University of Durham, in a similar manner as the Newcastle College of Medicine is at present, is now under the consideration of the authorities at Durham. Some doubts are expressed by outsiders as to the feasibility of the scheme; it must, however, be remembered that the doubters have no real knowledge of the full scheme or how the negotiations are proceeding at Durham.—As an instance of the increased interest now being taken by workmen in our medical charities, it may be mentioned that the *employés* of Sir W. G. Armstrong, Mitchell, and Co., at Elswick, have contributed the large sum of £377 for the quarter to the medical charities of this city. Of this the Royal Infirmary takes £243.—Although I cannot quote exact numbers at present, I hear that the entries of students at the Medical College and Royal Infirmary are very large this session.

Sunderland.

Some alarm was caused in Sunderland by the death of a man from the bite of a dog. Dr. Drinkwater, who attended the man and gave evidence, made the matter very clear. He said the man had three severe bites on his arm, and worse bites he had never seen, but that the man was at the same time suffering from heart disease and chronic disease of the liver and kidneys, and that it was owing to these maladies and the shock that he succumbed.

Horse Flesh.

It appears from late police evidence given at Carlisle and Rothbury that there is an extensive traffic in the flesh of old and diseased horses between the north of England and Antwerp. The inspector stated that no less than seventeen old and broken down horses were despatched from Carlisle to Antwerp in one week, where they would be cut up for beef or sausages. Some men were fined also at the Rothbury Police-court last Saturday for cruelty to old horses, driving them when lame and in great pain from the upper part of the county of Northumberland down to the vicinity of North Shields, to be ready for shipment to the Continent. It came out in evidence that a better price was obtained when they were delivered just alive—viz., 2*s.* per stone.

Ambulance Work in the North.

Considerable activity is just now evident in the north as to ambulance work. At Morpeth Dr. MacDowall of the County Asylum and Dr. Brumwell have offered to give instruction to the classes formed at the mechanics' institution. At Bedlington also large classes have been formed, and some have been inspected by Surgeon-Major Hutton.

Memorial to a Medical Assistant.

Within the last few days a very elaborately carved monument has been erected in Birtley cemetery, by a few friends there, as a memorial of the late Mr. Borland, who was for some years assistant to Dr. Wilson of Birtley, county Durham. The feeling is to be commended which commemorates the memory of a faithful assistant.

Newcastle-on-Tyne, Oct. 16th.

EDINBURGH.

(FROM OUR OWN CORRESPONDENT.)

The Opening of the Medical Classes.

IN connexion with the opening of the medical classes this year, it may be pointed out that many of the conditions of student life will be very considerably modified by the opening of the University Students' Union, by the alterations in the regulations for the appearance of candidates at the first professional examination, and by the new departure of granting special examinations on a regular system. Most of these subjects were referred to by one or other of the university professors or extra-mural lecturers in their opening addresses. It is announced, too, that the students have made arrangements to have a grand torchlight procession on the evening of the opening of the union. Referring to the new First Professional regulations, Professor Chiene said that it would be a question for future consideration whether there should not be a short course for junior students in the second summer session. By such a short course the great difficulty which constantly confronted him at the beginning and throughout the whole session—that he was dealing with two bodies of men—would undoubtedly be lessened; the gap between the junior and senior classes would be decreased, and their work, difficult as it was, would to a certain extent be lightened. Such an arrangement might with advantage be extended to other classes. Professor Chiene also referred to the apprentice system. He contended that the disappearance of the doctor's apprentice is by no means an unmixed good, and he dwelt with some fondness on the days when apprentice and dispensary work occupied a much more important position in medical education than they do in the present day. With the demands made by each professor on the time of the students for lectures, practical classes, clinical instruction, ward work, demonstrations, and post-graduate clinical instruction and infirmary residence, one wonders where and when the student is to get time for it all unless he pursues his studies for some such extended period as, say, a decade. If there is too little practical instruction at present there must be too much lecturing. That is the only way out of the difficulty. Professor Simpson took as the subject of his inaugural address, the question of the admission of women to the medical profession. Although he was by no means sanguine in regard to the employment of women in the medical profession in this country, he laid great stress on the fact that there was a very wide field in which they might work in India and elsewhere. Few of the other professors gave a special opening lecture, most of them contenting themselves with dealing with part of the work of the course.

Rearrangements in the Extra-mural School.

Since last session several rearrangements have been made in the lecturing staff in the Extra-mural Medical School. Dr. Craig has removed from Minto House to Surgeons' Hall, where he succeeds Dr. G. A. Gibson as lecturer on Materia Medica. Dr. Gibson now lectures on Practice of Physic at Minto House School of Medicine, and Dr. Ralph Stockman, late senior assistant in the Materia Medica department in the University, has succeeded Dr. Craig. All these gentlemen announced that they would deliver the first lectures of their courses to-day. Dr. Craig, in his opening address, speaking of the extra-academic Medical School, pointed out that it was founded by the Royal College of Surgeons, and that it had been in existence doing good work, for a period of 384 years, so that in sixteen years there would be a celebration of its 400th anniversary. Other changes in the school are the removal of Dr. Scott Lang to the old Dental Hospital and of Mr. Drinkwater to the adjoining buildings in Chambers-street. Most of the classes were crowded, and one wonders where all the students come from. The Anatomy students, however, are not settling down well, many of them appearing to be waiting to see whether Dr. Symington is to be appointed to the Aberdeen chair or not. Nothing has yet transpired as to the course that Lord Lothian will pursue in filling up the

Digitized by Google

vacancy, though the Aberdeen men are no doubt as anxious as the Edinburgh men are to have the post filled at once.

Funeral of the late Mrs. Gunning.

Many would hear with feelings of deep regret of the death of the lady whose remains were buried in the Grange Cemetery to-day. Dr. Gunning's name will be handed down in connexion with the numerous munificent prizes given to the University of Edinburgh and the Edinburgh Colleges. He has warm friends in both Scotland and England, many of whom were present at the funeral.

New Prizes in the Extra-mural School.

A valuable gold medal for Materia Medica and Therapeutics has been presented for competition to the Royal College of Surgeons by Colonel William Lorimer, Bathgate, in memory of his father, who was a lecturer on Materia Medica in the Surgeons' Hall. A second prize is one of £20, to be awarded to the best student in Chemistry at the Marshall-street School. It should have been mentioned that Dr. Matheson has commenced a course of lectures on Midwifery and Gynæcology in this school.

The Scottish Universities' Commission.

It appears to be an open secret that the Scottish Universities' Commission held a kind of preliminary meeting on Monday, when arrangements were made for the regular meetings, which are to commence in January next.

Edinburgh, Oct. 15th.

DUBLIN.

(FROM OUR OWN CORRESPONDENT.)

Death from Chloroform in the Richmond Hospital.

A WOMAN named Delaware, aged forty-seven years, died on the 12th inst. during the administration of chloroform. The deceased was suffering from disease of the bone of the left thumb, caused by an injury received about a month previously. An operation being considered advisable, she was brought into the operating theatre last Saturday morning, and, the heart having been examined, a little chloroform was administered prior to the use of ether. Before she was fully under the influence of chloroform dangerous symptoms occurred, and death supervened. A post-mortem examination showed that death took place from fatty degeneration of the heart, and the coroner's jury found a verdict in accordance with the medical evidence, and expressed the opinion that the chloroform had been skilfully and properly administered.

Royal College of Surgeons in Ireland.

Two members of Council have resigned—viz., Messrs. Corley and Kidd, the last named owing to an informality in reference to his election in June, while Mr. Corley retires in order to become eligible as a candidate for a professorship of surgery in the Amalgamated Schools. Mr. Kidd is a candidate for re-election, while Dr. Frazer and Messrs. Swanzy and Lentaigne also seek seats on the Council. The election for these two vacancies will take place on the 22nd inst. On Nov. 7th the Council will elect professors in the subjects of anatomy, physiology, and pathology, and Mr. Heuston, member of Council, will retire, as he seeks election to the chair of anatomy.

St. Vincent's Hospital, Dublin.

Considerable changes have recently taken place in the medical staff of this institution. Dr. McHugh succeeds Dr. Quinlan as visiting physician, and Dr. O'Carroll leaves the Richmond Hospital and becomes attached to St. Vincent's as physician to the extern department. Mr. Pattison will be surgeon for the extern department, and Drs. Moore and Thompson resident medical officers.

The Distribution of Enteric Fever in Dublin.

Enteric fever prevails rather extensively at present in Dublin, and some obeervations on the distribution of enteric fever in the city of Dublin, by Dr. Grimshaw and Sir Charles Cameron, published in an appendix to the latter gentleman's annual report for 1888, may not be out of place at this particular time. When it is remembered that enteric fever is generally considered to be dependent on defective drainage or impure water-supply, it is difficult to understand why for some years the disease has shown a tendency to increase, especially as the water is remarkably good, and the drainage has been steadily though slowly improving. Pettenkofer has shown that the geological condition favourable to the spread of cholera is also favourable to the prevalence of enteric fever, and cholera in 1866 prevailed to a much greater extent on the gravel beds than on the stiff clay, these formations constituting the ground on which Dublin and its suburbs are situated. For example, the deaths on the gravel beds were at the rate of 1 in 365 of the population, while off the gravel the rate was only 1 in 531. One reason why we might expect to find a greater prevalence of enteric fever in the gravel is afforded by the fact that it lies at a lower elevation than the clay, and in many places rises scarcely above high water in the river and its estuary. The gravels in Dublin are, in fact, waterlogged for a large portion of the twenty-four hours. As the gravel everywhere interposes between the clay and the river, the whole of the drainage of the latter, except that portion which enters the sewers, passes into the gravel.

Muzzling Dogs.

By a recent order dogs are prohibited, under a penalty, from going without a muzzle in the South Dublin district; but, strange to say, this rule does not apply to the north part of the city.

Dublin, Oct. 15th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The French Congress of Surgery.

THE fourth Congress of French Surgeons commenced its sittings last Monday in the large lecture theatre at the Paris School of Medicine. Although styled a French Congress, it partakes more perhaps of an international character, for several foreign surgeons of note were present, amongst whom may be mentioned Sir Thomas Longmore of Netley, Tilanus of Amsterdam, Thiriar of Brussels, Démosthène of Bucharest, Roux of Lausanne, Reverdin of Geneva, Bloch of Copenhagen, and others. Baron Larrey, the president, and the descendant of the famous Larrey, the military surgeon of the Napoleonic campaigns, opened the sitting in a neat address, in which he welcomed the foreign surgeons, and referred to the loss French military surgery sustained in the death of Legouest and Perrin. Then began the reading of papers. One of the most interesting of those read so far was that by M. Guyon on the "Immediate and Remote Results of Operations for Local Tubercular Disease," which gave rise to an animated and instructive discussion. M. Guyon gave the detailed record of three cases of tubercular disease of the bladder on which he had operated. One patient had suffered from vesical tubercular disease for two years previously to operation, which was undertaken in July, 1885. He made a good recovery and has had no recurrence. The second case, on which he operated in April, 1887, succumbed in July, 1889, two years after, to suppurating nephritis, a complication which M. Guyon says existed at the time of the operation. At the autopsy the left kidney was found to be completely destroyed, and the right was also deeply involved, but nowhere could the most minute search reveal a return of the tubercular growths. This, of course, was the interesting and important point, and M. Guyon had therefore good reason for believing that had it not been for the kidney lesion the scraping and the application of the actual cautery which the bladder underwent would have cured the patient. The explanation of these encouraging results was to be found in the fact that tubercular disease of the bladder had its origin very superficially. It has indeed been shown to begin in the mucous membrane, and to be there confined for some period, invading later on the deeper coats, so that a time comes when it must be pronounced inaccessible; but how to define this limit is not an easy matter. His third case was one he operated on in 1888 for vesical mischief dating back nine months. The kidneys here also were evidently diseased, yet, as the patient was in considerable pain and could get no repose, being compelled to micturate as often as 100 times in a night, M. Guyon resolved to try to relieve his sufferings. And in this he was successful, for the operation which he practised, a supra-pubic one,

Digitized by Google

greatly ameliorated the distressing symptoms, and although he could hardly hope to save one with kidney disease so advanced, still he lived in comparative comfort until carried off by his renal malady a year afterwards. Here, again, at the autopsy, M. Guyon was gratified to find that there was not the smallest trace of a return of the tubercular matter. In these cases he much preferred the supra-pubic operation, as undoubtedly the safer; but how to diagnose when the disease has obtained too great a hold for operation is by no means easy. The symptoms are dated so differently by patients that the fixing of the limit in this way is misleading. Of his three cases, one referred his symptoms back two years, the other two at eight and nine months respectively. Of the three, it will be observed that the only one cured was the first. M. Lavaux thought that in all these cases the kidneys would be found to be irreparably diseased, and that it was beyond our power to arrest the tubercular evolution; and inasmuch as one could alleviate the patient's sufferings by other means, such as by the injection of boricated solutions and cocaine, vesicotomy, with its attendant risks, was hardly justifiable. M. Guyon rejoined that he was not to be understood as being an indiscriminate advocate for a cutting operation. He admitted that one might in many cases relieve the patient by simpler methods, but when these failed, or were no longer beneficial, he would, rather than leave the patient to his sufferings, intervene, as he had done in the examples given. Seeing, too, how greatly the risks of operation were now reduced, and the encouragement to be gathered from the superficiality of the tubercular process in the early stages, he considered it almost his duty, in the interests of his patient, to go further. M. Verneuil did not take a very favourable view, surgically, of tubercular mischief in whatever part of the body it manifested itself. He did not remember to have seen many patients living ten years after they had undergone amputation for tubercular growth; although he allowed that when this disease invaded the upper extremity, it was much more susceptible of cure than when it appeared in the lower limbs. As to immediate results, one had, on the whole, the right to take an optimistic view; but it was otherwise should one take into account the fate in store for those operated upon. Before he was told of the "cure" of one of these cases, he would like to be informed what were precisely the lesions for which the operation was performed; what were the age, family history, and social status of the patient; what was the exact nature of the operation, and what was the treatment both before and after. M. Ollier, comparing the results of amputations with those of resections of the foot in the tuberculous, advocated amputation where there was any visceral lesion or where the patients were no longer young; but when conditions of age and constitution were favourable he preferred the conservative procedure. During the last four years he had resected the tarsus and ankle-joint thirty-two times, with only one death; and it was to be noted that in these operations on the lower limb the patient during convalescence was placed in a less favourable position than when it was a question of the upper extremity, owing to the longer time it was necessary to keep him indoors in the recumbent posture. As regards the remote results in these thirty-one cases, he admitted the time was too short to judge, but he had under observation other patients on whom he had operated five and six years ago, who were in excellent health and in whom he feared no return of the mischief. On the whole, therefore, he would counsel operative intervention in tubercular disease. M. Démosthène said that at the Hospital of Bucharest surgical tuberculosis furnished 15 per cent. of the cases. Of 429 tubercular admissions, he had operated on 281, with a mortality of 4·2 per cent. The immediate results therefore may be said to have fully justified operative interference. As to remote results, he was unable to speak positively, but he was, however of opinion that operation had put a great many of his cases beyond danger from ulterior tubercular trouble. It could not be pretended that surgical action was a specific for tuberculosis; the ideal would be rather to bring about a microbicidic action in the organism, but in the meanwhile, rather than rest with crossed arms, one ought to have recourse to those operations which, while not guaranteeing the future, yet gave results that could not be overlooked. M. Terrillon, speaking of tubercular disease of the genito-urinary organs, said he advised castration when the testicle was involved, and removal of the uterine appendages in cases of tubercular salpingo-ovaritis. He had performed this latter operation six times, with one death. He granted the difficulty of the operation owing to adhesions, as well as that of differential diagnosis, which could be made on general rules only. If, however, there was tubercular lung mischief, that seemed to him a further argument for the removal of the second and accessible focus of disease. The foregoing, in *résumé*, were the most important contributions to the discussion on this question. Another interesting item was the bringing before the Congress, by M. Roux of Lausanne, a patient on whom he had successfully performed the somewhat rare operation of resection of the iliac bone for osteo-sarcoma. Very considerable incisions had of course to be made to circumscribe the bone, and to separate it from its extensive muscular attachments, as well as from the ischium, the latter proceeding proving extremely laborious and difficult. The femur was divided obliquely near its head. Two months after this formidable operation the patient was able to be up and about. He is now quite recovered, and can walk in a sufficiently satisfactory manner. M. Roux was naturally much congratulated by the members of the Congress. M. Thiriar of Brussels next read the notes of a case of enormous fibro-lipoma of the fatty capsule of the kidney weighing no less than eleven kilogrammes, or about twenty-two pounds, for which he had operated. The patient was a female, aged sixty-three years, in whom the operator admitted he had diagnosed a multilocular cyst of the right ovary. The tumour showed itself in the left side first, and was said to have grown rapidly. The growth gave distinct signs of fluctuation, and was quite movable. Percussion was absolutely dull in the right, but resonant in the left, flank. The urine showed nothing abnormal. The operation was carried out under antiseptic precautions. There were no adhesions, but the right ureter and kidney were involved in the growth, and had to be ligatured and removed. The recovery was rapid and good. Three days after operation the urine passed amounted to 1300 grammes, and within a fortnight the patient went out perfectly cured.

Professional Services are Obligatory.

It will be recollected I gave in your columns recently an account of the dispute that has arisen between the medical practitioners of Rodez and the local authorities, in which the former, acting, as they thought, on their rights, declined giving their services to the authorities of the place in a certain emergency. For this the procureur-général of Montpellier sought to incriminate them under a certain article of the Penal Code, and issued summonses against them to appear to the charge at the local court. The medical men, it will be remembered, who were ably defended, stoutly maintained they were not bound to respond, and that, being private and therefore perfectly free practitioners of their profession, they could give or decline to give, as might to them seem fit, their professional services. The judgment, which was then postponed, has now been rendered, and it will surprise not a few who practise physic to learn that the gist of it is that here they are bound to give in good faith their professional services when solicited by those who represent the law. I gave at the time the precise wording of the article under which the medical men of Rodez were charged. The magistrate, in giving his decision, ruled that they were guilty of a contravention of the said article under the phrase *flagrant délit* which occurs in it, and therefore he fined them individually six francs, and collectively the costs of the process. The medical practitioners, I hear, are determined to carry the matter to the Court of Cassation—that is, the parallel in France of your legal House of Lords.

Paris, Oct. 15th.

(FROM OUR OWN CORRESPONDENT.)

Inoculation against Inflammation of the Lungs in Cattle.

AT the end of last year the Prussian Minister of Agriculture ordered experiments to be made on cattle, in order to decide the extremely important question whether inoculation affords protection against infectious inflammation of the lungs in cattle or not. These experiments were carried out under the superintendence of Professor Schütz and the departmental veterinary surgeon Steffen, in the Government district of Magdeburg, and have recently been finished.

Digitized by Google

On Oct. 8th last twelve young bulls were inoculated with fluid and particles from diseased lungs; three with warm and three with cold fluid; three with warm and three with cold particles. Those inoculated with warm fluid contracted the disease most severely. On Oct. 26th all twelve, along with four uninoculated animals of the same age and breed, were placed among cattle suffering from infectious inflammation of the lungs, and their noses were repeatedly brought into the closest contact with those of the diseased animals for hours together. In December and in January all the animals were killed, and the post-mortem showed that the twelve inoculated animals had remained healthy, and that three of the four uninoculated ones had contracted the disease. The experiments were now repeated, special care being taken that all the animals (inoculated and uninoculated) were exposed to as nearly as possible equal degrees of infection, and that the fluid used for inoculation was taken warm from the lungs which had proved most effective. On Nov. 9th twelve young bulls were inoculated with different quantities (0·05 to 1·0 cubic centimetre) of warm lymph. The quantity of the fluid used did not affect the intensity of the local process. One bull died on the thirty-fifth day after inoculation of peritonitis, caused by the spread of the inoculation process. On Dec. 1st the inoculated bulls were placed among bulls suffering from infectious inflammation of the lungs, but did not contract the disease. On Jan. 27th they were taken to another stall, and again placed among bulls suffering from the disease in question. On April 12th the eleven inoculated and two uninoculated bulls were inoculated with warm lymph between the neck and the breast, after which the two latter became severely ill, and one of them died. The previously inoculated animals, on the other hand, showed only slight symptoms at the place of inoculation. On April 12th twenty grammes of warm lymph were mixed with 2000 of warm sterilised flesh broth and sprayed before the nostrils of the inoculated animals. They remained healthy. On May 13th they were again placed among others which were suffering severely from the disease in question. After this no morbid symptoms were observed in them. On June 26th one cubic centimetre of warm lymph was injected into the lungs of each of the inoculated and of two uninoculated bulls. The inoculated animals remained healthy, while the two uninoculated ones contracted the disease in a very severe form, and one of them died. At the end of July the inoculated animals were killed and dissected, and no abnormal developments were found. It therefore now seems to be proved that cattle inoculated with fresh warm lymph are protected against infectious inflammation of the lungs.

Daggeian Fever.

Some days ago the *Kreuz Zeitung*, one of the leading Berlin dailies, published the following communication, received from Athens, dated Sept. 26th:—"For a week past news have come daily from the Piræus to the effect that 'daggeian fever' (*Δάγγειος πυρετός*) has broken out there, but the statement has been persistently denied by the medical and governmental authorities. Yesterday, however, Alexandrogiannis, municipal sanitary councillor in the Piræus, in agreement with the physician Politakis, proved to the mayor in a report of some length that 'daggeian fever' is raging in the Piræus. The first cases were observed three weeks ago, and, as far as has yet been determined, more than a hundred persons have already been seized by the fever, the character of which, however, has proved in all cases to be benign. This fever, which is very frequent in Egypt and Syria, broke out with great violence in Smyrna two months ago, and about 4000 persons are said to have been seized by it there. Within the last few weeks, too, it has been spreading in Constantinople, for which reason the Greek Government forbade the import of clothes and clothing stuffs from Turkey till further notice. Despite this prohibition, however, it has spread to the Piræus. It is rarely fatal, but spreads very rapidly. The first symptoms are intense redness of face, neck, and hands, frequently accompanied by an eruption. The patient then feels violent headache, darting pains in the eyes, and humming in the ears; he cannot work, shuns the light, and sleep cannot be obtained. Gradually other parts of the body are attacked, till the disease settles with special vehemence in the legs, especially in the knees. The crisis comes within three to eight days, after which, with good medical treatment, the patient recovers in four or five days, but generally remains weak for two or three weeks longer. Comprehensive measures are now to be taken by the Government to prevent the further spread of the disease, but in prospect of the approaching festivities, the general anxiety is great." This communication induced Dr. Friedrich Hirtl to write the following remarks to the *Norddeutsche Zeitung*: "The *Kreuz Zeitung* hears from Athens that the 'daggeian fever' has broken out in the Piræus. I am myself by no means an authority on fevers, but suffered about thirteen years ago in Southern China from a disease which the English doctors called 'dengue fever' and the German doctors 'Dengelfieber.' To judge from the symptoms, 'daggeian fever' is identical with that disease. It is less dangerous than painful; it is said, too, to be rapidly and widely contagious, as a case mentioned by Sale in his 'Anglo-Indian Glossary' shows, according to whom the father of an officer who suffered from this fever in the Bermudas was seized by the same disease in England three days after receiving a letter from his son, without, however, the fever spreading further. The name 'dengue' or 'dengy' is said to have come from the West Indies, where the negroes called it 'dandy fever,' owing to the stiff attitude to which it temporarily condemned the patient, which name was brought to Europe by Spaniards, modified into 'dengy.' An epidemic of this disease is stated to have raged on the Coromandel coast in 1780, and in Calcutta, Berampore, and other places in India in 1824, 1853, 1868–69, and 1871–72. On the last-mentioned occasion 70 per cent. of the European and native railway officials in Calcutta are said to have been seized by it. It seems that the disease has spread in the Mediterranean countries from Egypt." The *Frankfurter Zeitung* also prints a letter from Smyrna, dated Sept. 23rd, stating that an epidemic was raging, which, though not dangerous to life, had spread to a quite extraordinary extent, and in that city of 200,000 souls had attacked more than one-half of the population. It was called "deng," began with a shooting megrim, pains in all the limbs, and fever rising to 40° centigrade, and left great weakness, which lasted for a week or a fortnight. It was said to be endemic in Egypt, and not unknown in Spain. It might easily make the tour of Europe, unless winter sets in early to prevent it. The doctors had not yet found out how to deal with it; quinine had no effect on it. For fear of quarantine annoyances people made a home secret of it as much as possible. It nevertheless deserved attention and investigation. It had thrown many disagreeable hindrances in the way of the export business, which was usually very brisk at this season; many offices were closed because all the clerks were ill, and trade was at a standstill.

The Holiday Colony Fête.

The fête given to the poor city children who have been sent to the mountains and forests and shores this summer by the Holiday Colony Society was a great success. The Empress Frederick and her daughters, the Princesses Victoria, Sophie, and Margaret, were present, and were accorded an enthusiastic reception from young and old. Her Majesty expressed the satisfaction she felt at the great and rapid development which the utilisation of the summer holidays for the benefit of the health of poor city children had taken in Germany, and especially in Berlin.

The German Anatomical Society.

The German Anatomical Society, which was founded in 1886, will meet in the Anatomical Institute here on the 10th inst. Its leading spirits are Professor Kölliker of Würzburg, Gegenbaur of Heidelberg, His of Leipsic, Waldeyer of Berlin, and Bardeleben of Jena.

The Imperial Pharmacopœia Commission will meet here on the 11th inst., to discuss the new third edition of the Pharmacopœia, which, it is hoped, will be published next year.

An excellent drawing by Albrecht Dürer was found lately in a medical book in a library at Zwickau. It represents a dying man sitting behind a stove and Death threatening to extinguish the light of life, while a female form personifying the Art of Healing approaches to save.

Berlin, Oct. 8th.

KINGS'S COLLEGE, LONDON.—The Clothworkers' Science Exhibitions of £100 and £50 have been awarded to S. H. Ellis and F. C. Sprawson, and the Sambrooke Science Exhibitions of £60 and £40 to A. Bousfield and W. R. Bryett.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AT a quarterly meeting of the Council of the College, held on the 17th inst., the minutes of the ordinary Council of Aug. 1st were read and confirmed. It was agreed, on the recommendation of the Library Committee, that the library be opened on each week-day from the 21st inst. to Dec. 31st next, between the hours of 11 A.M. and 9 P.M., except on Saturdays, when it will close as usual at 1 P.M. It was also agreed, on the recommendation of the same committee, that Professor Muybridge's work on Animal Locomotion be purchased for the sum of £105, including the cost of mounting and binding. The other parts of the report from this committee were approved and confirmed.

The fifteenth report, dated Oct. 11th, of the Committee on the Extension of the College Premises, was read, adopted, and entered on the minutes. The Committee, having obtained the advice of Mr. E. Brace Hall, Chief Officer of the London Salvage Corps, and Mr. Salter, the architect, as to the additional fire apparatus required throughout the College buildings and for the protection of the two new museums, recommend the Council to sanction an expenditure for carrying out the suggestions made by Mr. Brace Hall and Mr. Salter, in accordance with estimates supplied by Messrs. Shand and Mason and Messrs. Higgs and Hill, that of the former amounting to £421, that of the latter to £140. With regard to the New Small Museum, the Committee recommend the Council to sanction an additional expenditure of £7 8s. for arranging the heating apparatus in a more satisfactory way than that originally proposed, and to accept the estimate of £757 by Messrs. Sage and Co. for supplying the wall-cases on the ground floor and first-floor gallery.

The report of the Committee of Management, dated Oct. 7th, was received and adopted. The Council, in pursuance of this, proceeded to the election of a member of that committee, in the vacancy occasioned by the President's retirement, he being eligible for re-election. Mr. Jonathan Hutchinson was elected to the vacancy.

The Council then proceeded to the election of the four Examiners in Public Health nominated by the Committee, and Drs. Stevenson, Ballard, Thorne Thorne, and Corfield were re-elected.

It was referred to the legal advisers of the College to advise the Council on the important question whether the General Medical Council has the power legally to impose on the licensing bodies the conditions on which diplomas in public health are to be granted by them.

The Council approved of the unanimous recommendation of the Committee of Management that the period of professional study should be extended from four to five years, and it was referred to the Committee to consider and report to the two Colleges on the best mode of giving effect to such recommendation.

Mr. John Langton, member of the Court of Examiners in Surgery, and Mr. Morton Smale were elected as members of the Dental Board.

The Council then proceeded to the consideration of the draft of the report to be presented to the Fellows and Members of the College at the meeting appointed to be held on Thursday, Nov. 7th. The report was adopted, and will be presently circulated.

It was agreed, on the motion of Mr. Heath, that it be referred to the Nomination Committee to consider and report to the Council on all vacancies occurring from time to time in the Court of Examiners.

Obituary.

DR. ADOLF FERDINAND DUFLOS.

THIS eminent pharmacist died on the 9th inst. at Annaberg, in Saxony, in his eighty-eighth year. He was born on Feb. 2nd, 1802, at Artenay, near Orleans, where he lost his parents when quite a boy. His uncle, who was a military surgeon in the service of France, brought him with his regiment to Germany and placed him as a pupil in the house of the Rector of the Torgau Lyceum. The boy, having shown a decided talent for chemistry, particularly in its medical aspects, was apprenticed to a professor of pharmacy in Annaberg, and thence, after a six years' probation, he proceeded to Breslau, where he continued to perfect himself in the subject at the famous Olearius Institute for eight years more. Thereafter he was appointed to the post of assistant lecturer in pharmacy in the University of Halle, and gave much satisfaction to his pupils during the three years he held the chair. Having returned to Breslau, he founded there, in conjunction with the eminent apothecary Langsch, a *fabrique* for pharmaceutical preparations, and at the same time inaugurated a course of lectures on Pharmacy as the Handmaid of Medicine. He published also many valuable works on his special subject, and their scientific value, high professional tone, and unusual literary merit induced the Breslau University to bestow on him, *honoris causâ*, its degree of Doctor in Philosophy. In 1842 he became Professor of Materia Medica in that seat of learning, having specially qualified himself by graduation for the post; and during a quarter of a century he drew around him an increasing number of pupils, attracted by his luminous exposition, his neatness and skill in experiment, and the charm with which he invested his subject. Advancing years and the consciousness of failing power led to his retirement in 1866, and till the day of his death he resided at Annaberg, the scene of his earliest studies, retaining to the last an active interest in the science and the profession in which, for so many years, he was an acknowledged master.

DR. PIETRO LAURA.

THIS able and versatile physician has just died at Genoa, after a life of steady medical work and public philanthropy. Like most of his septuagenarian contemporaries, his early studies were broken by the revolutionary upheaval of 1848—a movement in which he took part as "medical volunteer" in the ranks of "Young Italy." He served honourably not only as a surgeon, but as a combatant in the struggle against Austria, which closed so disastrously for his country at Novara, till renewed ten years later, and with victorious results, by the sub-Alpine statesman, Cavour. Having so distinguished himself in the campaign of 1849 as to earn the rank of staff-surgeon, he resumed his medical studies on the declaration of peace, and with other young Italians sought a home in the Argentine Republic, where he soon rose to be Director-in-Chief of the Civil and Military Hospital of Goaleguaychù. Another post he held concurrently with this was that of First Physician to the President of the Argentine Republic, Señor Urquina, whose brilliant achievements included the expulsion from Buenos Ayres of the absolutist adventurer, Rosas.

Dr. Laura exerted himself assiduously to promote the welfare of his countrymen in South America, and contributed to make the Argentine Republic the attractive resort it has long been for the Italian emigrant. He founded the first newspaper—a journal of moderate and enlightened views—ever published there in the language of Italy. Of late years he had come to reside permanently in his native land, and continued to earn the gratitude of his compatriots as a practitioner among the poor till death overtook him in the scene of his honourable labours.

Medical News.

EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGES OF PHYSICIANS AND SURGEONS.—The following gentlemen passed the Second Examination of the Board in Anatomy and Physiology at a meeting of the Examiners on the 10th inst.:—

W. A. Perry, student of University College; H. N. C. Atkinson, E. C. Adams and J. L. A. Hope, of St. Bartholomew's Hospital; W. E. de Korte, of Guy's Hospital; J. B. H. Dawson, of St. Mary's Hospital; W. B. Stanford, of Middlesex Hospital; W. H. A. Tebbs, of Westminster Hospital.

Anatomy only.—E. H. Smith, J. Kyffin, and C. E. Dawes, of London Hospital; J. R. Richmond, of King's College and Mr. Cooke's School of Anatomy and Physiology; J. H. Crawshaw and W. H. J. Huthwaite, of University College; W. P. Q. Daly and L. W. Bathurst, of St. Bartholomew's Hospital; R. S. Whitford, of Charing-cross Hospital and Mr. Cooke's School of Anatomy and Physiology.

Physiology only.—T. Stevens, H. D. Senior, H. Gardner, and J. H. Whitehead, of Charing-cross Hospital; D. L. Thomas, F. G. Scott, F. W. Walters, W. R. Mathews, F. J. A. Baldwin, and G. A. Simpson, of London Hospital; R. J. Rastrick and C. H. Willis, of

Digitized by Google

St. Bartholomew's Hospital; T. W. Smith and J. B. O. Richards, of King's College; W. J. Covey, of University College; H. W. Ramsay, of St. Mary's Hospital and Mr. Cooke's School of Anatomy and Physiology; W. A. Hayes, of Trinity College, Dublin, and University College.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen, having passed the necessary examinations, were at the ordinary meeting of the Council on the 1st inst. admitted Members of the College:—

Birkenhead, Harold, L.R.C.P.Lond., Witherby Rectory, Atherstone.
Borrett, George Goss, L.R.C.P.Lond., Philpot-street, E.
Jamieson, Sydney, L.R.C.P. Lond., Melbourne-place, Edinburgh.
Kempthorne, Albert Edwd., L.S.A., Oakley Neath, Glamorgan.
Lewers, Alex., L.R.C.P. Lond., Delamere-crescent, W.
McGowan, Jas. Sinclair, M.B. Victoria Univ., King-st., Oldham.

The following members, having previously passed the necessary Examinations, and having attained the legal age (twenty-five years), were at the same meeting admitted Fellows of the College:—

Dean, Henry P., L.S.A., University College Hospital; diploma dated June 9th, 1887.
Ward, A. H., L.R.C.P.Lond., St. Geo.'s Hospital; Nov. 10th, 1887.

ROYAL UNIVERSITY OF IRELAND.—The following candidates have passed the First Examination in Medicine of this University:—

Upper Pass Division.—Chas. Birmingham, Joseph Boyd, John Burns, William Chancellor, Edmond Kelleher, Purcell Lalor, Wm. McMath, Daniel O'Connor, Michael O'Reilly, John Wallace.
Passed.—Patrick Brady, John Brownless, William Canning, Thomas F. Chambers, John Dunne, Thomas Fennelly, Joseph W. Furey, George Griffiths, Amelia Grogan, James Lawther, John Longford, Florence McCarthy, Patrick McCarthy, Daniel Magee, Samuel Magowan, Jas. Mortell, John Patrick, John H. Thompson, Francis Whitaker.

The following candidates passed the Second Examination:—

Upper Pass Division.—*Alexander Blaney, *Robert Campbell, *Thos. Howard, James Lynass, *Daniel O'Callaghan, Daniel O'Driscoll, Patrick O'Sullivan, R. Torney.

* These may present themselves for the further examination for honours.

Passed.—James Auglim, Thomas Atkinson, Robert Beatty, Patrick Bennett, Michael Boyle, Richard Crosbie, Charles H. Foley, William Gordon, James Graham, William Hamilton, Benjamin H. Hosford, Patrick McGann, Adam Moss, Thomas Murphy, Patrick J. O'Brien, Michael O'Sullivan, David J. Ryan, James A. Scott, and Thomas H. Scott.

ROYAL VICTORIA HOSPITAL, BOURNEMOUTH.—An intimation has been received by the Committee of this hospital that the Prince of Wales has consented to open this hospital on Jan. 16th next.

THE PERSIAN GULF.—The British representative at Lisbon telegraphed under date of Oct. 9th as follows:—"Ports in Persian Gulf declared free from plague, but suspected of cholera."

DEVONSHIRE HOSPITAL AND BUXTON BATH CHARITY.—An anonymous benefactor has forwarded, through Dr. Robertson, a donation of £50 towards the funds of this hospital.

SERIOUS FOOTBALL CASUALTY.—A young man named Kingston, during a Rugby football match played at Rochdale on Saturday last, between Rochdale Albion and Milnrow Clubs, had his leg broken, besides sustaining internal injuries.

VACCINATION.—Mr. E. Climson Greenwood, L.R.C.P., M.R.C.S., has been appointed by the Privy Council Teacher of Vaccination at the Welbeck-street and Omega-place, St. John's-wood, stations, vice W. A. Limmer, deceased.

NINETEENTH CENTURY ART SOCIETY.—Saturday, the 26th inst., has been appointed for the private view of the Autumn Exhibition (the nineteenth) of the above Society, at the Conduit-street Galleries, and the Exhibition will open to the public on Monday, the 28th inst.

SOCIETY FOR RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN.—The quarterly court of the directors of the Society was held on Wednesday, Oct. 9th, at the house of the president, Sir James Paget, the necessary alterations in the new premises of the Royal Medical Chirurgical Society in Hanover-square not being sufficiently advanced to allow of the meeting there. Eight new members were elected, the deaths of three announced, and the resignation of one reported. Applications for grants were read from sixty-one widows, fourteen orphans, and three orphans on the Copeland Fund; and it was resolved that £1360 be distributed among them at the next court. The expenses of the quarter were £59 18*s.* 6*d.*

MEDICAL MAGISTRATE.—Dr. Macpherson Lawrie, of Greenhill, Weymouth, has been appointed by the Lord Lieutenant a magistrate for the county of Dorset.

WESTMINSTER HOSPITAL MEDICAL SCHOOL.—Entrance Scholarships have been awarded to Mr. E. G. Richards (£60), Mr. A. E. Jerman (£60), and Mr. M. Farrant (£60).

SOCIETY OF MEDICAL OFFICERS OF HEALTH.—At the annual meeting of the Society of Medical Officers of Health, held at the Holborn Restaurant, London, on the 11th inst., Mr. Henry E. Armstrong, medical officer of health for Newcastle-upon-Tyne and the River Tyne Port, was elected president for the ensuing year.

RABIES.—The number of dogs in England officially reported during the week ending Oct. 5th as afflicted with rabies was eight, against a similar number in the previous week. All the eight were killed. The distribution was as follows:—York (West Riding), four; and London, Northampton, Essex, and Kent, one each.

SUICIDE OF AN ARMY SURGEON.—On Monday Mr. H. K. Fuller, M.B., M.R.C.S., an army surgeon, threw himself in front of the up Salisbury train as it was approaching Wimborne Station. The front guard of the engine struck him, and the blow broke his neck. Deceased was thirty-two years of age, and was under treatment for mental infirmity.

A LECTURE ON HYDROPHOBIA.—Sir Henry Roscoe will take the chair at a meeting of the Balloon Society to hear a lecture by Mr. Frank Kerslake on the Cause and Prevention of Hydrophobia, in St. James's Hall (Regent-street entrance) on Thursday, Oct. 24th, at eight precisely. A resolution in support of Sir Henry Roscoe's Bill will be proposed by Dr. Fleming, C.B., President of the Royal Veterinary College. Mr. Victor Horsley is expected to speak. Tickets for reserved seats may be had by application to Mr. Kerslake, 12, St. George's-square, Primrose-hill, N.W.

THE GLASGOW SOUTHERN MEDICAL SOCIETY.—At the annual business meeting held in their rooms on the 10th inst., the following office-bearers were appointed: President, Robert Pollock, M.B.; vice-president, James Erskine, M.A., M.B.; treasurer, James Hamilton, M.B.; secretary, Alexander Miller, L.R.C.P. Ed.; editorial secretary, John Brown, M.B.; seal-keeper, R. A. D. Robb, M.B.; court medical, Drs. Glaister, Morton, Macmillan, Gilmour, and Rankin; extra members to complete council, Drs. Tindal, Barras, and McPherson.

THE HAMPSTEAD DEADHOUSE.—Attention was again called by the jury, at an inquest held at Hampstead on Monday, to the pressing need of a suitable mortuary for the parish, for the reception of the dead. The building at present used for this purpose is a dilapidated shed, absolutely without the necessary conveniences and accommodation for a proper examination of a dead body. The jury added a rider to their verdict, requesting the Local Authority to provide so necessary a sanitary requirement for the parish.

THE REGISTRATION OF PLUMBERS.—At a public meeting recently held in Edinburgh for the purpose of promoting the registration scheme initiated by the Plumbers' Company, the secretary of the Edinburgh District Council presented his report, from which it appeared that 145 plumbers had been registered, and that the council was in a good financial position. Dr. Littlejohn, city officer of health, said he was glad to find a trade asserting itself in the way the plumbers were doing. The clerk of the Plumbers' Company stated that over 5000 plumbers had been enrolled on the company's register.

BOSTON HOSPITAL.—The eighteenth annual report of this hospital, founded for Boston and the neighbouring parishes, shows that during the twelve months ending June 30th, 1889, the number of in-patients was 175, and 123 visits were paid to patients at their own homes. The receipts for the year were £734 9*s.*, and the expenditure £735 15*s.* 11*d.*, leaving a deficit of £1 6*s.* 11*d.*, in addition to which there still remains a deficiency of £196 8*s.* 11*d.* on the building fund, despite the fact that the debt was reduced by about £200 during the year. The committee earnestly appeal for donations to clear this sum off.

Digitized by Google

THE VACCINATION COMMISSION.—On Wednesday another sitting of the Royal Commission on Vaccination was held at Richmond-terrace. Lord Herschell (the chairman) presided. Dr. W. Gayton, of the Fever Hospital, Hampstead, and Dr. F. W. Barry, of the Fever Hospital, Sheffield, were examined.

PRESENTATION.—A very handsome tea and coffee service has been presented to Dr. Prance, on his retirement from practice, by his patients and friends, as a testimony of their esteem and regard. Several patients have also given valuable presents. Dr. Prance, on resigning the appointment of honorary surgeon to the Sailors' Orphan School and Home after thirty-three years' service, was accorded a cordial vote of thanks by the committee of management, and his services retained as a member of the committee.

SHEFFIELD PHARMACEUTICAL SOCIETY. — The sessional inauguration of the Sheffield School of Pharmacy took place on the 10th inst., the proceedings being of the usual annual character. In the evening there was a large gathering of students, friends, and local chemists in the large room of the Whiteley's Institute, which is rented by the Society. Mr. Atkins (Vice-President of the Pharmaceutical Society of the United Kingdom), in his address to the students, pointed out the strides made in pharmaceutical education in recent years, and expressed his strong conviction that a prolonged enforced curriculum was still indispensable for students. The future of pharmacy was a matter of anxiety and speculation, but, for his own part, he thought that a process of natural selection would prevail; chemists and druggists would dissolve partnership, the chemist to practise pharmacy with a higher recognised status than he now enjoys, the druggist with a lower qualification, and, it might be, a limited licence, supplying more as a drysalter the varied requirements of the community. Subsequently the annual dinner of the Society was held in the Masonic Hall.

BESTOWAL OF THE CROSS OF THE LEGION OF HONOUR ON A NURSE.—An interesting presentation has recently taken place at Tonkin, where the Governor-General conferred on the Superior of the Sisters of Mercy the Cross of the Legion of Honour, in the presence of the troops. The Governor addressed the recipient in the following terms:—"Sister Maria Theresa, you were only twenty years of age when you first gave your services to the wounded at Balaklava, and were wounded in the execution of your duty; you were again wounded at Magenta. You bravely nursed the wounded through all our wars in Syria, China, and Mexico. You were carried off the field at Wörth, and before you had recovered from your injuries you were again performing your duties. When a grenade fell into your ambulance you, without hesitation, took it up in your hands and carried it to a distance of 100 yards from the ambulance, when it exploded, wounding you severely. No soldier has ever performed his duty more heroically than you have done, or lived more successfully for his comrades and his country. I have the honour to present you, in the name of France and the French army, with the cross, which is only conferred upon those who have shown remarkable bravery in action. Soldiers, present arms!"

METROPOLITAN ASYLUMS BOARD.

Return of Patients remaining in the several Fever Hospitals of the Board at midnight on October 15th, 1889.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.*

BRACKENBURY, HENRY B., M.R.C.S., L.R.C.P., has been appointed Resident Medical Officer to the Hospital for Diseases of the Throat, Golden-square, W.

BRODIE, CHAS. GORDON, F.R.C.S., has been appointed Honorary Surgeon to the Western General Dispensary, Marylebone-road, N.W.

CAHILL, JOHN, F.R.C.S., has been appointed Surgeon to St. John's and St. Elizabeth's Hospital, Great Ormond-street.

CRUMP, THOMAS GREENWOOD, B.A.(Cantab.) M.R.C.S., L.R.C.P., has been appointed Assistant House Surgeon to the General Hospital, Birmingham, vice J. P. A. Walker, M.B., resigned.

DOUGHTY, D. S., M.B., M.S.Edin., has been appointed Medical Officer of the Ireby District, Wigton Union.

EDWARDS, F. SWINFORD, F.R.C.S., has been appointed Surgeon to St. Peter's Hospital, Covent-garden, W.C., vice Coulson, F.R.C.S., deceased.

FENWICK, E. HURRY. F.R.C.S., has been appointed Surgeon to St. Peter's Hospital, Covent-garden, W.C., vice W. Coulson, F.R.C.S., deceased.

HARRISON, REGINALD, F.R.C.S., has been appointed Surgeon to St. Peter's Hospital, Covent-garden, W.C., vice W. Coulson, F.R.C.S., deceased.

HARTILL, JOHN T., L.R.C.P. Lond., M.R.C.S., has been re-appointed Medical Officer, Willenhall and part of Wednesfield, Wolverhampton Union.

HUBAND, A. E., L.R.C.P., L.R.C.S., Medical Officer and Public Vaccinator, Sutton District of the Loughborough Union, has been appointed Medical Officer to the Sutton Bonnington Amalgamated Friendly Societies, vice F. J. Hindle, resigned.

HUTTON, JAMES ALFRED, M.R.C.S., L.R.C.P., has been appointed Assistant Demonstrator of Anatomy at the University of Durham College of Medicine, Newcastle-on-Tyne.

MCNAIR, GEORGE, L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer of the Deddington No. 1 District of the Woodstock Union, vice Edward W. Turner, deceased.

MILLIGAN, WILLIAM, M.B., C.M., has been appointed Assistant Surgeon to the Manchester Ear Institution.

PHILLIPS, JOHN, M.B., C.M., L.R.C.P.E., L.R.C.S.E., L.F.P.S.G., has been appointed Resident Physician to the North London Hospital for Consumption, Hampstead, vice R. A. Bindley, M.R.C.S., L.S.A., resigned.

PRAGER, J. F., L.D.S., has been appointed Dental Surgeon to the Western General Dispensary, Marylebone-road, N.W.

RAWES, WM., M.B., F.R.C.S., has been appointed Assistant in the Physiological Laboratory of the London Hospital Medical College, vice E. Hurry Fenwick, F.R.C.S., resigned.

RAWLINGS, HORATIO E., L.K.Q.C.P.Irel., M.R.C.S., has been appointed Resident Medical Officer to the Swansea Hospital, vice Dr. Kerr.

STEIN, C. G., M.R.C.S., has been re-appointed Medical Officer of Mansfield-Woodhouse.

THORBURN, WILLIAM, B.S. Lond., F.R.C.S., has been appointed Honorary Assistant Surgeon to the Manchester Royal Infirmary, vice F. A. Southam, F.R.C.S.. who has been appointed Honorary Surgeon.

TURNER, EDWIN, M.R.C.S., L.S.A., has been re-appointed Medical Officer, Stourbridge Rural District.

WINFIELD, ROLL G., L.R.C.P.Lond., M.R.C.S., has been appointed House Surgeon, Leicester Infirmary.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement.

BRADFORD INFIRMARY AND DISPENSARY.—House Physician. Salary £100 per annum with board.

BURTON-ON-TRENT INFIRMARY. — House Surgeon. Salary £130 per annum with a prospect of increase, and rooms in the infirmary free, also coals and gas.

CHARING-CROSS HOSPITAL, London.—Surgical Registrar, for one year, at a salary of £40, but the holder is eligible for re-election.

FLINTSHIRE DISPENSARY, Bagillt-street, Holywell.—House Surgeon. Salary £100 per annum, with furnished house, rent and taxes free, with a prospect of £20 increase after twelve months; also coal, light, water, and cleaning, or in lieu thereof the sum of £20 per annum.

GENERAL HOSPITAL, Birmingham.—Assistant Physician, for three years. Honorarium £100 per annum.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, London, W.C.—Resident Medical Officer as House Surgeon, for one year. Salary £50 per annum, with board and residence in the hospital.

LIVERPOOL DISPENSARY, 34, Moorfields, Liverpool.—Two Assistant Surgeons. Salary £80 per annum each, together with apartments, board, and attendance.

LIVERPOOL EYE AND EAR INFIRMARY.—House Surgeon. Salary £80, with maintenance in the house.

LIVERPOOL ROYAL INFIRMARY.—Honorary Surgeon.

NORTH RIDING INFIRMARY, Middlesborough-on-Tees.—House Surgeon.

NORTH-WEST LONDON HOSPITAL, Kentish-town-road.—Senior Resident Medical Officer. In the event of the Assistant Medical Officer being appointed to the senior post, candidates should state if they will take the Junior appointment. Also Two Clinical Assistants, Department for Diseases of the Skin

Digitized by Google

PARISH OF THE UNITED PARISHES OF WHITTLESEY.—District Medical Officer and Public Vaccinator. The Medical District comprises the northern portion of the parish; the Vaccination District comprises the outlying portion of the parish. The salary as District Medical Officer will be £70 per annum, with the usual extra medical fees for midwifery and surgical cases. The fees for vaccination and revaccination will respectively be 3s. and 2s. per case.

PARISH OF EDAY, Orkney, to Inspector of Poor.—Resident Medical Officer. Salary £70 a year and practice.

SALOP INFIRMARY, Shrewsbury.—House Surgeon. Salary £100 per annum, with board and residence.

ST. MARY'S HOSPITAL, Quay-street, Manchester.—House Surgeon and Resident Obstetric Assistant Surgeon. Salary £120 per annum, with board and residence.

THE COUNTIES ASYLUM, Carlisle.—Junior Assistant Medical Officer. Salary £80, with board.

UNIVERSITY COLLEGE, Liverpool.—Lectureship in Children's Diseases. The emolument is derived from the class fees.

VICTORIA HOSPITAL FOR SICK CHILDREN, Queen's-road, Chelsea, S.W. Ophthalmic Surgeon.

WESTON-SUPER-MARE HOSPITAL.—House Surgeon. Salary £50 per annum, with board and residence in the hospital.

WOLVERHAMPON AND STAFFORDSHIRE GENERAL HOSPITAL, Wolverhampton.—House Surgeon. Salary £100 a year, with board, lodging, and washing.

Births, Marriages, and Deaths.

BIRTHS.

ARNOTT.—On Oct. 9th, at Hamilton-drive, Hillhead, the wife of Surgeon-Major James Arnott, M.D., Grant Medical College, Bombay, of a daughter.

CLARKE.—On Oct. 9th, at Bungay, Suffolk, the wife of G. C. Clarke, L.R.C.P., of a daughter.

HAYES.—On Oct. 12th, at Eversleigh, Sandgate, the wife of J. P. S. Hayes, Surgeon Army Medical Staff, of a daughter.

MATTHEWS.—On Oct. 11th, at S. Owen-street, Hereford, the wife of S. R. Matthews, M.D., of a daughter.

MOUAT.—On Oct. 7th, at Redcliffe-gardens, Southsea, the wife of Surgeon-Major Mouat, M.D., Medical Staff, of a daughter.

POTTER.—On Oct. 11th, at Belsize-terrace, Fitzjohn's-avenue, N.W., the wife of George W. Potter, M.D., of a son.

SMITH.—On Oct. 9th, at Craigholm, Upper Clapton, the wife of Gerard Smith, Surgeon, of a son.

SMITH.—On Oct. 6th, at Kensington-gardens-square, the wife of Dr. Stanley Smith, of a daughter.

MARRIAGES.

CAVENAGH—WHITEHEAD.—On Oct. 9th, at Haslingden, John Paul Cavenagh, of Hull, L.K.Q.C.P.I., L.R.C.S.I., youngest son of the late Francis Cavenagh, Esq., of Dublin, to Annabella, second daughter of Thomas Hoyle Whitehead, Esq., Holly Mount, Rawtenstall.

FASKEN—TOMPKINS.—On Oct. 3rd, at St. Peter's Church, Southsea, William Andrew Durnford Fasken, M.D., Surgeon-Major Bengal Army, to Annie Gregson Tompkins (Dolly), third daughter of the Rev. C. R. Tompkins, Vicar of St. Peter's, Southsea.

FOTHERGILL—ARMOUR.—On Oct. 1st, at Morningside Parish Church, Edinburgh, John A. Fothergill, M.R.C.S., Darlington, to Christian Stewart, second daughter of the late Alex. H. H. Armour, Craigton House, Winchburgh.

GAHAGAN—SMITH.—On Oct. 10th, at Bath-street, Portobello, Edinburgh, Francis Evatt Gahagan, M.B., L.R.C.S.I., Stanningley, Leeds, to Annie Turnbull, youngest daughter of George Smith, builder, Portobello.

LEWIS—HODGSON.—On Oct. 8th, at St. Mary Abbot's, Kensington, Charles Lewis, M.R.C.S., M.S.A., of Folkestone, to Alice Sarah Hodgson, of Cricket-hill, Yateley, Hants, and widow of the late Richard Hodgson, Esq., of Hawkwood, Essex.

PEARCE—ARNST.—On Oct. 15th, at St. Matthew's, Bayswater, by the Rev. Filmer Sulivan, Vicar, assisted by the Rev. O'Brien Hodge, Vicar of St. Peter's, Paddington, Walter Pearce, M.D. Lond., B.S., M.R.C.P., of 63, Montagu-square, eldest son of J. D. M. Pearce, M.A., J.P., Maidenhead, to Christine, eldest daughter of A. Arnst.

PERKS—TREGASKIS.—On Oct. 15th, at Cardiff, Robert Howell Perks, M.D., F.R.C.S., Medical Superintendent of the Adelaide Hospital, Adelaide, South Australia, eldest son of the late Henry Perks, Esq., of Monkton Combe, Somerset, to Frances Mary, eldest daughter of the late Henry Tregaskis, Esq., of Cardiff.

DEATHS.

COCKCROFT.—On Oct. 13th, at Catterick, Yorkshire, William Cockcroft, M.R.C.S., aged 74.

FULLER.—On Oct. 14th, at Wimborne, H. K. Fuller, M.B., M.R.C.S., late of Indian Medical Department, Madras, aged 32.

LOWNDES.—On Oct. 14th, at Catherine-street, Liverpool, Dr. Henry Lowndes, aged 61, fourth and last surviving son of the late William Lowndes, Judge of the Liverpool County Court.

MACKIE.—On Oct. 11th, at Strathview-villa, Brechin, John Mackie, Sen., L.R.C.S. Edin., aged 80.

ROBERTS.—On Oct. 14th, at Alfreton, Theophilus L. Roberts, L.R.C.P. Edin., M.R.C.S.

ROYSTON.—On Oct. 15th, at St. Stephen's-crescent, Westbourne-park, W., suddenly, Charles Royston, M.D., in his 61st year.

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

METEOROLOGICAL READINGS.

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editors."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed to the Sub-Editor.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "to the Publisher."*

We cannot undertake to return MSS. not used.

THE TITLE OF PHYSICIAN, &C.

MR. J. B. PIKE, after alluding to questions of title and vindicating th claim to that of Physician by the Licentiates of the Edinburgh College (having been assured by the College that it is his legal title), and denying the right to it of "the omnivorous M.D.," unless confirmed by a College of Physicians, proceeds to raise various other questions arising out of recent correspondence in our columns, particularly the knowledge of insanity possessed by the average medical man. He says:—

"Another of your writers takes it for granted that the 'average' medical man knows nothing of insanity. At St. Thomas's, and, I believe, at Guy's, there was systematic instruction in that subject twenty years ago. On going with the friend of a patient to an asylum to visit a general paralytic, I was asked by the superintendent, 'Do you know anything about general paralysis?' Of course, some practitioners are not well grounded, as can be seen by reading their certificates; but at the same time any specialist must know that in palpably insane cases it is often the most difficult to put the evidence of insanity in black and white. From another of your correspondents comes the usual jeremiad as to the state of the profession. Oh, for a strong Council, elected by the profession, and acting in its interests! If we had that, titles could be fixed beyond dispute, quackery could be restricted both within and without the Register, the abuse of medical charity could be curtailed, every student could be obliged to pass over that *pons asinorum* of the alienist, general paralysis, and, in fact, a medical millennium might dawn. Meanwhile, we must fight our way as we are able; our own conscience must be our law as to our titles, and we must learn as much about general paralysis as we can."

G. H. G.—We think any public-spirited individual would be glad to make known a "cure" for hydrophobia. But many so-called "cures" have been extolled, and none of them has, so far as we are aware, justified the name.

Mr. H. E. L. Canney.—A solitary case would hardly be of much value.

COCAINE IN THE TREATMENT OF DIABETES.

To the Editors of THE LANCET.

SIRS,—In your last issue Dr. Thos. Oliver gives a very interesting account of his case. But how is cocaine pyrogenic? In cocaine poisoning there is no rise of body heat—at least, in the two cases I have seen there was not. Again, in its physiological action of palliating the effects of starvation, dispelling mental and bodily fatigue, it is not by increased heat, but by reducing the metabolism, that it acts; and, as in the case in question there was no rise of temperature, does not this action account for the decrease of sugar in the urine?—Yours truly,

Oct. 14th, 1889. RICHD. LAKE.

THE GUTHRIE MEMORIAL AT ESHER.

G. R. P.—The marble cross erected at the grave of the late Dr. Guthrie of Esher was the work of Mr. T. J. Williamson, whose artistic skill was placed at the service of the subscribers gratuitously, in token of his esteem for the deceased gentleman.

Messrs. Holden and Byrne.—We know of no paper containing the information since the preparation of a return by the Local Government Board in 1882, for the purposes of the Select Committee of the House of Commons on Police and Sanitary Regulations, and that return is necessarily now out of date, because the number of authorities then having powers in this matter was comparatively small. But of some fifty towns now having compulsory notification of infectious diseases, we may confidently say that not half a dozen included measles in their original Acts. Some few authorities have, since adopting the compulsory system, secured the approval of the Local Government Board to the inclusion of measles amongst the diseases to be notified as a temporary and tentative measure. But these cases are quite exceptional.

Mr. E. Buller.—Our correspondent is far the best judge. So much depends on the amount and length of attendance, the nature of the services, previous charges, &c., of which we are not informed.

LAWN TENNIS, AND WHAT IT DID FOR ME IN 1889: FROM A HEALTH POINT OF VIEW.

To the Editors of THE LANCET.

SIRS,—When the season began in May last, a veteran aged sixty, I thought that my tennis days were nearly numbered. A walk of four or five miles tired me. Aching and burning in my great-toe joints made walking somewhat painful. I had had rheumatism in my right shoulder for months, so that I was kept awake at night; acute pain at the insertion of the right deltoid accompanied elevation of the arm, and the left shoulder was also uncomfortable. My first day's practice at tennis was disheartening. I could scarcely serve over the net (underhand). My strokes were extremely feeble, and an overhead stroke caused agony at the insertion of the deltoid. Nevertheless I persevered, and by the end of May, after several good warmings at tennis, I lost all my pains, my joints were freer, I could run about with less aching of the feet, my strokes were more severe, and I could elevate my arm for an overhead stroke without pain. After another month's practice, playing two or three times only in the week, so as not to tire the arm too much, I was fit for tournament play, and I ended the season with winning, early in September, an open veterans' singles event. The pleasant exercise and exertion of tennis, taken in moderation, not only drove away my stiffness, my threatened rheumatism, and improved my muscular system so that I could walk fifteen miles a day, or play six or eight sets of tennis in an afternoon without undue fatigue; but it cleared my mental faculties, strengthened my perceptions, gave me a better "grasp of the situation," and rendered me more alert in my ordinary work. I still look forward to the enjoyment of future seasons and coming tournaments. A game that will thus renovate a veteran is invaluable from a medical point of view. If used with discretion, it is to the busy man more available and of greater advantage to keep him in condition than cricket, football, or any other game I know, and the accidents that happen to players of lawn tennis are very few, and not of a serious character.

Consider, moreover, the mental attributes which are called into action, especially in single tennis. Wariness and close observation to note every move of an opponent, to discover his weak and his strong points; judgment and rapid decision as to our own play, especially when to "go for the stroke"; artfulness in varying one's tactics; patience and perseverance in hammering away at an opponent; self-reliance; grasp of the situation; accuracy and precision in bringing off delicate strokes;—all these qualities are one after another repeatedly called into action in a game of lawn tennis. And these same qualities applied to the pursuits of daily life go a great way to ensure success. I have noticed, especially after tournament play and its previous training, that my mental faculties, especially my perceptive power and rapidity of judgment, are very greatly increased.

Viewed thus, then, as a means whereby man's powers, bodily and mental, may be brought into and kept in the best possible condition, lawn tennis as an exercise is pre-eminently useful to those who, still in middle life, can keep up their activity; and, since both sexes can join in the game, its value is still further enhanced. I for one owe it a debt of gratitude. I am, Sirs, yours truly,

ALEXANDER WALLACE,
Colchester, Oct. 10th. Physician, Essex and Colchester Hospital.

"SEQUAH" IN MIDDLESBROUGH.

HOWEVER brilliant the achievements of quacks, they appear always pleased by the smallest testimony from anyone having what seems a regular qualification. At Middlesbrough the cures reported are marvellous, and it seems that some of the clergy are reminded by them of the "second coming of our Lord." The clergy are not always very acute in medical matters. But "Dr. Haworth" seems to vouch for the cures of "Sequah." We should like to know a little more about "Dr. Haworth's" own qualifications. Can any cures of the miraculous kind be guaranteed by two or three competent witnesses?

POISON FOR THE PICKING UP.

A PHARMACEUTICAL CONTEMPORARY, writing on the subject of the ease with which arsenic may be obtained, remarks:—"In ordinary circumstances, to obtain a poison of this character from a chemist, various formalities have to be entered into. As recent incidents have shown, there are other ways in which arsenic can be extracted. In the face of these difficulties it seems strange that in certain parts of the country arsenic can be had for the asking or the taking. It is in recent years that the mineral refuse in the Devon and Cornish mines has been worked to obtain the article which has become such a valuable material in various manufactures; in fact, the heaps of refuse previously regarded as waste have been worked over, in order to extract it, and in Cornwall, if anybody wanted to obtain arsenic for a felonious purpose, it would only be necessary to go to the nearest mine and help oneself. Going up the Tamar, for instance, one cannot help being struck with the long "flues" in which the arsenic is deposited. Some of these deposits, as at the Devon Great Consols, assume the most beautiful and eccentric shapes. It upsets this theory that the means to do ill deeds make ill deeds done when crimes in which arsenic is employed are rarely, if ever, heard of where the article is as common as coal at Newcastle."

Africanus.—Has our correspondent tried sulphur internally? For an adult a level teaspoonful of precipitated sulphur in milk may be taken twice a day. If it purges too much it may be combined with astringents. Locally, boracic acid dredged into the stockings is useful for the feet, and prevents fœtor.

Mr. Machin.—The qualifications named are not understood to carry the title "Physician."

ALBUMINURIA.

To the Editors of THE LANCET.

SIRS,—"A Pupil of the late Dr. Graves" has forgotten that albuminous urine was known long before Bright's time, and that in his day the current explanation given of it was what would be expected from the humoral pathology then dominant in medical opinion. Dr. Bright's splendid pathological and clinical observations dealt humoralism such a blow that it ultimately collapsed. But Bright's opinions met with a good deal of opposition from his contemporaries. Among others, Dr. Graves, great and wise teacher as he was, says in the lecture referred to: "*Those persons are wrong who assert that albuminous urine is the result of organic disease of the kidneys.* Albuminous urine is here, as Dr. Blackall observes, merely an indication of a peculiar inflammatory state of the whole system, and not of degeneration of the kidneys. I may observe that this is not always the case; for I could point out examples where albuminous urine is connected with an apparent opposite condition of the system—in fact, a condition demanding the use of a generous diet and tonics." The case was one of post-scarlatinal dropsy. I do not think that the passage proves anything more than that Graves refused to accept Bright's views, denounced his opinions, and clung to the exploded humoral ideas in which he had been bred. I regret that his pupil has made it necessary to show so plainly that in this respect Dr. Graves shut his eyes to the truth. We are not at all in danger of reverting nowadays to the humoral pathology of Blackall and Graves. We look at albuminuria in the light of many new facts not known to these eminent writers, and now by no means well enough known, or their meaning admitted by the general body of the profession. It was in the hope of doing something towards the better diffusion of this knowledge that the discussion at Leeds was held.

I am, Sirs, yours faithfully,
Birmingham, Oct. 12th, 1889. ROBERT SAUNDBY, M.D., F.R.C.P.

A CHEMICAL TEST FOR CHOLERA.

THE Italian pharmaceutical journal (*Giornale di Farmacia &c.*) has, according to the *Monthly Magazine of Pharmacy*, recently published a very singular note by M. Bujwid, with the title, "A Chemical Reagent for Detecting Cholera." In this note the author makes known a process for recognising the presence of the pathogenetic microbe to which cholera is attributed, and for distinguishing it from any other kind of bacterium. This is what he proposes should be done: To the culture broth, 5 to 10 per cent. of hydrochloric acid (ordinary pure laboratory acid) is added. In the course of a few minutes, he says, a violet colour will appear, and may be seen for several days. This reaction is manifested in gelatine cultures which are no more than twenty-four hours old; and, according to the author, it is perfectly characteristic of the presence of the bacillus of Asiatic cholera. As this test is very easy to apply in times of a cholera epidemic, it would be well if some of our Indian *confrères* would see if it answers in their hands. It is almost needless to state that the same test must be applied under similar conditions to other bacillus cultures, and as often as possible, before complete reliance can be placed upon it.

Mr. H. H. Taylor.—We do not think it advisable at the present juncture to insert our correspondent's letter. The proper method of bringing his views before the Commission would be by communicating with one of its members, and offering to give evidence.

Digitized by Google

AUTOMATIC MOVEMENTS OF THE HEAD AFTER STRANGULATION.

DR. KASHKAROFF has published in the *Russkaya Meditsina* an account of some observations on the automatic movements occurring in the heads of very young animals—rabbits and kittens—which have been killed by strangulation. The movements were observed in the heads after they had been severed from the trunk, and consisted in opening and shutting the mouth, movements of the tongue, sucking movements, movements of the neck, of the nostrils, and of the upper lip. These movements are not arrested by the removal of the brain if the medulla oblongata only is allowed to remain. Electrical stimulation of the medulla oblongata of an animal after decapitation causes precisely the same movements as the automatic ones above referred to. The effect of removing the cerebral hemispheres is to increase the excursions of the moving organs. The origin of these movements appears to be the want of nutrition, or so-called "asphyxia," of the medulla oblongata. The observations show that it is in this organ that the nervous centre for sucking movements must be situated.

C. K. H.—The charges made do not appear to us excessive if anything like conscientious work has been done. The small "dots" are often of great value in preventing further decay.—2. The etiquette of dental surgeons charging, or not, medical men for professional attendance is not absolutely fixed, but frequently determined by the circumstances of the individual case.

T. O.—We can hardly express an opinion on a document we have not seen; but such a document as our correspondent describes is not against public policy, and presumably, therefore, may be valid.

CONDEMNATION OF THE INDISCRIMINATE USE OF THE SO-CALLED BRONCHITIS KETTLE.

To the Editors of THE LANCET.

SIRS,—There are many evils incidental to the art of medicine, and among them not the least is the heedless manner in which any practice or treatment advocated by an able and successful man is almost universally adopted by the rank and file in the profession thereof. The steam kettle for affections of the bronchial tubes is an instance, and not the only mischievous one. How it has become so universally and blindly adopted is difficult to be comprehended by anyone who understands the rudiments of physics and has read the first chapters of physiology and of pathology. Experience and observation can have nothing to do with it; for those whose bronchial tubes and minute tissues of lungs are affected are constantly seeking for dry air and declaiming against moist fogs and a high hygrometric state of the air. The workers in manufactories which use steam or vaporised water so as to effect the breathing are ever prone to have lungs and heart affected. All intelligent medical men and other scientific observers have recognised the fact that localities with moist, warm, and still air are the least salubrious for affections of the chest, whereas the dry and movable atmosphere is the contrary. Let anyone ask a patient who sought relief for a chest affection in either Madeira, Glengariff, or Bournemouth, and contrast the answer from a poitrinaire regarding Davos Platz, Malvern, or Mallow. Let any person who believes in the steam kettle try it in his own bedroom. Why, it will upset sleep for nights. Much steam in the air actually prevents aeration of the blood by stopping osmosis. Witness the anæmic state of bleachers and those who are obliged to inhale much steam. Because in the first stage of acute inflammation of the lung tissues the capillary tubes and vesicles become dry and are relieved somewhat by a few whiffs of steam from an inhaler, then, forsooth, every stage and form of bronchitis is supposed to be benefited by inordinate steaming of the bedroom air. There can be no more misleading conclusions, and it only shows, to my mind, how much and what damage the public will submit to. I have seen the bronchitis kettle do harm. I know its use cannot be defended, except by the argument that some have not died from it; and I enter my protest against the empirical manner in which it is applied to diseases of the lungs.

I am, Sirs, yours truly,

JOHN ROCHE, M.D., D.S.Sc.,
Retired Indian Service.

Kingstown.

Mr. C. H. Jones.—It is not satisfactory in an Oxford graduate to use a title not covered by his degree. "C. H. Jones, M.B., Surgeon," is not a bad description. We are assuming that our correspondent has a surgical qualification.

Ignoramus.—It is not usual. But we would refer our correspondent to our remarks on p. 676 of our impression of Sept. 28th.

Mr. Pugin Thornton.—The practice is, we think, objectionable, but is one in which we cannot very well interfere.

MEDICAL FEES AT CORONERS' COURTS.

To the Editors of THE LANCET.

SIRS,—In reply to the letter of "X. Y. Z." in your issue of Oct. 5th, I must say that I cannot understand why there should be any doubt. The assistant is paid by the principal for his services, and, unless there be any agreement to the contrary, all fees earned by that assistant naturally become the property of the principal. The former is working for him, and for him alone, and he obtains a *quid pro quo*.

I am, Sirs, yours faithfully,

Oct. 9th, 1889. JUSTITIA.

ARMY SURGERY IN ITALY.

T.N.—Italians possess an excellent practical work on the science and art of surgery on its military side in the "Manuale di Chirurgia di Guerra" of Dr. Isaac Segré, which, despite its unpretending title, is really an exhaustive treatise, numbering some 600 pages, and provided with admirably executed plates, plans, and drawings illustrative of the text. Brief but comprehensive and clear instructions as to the conduct of the army surgeon in camp or in quarters, in the campaign or on the field of battle, in hospital, or under fire, make up the body of the work—all of them drawn from the best sources, and checked by personal experience. It is now in its second edition (Morano, Naples, 1889), and has attracted the favourable notice of the Italian War Office.

PERINEAL PRESSURE IN CYCLING.

To the Editors of THE LANCET.

SIRS,—The letter of your correspondent, Mr. J. W. Waring, M.B., once more calls up the question of perineal pressure in cycling. In THE LANCET of September, 1884, I called attention to the evils which were, in my estimation, likely to arise from perineal pressure *in the young* if the then prevalent custom of straddling the largest wheel possible were persisted in. Since that time I have heard of several cases of perineal abscess, more than one of stricture, and lately of one case of acute urethritis, which were attributed to injury or irritation caused by the bicycle saddle. But since 1884 a very great change has taken place in cycling, and now, instead of the enormous wheel, the largest that the rider could possibly stretch his leg to form a radius of, we have the small-wheeled "Safety," in which the position of the rider much more nearly approaches that of sitting than standing—as was the case when the large wheel was used—and where much of the weight of the body is supported, as nature intended it should be, upon the ischial tuberosities. Yet notwithstanding this improvement in position of the rider, together with the modern saddle, broad behind, and forming a triangle of soft leather in place of the hard, narrow, horn-shaped saddle of old, which fitted close against the perineum instead of jamming between the adductors of the thighs, as the soft modern saddle does—I say, notwithstanding all these improvements in both bicycle and saddle, a certain amount of pressure is still put upon the perineum in cycling; but that it is sufficient, bar accidents, to cause injury to the healthy subject I am not in a position to admit. I think there can be little doubt that this perineal pressure tends to aggravate the prostatic troubles from which, perhaps, most male cyclists of over sixty years of age suffer; but it is an open question whether the great improvement in general health gained by such cyclists does not more than counterbalance any local irritation so produced. Cycling, as practised in 1884, if persisted in immoderately, must have proved injurious to the young; cycling, as practised in 1889, if indulged in in moderation, may come as nearly to the "unmixed blessing" as any outdoor sport common in this country.

I am, Sirs, yours faithfully,

Oct. 12th, 1889. S. A. K. STRAHAN, M.D., Barrister-at-Law.

PRACTICE IN CAPE TOWN.

M.D. would be glad of information as to the prospect of practice in Cape Town; also condition of climate and other particulars regarding the colony.

ERRATA.—In the notice given last week by our correspondent of M. Chassaing's pepsin at the Paris Exhibition the name was erroneously printed "Chaissaing."—In the letter of "A Pupil of the late Dr. Graves" on Albuminuria (p. 776, twelfth line), for "Bright's kidney with albuminous urine," read "Bright's kidney *without* albuminous urine."

COMMUNICATIONS, LETTERS, &c., have been received from—Dr. Barlow, London; Dr. Dickinson, London; Dr. Mott, London; Sir J. Sawyer, Birmingham; M. Patrouillard, Gisors; Dr. Dockrell, London; Dr. T. Oliver, Newcastle; Dr. Crooke, Birmingham; Messrs. Chassaing and Co., Paris; Dr. Grose, Melksham; Messrs. Cadbury; Dr. Hardwicke, Dovercourt; Dr. Saundby, Birmingham; Dr. Strahan; Mr. N. E. Davies, Sherborne; Mr. J. T. Taylor, London; Mr. C. H. Jones; Dr. Wallace, Colchester; Dr. J. E. Pollock, London; Messrs. Medical Diary for the ensuing Week.

Monday, October 21.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations, daily at 10 A.M.
ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1.30 P.M., and each day at the same hour.
CHELSEA HOSPITAL FOR WOMEN.—Operations, 2.30 P.M.; Thursday, 2.30.
ST. MARK'S HOSPITAL.—Operations, 2.30 P.M.; Tuesday, 2.30 P.M.
HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M., and on Thursday at the same hour.
METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.
ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.
CENTRAL LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M., and each day in the week at the same hour.
UNIVERSITY COLLEGE HOSPITAL.—Ear and Throat Department, 9 A.M.; Thursday, 9 A.M.
MEDICAL SOCIETY OF LONDON.—8.30 P.M. The President's Opening Address.—Sir Andrew Clark, Bart., F.R.S.: On the Non-tubercular Hæmoptysis of Elderly Life.

Tuesday, October 22.

GUY'S HOSPITAL.—Operations, 1.30 P.M., and on Friday at the same hour. Ophthalmic Operations on Monday at 1.30 and Thursday at 2 P.M.
ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 4 P.M.; Friday, 2 P.M.
CANCER HOSPITAL, BROMPTON.—Operations, 2 P.M.; Saturday, 2 P.M.
WESTMINSTER HOSPITAL.—Operations, 2 P.M.
WEST LONDON HOSPITAL.—Operations, 2.30 P.M.
ST. MARY'S HOSPITAL.—Operations, 1.30 P.M. Consultations, Monday, 2.30 P.M. Skin Department, Monday and Thursday, 9.30 A.M. Throat Department, Tuesdays and Fridays, 1.30 P.M. Electro-therapeutics, same days, 2 P.M.
ROYAL MEDICAL AND CHIRURGICAL SOCIETY (at the Society's New House, 20, Hanover-square).—8.30 P.M. Address by the President (Sir Edward Sieveking, M.D.).—Dr. Thomas Oliver (Newcastle-on-Tyne): The Analytical and Clinical Examination of Lead Poisoning in its Acute Manifestations.—Mr. J. Bland Sutton: A case of Ruptured Tubal Pregnancy, with remarks on the Cause of Early Rupture.

Wednesday, October 23.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 10 A.M.
MIDDLESEX HOSPITAL.—Operations, 1 P.M.
ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour. Ophthalmic Operations, Tuesday and Thursday, 1.30 P.M. Surgical Consultations, Thursday, 1.30 P.M.
ST. THOMAS'S HOSPITAL.—Operations 1.30 P.M.; Saturday, same hour.
LONDON HOSPITAL.—Operations, 2 P.M. Thursday & Saturday, same hour.
GREAT NORTHERN CENTRAL HOSPITAL.—Operations, 2 P.M.
UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.; Skin Department, 1.45 P.M.; Saturday, 9.15 A.M.
ROYAL FREE HOSPITAL.—Operations, 2 P.M., and on Saturday.
KING'S COLLEGE HOSPITAL.—Operations, 3 to 4 P.M.; Friday, 2 P.M.; Saturday, 1 P.M.
CHILDREN'S HOSPITAL, GREAT ORMOND-STREET.—Operations, 9.30 A.M.; Surgical Visits on Wednesday and Saturday at 9.15 A.M.
HUNTERIAN SOCIETY.—8 P.M. Mr. F. R. Humphreys: On the Clinical Estimation of the Colouring Matter in the Urine.

Thursday, October 24.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M. Surgical Consultations, Wednesday, 1.30 P.M. Ophthalmic Operations, Friday, 1.30 P.M.
CHARING-CROSS HOSPITAL.—Operations, 2 P.M.
UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.; Ear and Throat Department, 9 A.M.

Friday, October 25.

ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.
CLINICAL SOCIETY OF LONDON (at 20, Hanover-square).—8.30 P.M. Mr. Mayo Robson: Case of Cholecystotomy.—Mr. W. Rivington: Case of Potts' Fracture, with Fracture and Displacement of the Astragalus, followed by Symptoms of Tetanus, which subsided after Removal of the Displaced Fragment.—Mr. W. G. Spencer: Case of Recent Dislocation Backwards at the Elbow of both Bones of the Forearm, irreducible from the Lower End of the Humerus, being held like a Button by a Rent in the Anterior Ligament.

Saturday, October 26.

MIDDLESEX HOSPITAL.—Operations, 2 P.M.
UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.; and Skin Department, 9.15 A.M.

SUBSCRIPTION.

ABSTRACT OF

The Harveian Oration.

Delivered at the Royal College of Physicians, Oct. 18th, 1889.

BY J. E. POLLOCK, M.D., F.R.C.P.

AFTER a few preliminary remarks, the orator entered upon the main subject of his address as follows:—

Working, as it were, in the dark, with but few ascertained facts to fall back on, and theories which were only embarrassing, to be got rid of by ceaseless experiment, by hourly study of natural phenomena and an independent reasoning which took nothing for granted which he could not prove, Harvey left us an inheritance which it is well indeed that we should from time to time examine. We who live in the light of modern discovery are apt to forget the beginnings of our knowledge—the labour by which every step in advance has been gained, the progressive reasoning, the errors which retarded, the opposition which opposed—and to use, almost without reflecting on its past history, the great heritage which has descended to us. ..... Harvey was modest and reverential as the true student who sat at the feet of Nature and learned her mode; not self-seeking nor vainglorious; not triumphant in the overthrow of adversaries. He had fought his fight; he had established his facts, which were accepted by his fellows in this country; he had declined the highest honour which the College can bestow, and committed its presidency to other hands; and now in his age he reposed on his laurels, confident in the truth, and therefore in the eternity, of his views.

On sitting down to record his last wishes he left us these directions: Remember your benefactors; search out nature by experiment. ..... By benefactors I think Harvey meant workers as well as donors; and I would recall to your attention and that of our visitors to-day that our Fellows are all men selected because they have contributed something to our knowledge. There are no drones among them; but, while the Council in its wise discretion selects only a limited number from among its members to add to its list of Fellows, they are aware that among the juniors and others are found earnest workers, busied in advancing knowledge, who will doubtless take their place in the foremost ranks of our pioneers. .....

Let us shortly consider the state of Europe at the period when Harvey was at work. He was teaching in London in 1619, and published his discovery in 1628. The chief feature of the sixteenth and seventeenth centuries was the struggle between Reformers and Catholics, but in the latter part of the sixteenth century the Reformation was already an established fact, and a difference in religious belief was subservient everywhere to political aims. Politically the contest for supremacy was between Spain and France and England, the latter joining hands against the former. Spain was the stronghold of Romanism; but her civilisation was not equal to that of Italy. In Germany, Switzerland, the Netherlands, and England, the Reformation was well rooted, and the Huguenots were powerful in France, while Queen Elizabeth and Henry IV. of Navarre no doubt had this cause at heart. Then followed the time of England's weakness under the vacillating Stuarts, while in France Richelieu wielded the greatest power of the time. In 1620 the most devastating war which Europe has ever witnessed broke out, and for thirty years the various petty States of Germany, played against each other by the greater Powers of Europe, were desolating their country under the name of religion. In 1648 this was concluded by the Peace of Westphalia. While those great events were agitating men's minds, it was doubtless hard for learning to get a hearing. In Italy during the last forty years of the sixteenth century there was uninterrupted peace, and a remarkable advance of literature and academic teaching, in spite of the formation of an Index Expurgatorius by Paul IV. in 1558, the influence of which extended even to England. The great Italian universities of Bologna, Padua, Pisa, and Pavia lost none of their lustre in the sixteenth century, and medicine and mathematics were especially studied, and public libraries were much increased. This feature of the revival of literature was observable in various countries. ..... There can be no doubt that the Reformation was a means not only of shaking off the spiritual tyranny of Rome and opening men's minds to its corruptions, but there was a general awakening of individual judgment and a necessary rebellion against dogmatism in religion or science. Dogmatism is the tyranny of power over mind, of system over independent judgment, and all teaching had hitherto been dogmatic. Men inherited a reverence for opinion sanctified by ancient authority, and had come to believe that time can sanctify error—nay, inquiry was forbidden as a desecration, and thus the finest intellects were lulled to sleep, or terrified by the prospect of certain defeat if innovations were proposed. But great intellects and great discoveries were brought to light in that age. Galileo and Kepler laid the foundation of astronomy—the former being also the first to make a microscope and thermometer. Then we had Bacon in England, who defined the inductive method, although Macaulay has remarked that it has been used in all times and countries; while literature was represented in Spain by Cervantes, and in England by our Shakespeare, Ben Jonson, and Milton. A remarkable investigator of nature—the monk Sarpi, who was imprisoned for his liberal views of religion, and is well known as the historian of the Council of Trent—must here be mentioned. It has been claimed for him that he discovered the circulation before Harvey. He was, like him, a student at Padua under Fabricius; but I cannot, after a study of the most ancient record in Italian, satisfy myself that he knew the motor power of the heart, although he was aware of the valves in the veins, and believed in a circular movement of the blood.

Let us pause for a moment to reflect on the universal movement of science, when many observers are engaged in the simultaneous study of natural phenomena, and on the synchronous nature of discoveries. Davey had indicated the anæsthetic results of inhaling certain gases, but it remained for Simpson in Scotland to discover chloroform, and at the same moment it was claimed for the United States. Is not the latest planet discovered simultaneously in several parts of the world? and who shall say what is the next step in advance? The next step! We are even now on its edge; the sight may not reach, nor even the most vivid imagination compass it, but it is there—imminent though unseen, impending though unsuspected. The movement of science, like that of the glaciers, is always there, and its progress demonstrable; but we do not see it till some grand but unexpected result is announced ..... It is no derogation either from the homage which we to-day render to Harvey's memory to say that his final discovery did not emanate from one mind, but was indeed the culmination of knowledge which, however slow in its advance and interrupted in its progress, was evidently always striving towards a perfect theory of the observed phenomena of nature. But it is necessary to our highest estimation of his work to recognise that the errors which he had to overcome had been stamped with the *imprimatur* of dominant minds, and that from the days of Hippocrates to Galen, and from Galen to Fabricius, who was the master and teacher of Harvey, the greatest philosophers of their day had formulated errors to which they gave the authority of the best teachers of their time..... The structural arrangement of the heart and vessels was known both by Harvey and his predecessors. The two sets of chambers and their alternate contraction had been observed with care, the valves which separate them, and the vicinity of the lungs, each provided with a much larger vessel than was required for their nutrition. The arrival of a current of blood at one side of the heart, and the means of its exit at the other, were recognised, yet how the circuit was completed remained a problem. The alternate contraction of the auricles and ventricles was witnessed by Harvey, but Galen, Aretæus, and the whole Alexandrian school saw it in their vivisections, as did Silvanus in the early part of the sixteenth century, and many others to the time of Servetus, who immediately preceded Harvey, and many of these teachers had opened the living bodies of animals and seen the cardiac movements. Further, we are now aware, and Harvey came to know, that the great veins did not start from the liver, although returning the used blood from that organ. The mode by which the different arteries terminate and the whole venous system of return currents begins was not known to Harvey with distinctness, for I cannot find it in any of his statements. The vessels which we now call *capillaries*, and

Digitized by Google

which intervene between the terminal arteries and the originating veins, were not demonstrated till some thirty years later, when Malpighi, aided by microscopic power, revealed their existence. That the blood did pass, and that the onward current through the arteries filled the veins was known to him without doubt, for without this his "circle" on which the blood moved was not complete; but of the capillaries themselves we have no description.

[Having mentioned the erroneous teaching on these points which prevailed up to Harvey's time, the orator proceeded.]

If this was the teaching which Harvey received at Padua, we can conceive the difficulty of the task that he accomplished, for how many erroneous theories had to be destroyed before the truth was recognised. It is the necessary destruction of received opinions which stifles at the birth the uprising of genius. ..... Harvey was no discoverer by a sudden power of insight; the light did not break upon him as upon Paul, by noonday; there was a certain order of events which preceded his own convictions. He was a worker by inference from facts—what we now call *induction*.

The observations of natural phenomena to which I have called your attention were not all erroneous. Silvius, about the end of the fifteenth century, had inspected the arteries and noticed the valves in the veins. Vesalius was aware of the way in which the valves of the heart and great vessels opened and shut, and he pointed out that the septum ventriculorum was absolutely impermeable. Servetus argued that the pulmonary artery was too large for the nutrition of the lung, and that therefore it had another office. He also noticed that in the fœtus no blood passed into the lungs, and that in the adult the pulmonary blood was crimson. In fact, he may be said to have discovered the pulmonary or lesser circulation. He had his difficulties about the capillaries, but so had Harvey; and although he spoke of a backward and forward motion of the blood, it appears to me from a study of his statement that he knew that the arterial system terminated in the venous. ..... If we were asked, after a careful study of Harvey's treatises and methods, which seemed to be the starting-point of his convictions, we should say that before vital phenomena were weighed and examined the structure of the heart and vessels furnished his first awakenings to the truth. "I see this mechanism repeated again and again in all individuals. I see a similar but single machine of like kind in certain lower animals. I remark that certain doors or valves open only in one direction. I notice in life a contractile motion alternating with another as regularly as the pendulum vibrates from side to side; and I argue that this organ so provided with motor power, and involuntary perpetual action, and guarded mechanism, is a propelling centre of motion, and is, indeed, the mechanical recipient of one current and the origin and outgiver of another." I think this was his line of thought, and that the mechanical aptitude of the heart first struck him; and that the vital phenomena dependent on it came as a secondary revelation. Of these last, indeed, he knew but little. The vast results which arose out of his discovery of the circulation were hidden from his view; but he laid a foundation of facts on which our knowledge of the functions of the whole body absolutely depends.

We must here pause to notice how impossible would have been his task if he had not had recourse to numerous observations of the living body. There were few animals which he did not examine by vivisection, and it is only the truth to assert that without such method he could not have attained to certainty, nor could we have reaped the important fruits of his discovery. Our latest, and perhaps our greatest, pathological achievements would not have been attained without vivisection, of which Harvey was the greatest exemplar, if he were not its originator.....It is to Harvey's fine uncompromising method that we owe much of our modern science. We are to be close and accurate observers; we are to study nature in all her phases; we are to investigate structure, in health and disease; we are to note phenomena of every vital action; with unbiased judgment we are to accept only such facts as are proved by repeated observations; and we are not to permit any theory of even the greatest master to influence our appreciation of the actual. This is high work, difficult work—work which must always be slow, because the phenomena of nature are not apparent on the surface, and because our highest and most cultivated powers do not yet approach the grand simplicity of her method; but it was Harvey's work, and it is the mode which he commends to us his successors. He estimated and knew well the mental effort which it had cost to throw aside the theories and teachings which obscured his way, and the labour which he had to devote to his investigation. Yet he said, and said truly, "This is the way—the only way—to the secrets of nature!" It is known that this announced method, which has descended to us through two hundred years, has acquired strength as it grew older. And while I commend it to you as the humble mouthpiece for the day of the great deceased master, I must say a word as to possible dangers which attend on its absolute adoption. It is applicable to science, and without it there can be no certainty. That which the chemist can analyse, which the microscopist can see, which the anatomist can demonstrate, is true—nay, it is the only truth of its kind. But there is that which cannot be so demonstrated yet may be highest truth; for the spiritual cannot be weighed in a balance, nor can we "by searching find out God."

There is not much to a student of the life of Harvey to indicate his religious belief, but we can state with certainty that after a careful study of the beautiful mechanism of the human body, he arose persuaded of the existence of a creative power. "I perceive," he says, "in the mysteries of nature a kind of image in relief of the omnipotent Creator Himself." We know also that he was humble and reverential, and such an attitude of mind it is which opens the heart and intellect to the reception of the highest truth. It would be mean to imagine that all his work would appear done when he had found the secret of a part of the living machine. We know that he further spent many years—many more years than he had devoted to the problem of the circulation—in investigating the secrets of generation. Here, indeed, he was turned back by an impenetrable problem, as we are. But what hope for the future of science do we not find in his final exhortation to us his successors to search out the secrets of nature by experiment. He had found out one; but he knew how many lay beyond it. To him there was no finality in his discovery; he knew its value, but it was not all. There was much more to do.

We have considered the nature of Harvey's discovery, and the methods which he used; but it is to be remarked that if great observers had not arisen after him, both medicine and surgery must have remained stationary. The machinery for carriage of the blood and the power by which it is conveyed having been demonstrated, it was natural to ask what was the nature of the fluid and to what purpose, and whither was it carried. That lesser circulation by means of which venous was converted into arterial blood by contact of air in the lungs was in evidence; but till the chemical discoveries of Lavoisier and Priestley long after, the uses of the lung circulation remained an unsolved problem. We can scarcely hesitate to affirm that the discovery of oxygen had more influence on physiological science than any other chemical fact whatever. The composition of the blood, the nature of its oxygen-carrying corpuscles, its mode of nutrition of the tissues, its carrying power—alone a wonderful thing to contemplate—by which is conveyed to each secreting organ that which is necessary for its purpose; the order in which each "station," so to speak, is visited by the outgoing current, and the refuse called for at a later period of its circuit; the method by which the temperature of the blood and of the tissues is sustained; the changes which are constantly occurring in its composition; its separate vitality resisting certain agents and decompositions; its resistance to elevated temperatures, and many other peculiarities known to the physiologist, and the subject of the study of many observers at this present day—these are only a part of the view opened to the student of nature by Harvey's discovery.

I desire also to direct your attention for a few moments to certain mechanical results of the same. Regarding the circulation and the structure of heart and vessels as a whole, it will be noticed that the discovery is that of mechanism and a power adapted to work it. As we have just seen, the vital results of blood circulation were as little known as its chemical composition; nor, indeed, could they have been known owing to the deficiency of other knowledge.

[Dr. Pollock then cited, as examples of diseased actions which a correct knowledge of the mechanism of the circulation was capable of explaining, obstruction in the mitral valve, aortic regurgitation, failure of the heart's power due to degeneration of the muscular fibres, the phenomena resulting from embolism, and the various kinds of aneuryam.]

The enumeration of the results to medical science which

Digitized by Google

have been gained by our knowledge of the lesser or pulmonary circulation would in itself occupy the time of many lectures, and such details would be unfitted to our present occasion. But I may be permitted to point out a few of the more obvious. All the phenomena of respiration, oxygenation of the blood, the sources of animal heat, and every disease affecting the pulmonary structures, would be unintelligible were we ignorant of the nature and results of the contact of air with the blood in the lungs. The discoveries of Laennec and those who have developed his system of auscultation in this country, by which every structural alteration has been rendered evident to the senses; the advances made by Stokes, Corrigan, by Latham and Williams, would have been impossible, and accuracy of diagnosis, which has now attained to such great precision, could not have been effected. ..... In close connexion with these observations is the use of anæsthetic inhalations, one of the greatest of discoveries, the crown of modern surgery, without which much that is curative would be impossible of attainment, and which as a preventer of pain must rank as among the most substantial triumphs of our art. Among the latest and most important additions to modern science which would have been impossible without a knowledge of the circulation must be enumerated the discovery of minute microscopical organisms in almost all diseases of the zymotic class, and in tuberculous and other pathological products. It will be well, however, not to build up too hasty theories of disease on even such facts. There is a palpable danger of results being mistaken for causes. The invariability of certain morbid products being found is no doubt a proof of the unchangeableness of the diseased process, but it would be surpassing the limits of the Harveian method of exploration by experiment if we were to assume that in all cases these, and these alone, were the causes. The decay of almost every form of organic life ends in a parasite or lower grade, and it may yet be found that our assumed causes were only results. Certainly in regarding the germ theory of disease we cannot multiply observation and experiment too much, but in theorising as to causes we must also account for heredity, the absence of personal communication of disease between individuals closely exposed, and a number of other facts, such as the influence of age and temperament.

Among the great fruits of modern pathology must be reckoned the discoveries of Koch and Pasteur, and the wonderful prophylactic effects of inoculation by a weakened virus. Already many lives have been saved by this method, and its future is most promising. Now, Sir, it has been asked, and it is a question which we should put to ourselves, what effect have all our discoveries and improvements in medical science had on the general health of the country? Are we a healthier nation? Is there a diminution of disease? And do fewer die? Above all, do more individuals survive through the working and useful periods of life, for if so, this is a national gain of power.

[The orator here quoted elaborate statistics from the Registrar-General's returns to show that a marked decline has occurred in the national death-rate in recent years, and that by far the largest proportions of the years added to human life in England, both of male and female, are lived at those ages when the value of life to the community is greatest. It thus becomes possible, he said, to realise how vast will be the national effects of this reduction of the death-rate, which has added an average of two years to the life of each male born in England and Wales, and nearly three years and a half to the lifetime of every female born. These results the orator thought it was but fair to attribute to increased medical knowledge and to the greater recognition of natural laws of health and disease which have been taught by our teaching and enforced with such authority as we possess. After referring to the greatly lessened mortality from phthisis since the passing of the Public Health Acts, and the increase in mortality at the more mature and advanced periods of life, which he suggested might be due to the cares and worries of a higher civilisation, Dr. Pollock concluded as follows:]

I need not say to such an audience as this that *work*—the due exercise of every function given to us—kills no man, and shortens no life. The causes are to be found in what is called our extended civilisation. We are no longer traders to one country, nor for one or two commodities—but the telegraph has introduced us into a widened sphere; and our merchants have investments in every climate, and enter on risks of a kind so varied, that the knowledge of no one man is sufficient to grasp it. Hence there are the anxieties of extended speculation, and a necessary want of the perfect understanding of each. The knowledge of one kind of trade was formerly "power," and led to prosperity; now we are playing games with all the world. Those who are present know well what part of the organism it is which generally fails under such pressure. The public say it is *brain*, but we know that it is *heart*—the motor power which Harvey studied—although, perhaps, he did not foresee to what pressure a modern civilisation and struggle would subject it.

I have spoken but of the trading class and the speculative class, but all classes of society should learn to counteract in themselves the depressing agents of excessive worry, and to beware of the race which, once entered on, may exceed the best of our powers and ruin the machine.

Presidential Address
ON
OPHTHALMOLOGY AND GENERAL MEDICINE.

Delivered before the Ophthalmological Society of the United Kingdom.

BY J. HUGHLINGS JACKSON, M.D., F.R.S., &c.,
PHYSICIAN TO THE LONDON HOSPITAL, AND THE NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC.

GENTLEMEN,—No professional honour can be more pleasant to me than is the Presidency of the Ophthalmological Society. I thank you for it with all the greater heartiness because I am already very much in your debt for your selection of me to deliver the Bowman lecture of 1885,[1] and to open a discussion on that most important neurologico-ophthalmological subject, optic neuritis.[2] There is no department of medicine which has greater attractions for me than ophthalmology. It was the first subject I specially worked at after my student life, and I still think what I said when giving the annual address, 1877,[3] before the Medical Society, that it was "the luckiest thing in my medical life that I began the scientific study of my profession at an ophthalmic hospital." Many years ago I had the good fortune to be Mr. Hutchinson's clinical assistant at Moorfields. I suppose it is to his example and teaching that I owe the beginning of the little scientific development I may have. At an ophthalmic hospital one has the opportunity of being well disciplined in exact observation. When a physician sees how carefully and precisely ophthalmic surgeons investigate the simplest case of ocular paralysis, he is getting a lesson in exactness, and will be less likely in his own department of practice to deal in such generalities as that a patient's seizure "had all the characters of an ordinary epileptic fit," and more likely to take pains to describe the convulsion, the place of onset, the march and the range of the spasm. I suppose I must have felt myself under the kind of discipline mentioned when I wrote about twenty-three years ago:[4] "Until physicians work at the muscular disorders of various convulsive seizures as carefully as ophthalmic surgeons do at paralysis of the ocular muscles, our knowledge of convulsions will not advance in an orderly way." One meaning of science is exactness, or, as Dr. Buzzard put it in suggesting a name for a celebrated painting, "science is measurement." The ophthalmic surgeon measures the swelling of the discs in optic neuritis, the degree of error of refraction in hypermetropia, astigmatism, &c., and makes exact charts of the field of vision.

Although I do not congratulate you on your present choice, I think it a good thing that the president of this Society should sometimes be a physician. It will encourage physicians, especially young physicians, to work earnestly at the ophthalmological aspect of cases of patients under their care. By doing so they may repay part of the

great debt to ophthalmology which general medicine, and especially neurology, is under. Part of this debt has been paid by Charcot, Westphal, Weir Mitchell, Gowers, Clifford Allbutt, Ferrier, Seguin, Stephen Mackenzie, Bristowe, Wilks, Sharkey, Edmunds, Herbert Habershon, Samuel West, James Anderson, and many other physicians. I would particularly mention Gowers's magnificent work "Medical Ophthalmoscopy," a work esteemed by neurologists throughout the world. The recent researches of Beevor and Horsley on localisation of ocular movements in a particular region of the cerebral cortex of monkeys is an important contribution to ophthalmology as well as to general medicine and surgery.

Since six cranial nerves and the sympathetic nerve supply the eyeball and its apparatus, it is evident that, without a good knowledge of eye diseases, the thorough investigation of very many morbid affections of the nervous system is not to be methodically carried out. It is easy to show that this statement is by no means a mere truism. Unless the physician uses the ophthalmoscope by routine, he will often enough overlook the best evidence—and I am convinced in some cases the only decisive evidence—of gross organic disease of the brain there is to be had; and if, as is most often the case in a physician's practice, sight be good, he will not surmise that there is anything wrong with his patient's optic nerves, and will very likely be incredulous when someone who has looked at them tells him that there is swelling of the discs. It is not very many years since the ophthalmoscope was rarely used except by ophthalmic surgeons. Dr. John W. Ogle was the first physician in this country who used this instrument in the investigation of medical cases. I think it very unlikely that there is to-day a single patient in the National Hospital for the Epileptic and Paralysed whose eyes have not been examined by this instrument.

I was very much struck by the frequency with which Dr. Macewen of Glasgow mentioned optic neuritis in his paper, "The Diagnosis, with especial reference to Localisation, of Intracranial Lesion the Result of Aural Disease," read at the Leeds meeting of the British Medical Association last August. This paper is a most valuable contribution to ophthalmology, otology, and surgery. I urge young physicians to study eye diseases at an ophthalmic hospital or at an ophthalmic department of a general hospital; this nowadays needs no urging on physicians especially interested in neurology. A superficial knowledge will not suffice. Without special knowledge of ophthalmology a medical man may overlook paralysis of a superior oblique muscle altogether—may not know that there is any eye trouble at all; if so, he will misinterpret the vertigo for which his patient consults him. The physician's ophthalmological knowledge should be wide. A neurologist who thought only of those ocular symptoms which pertain to the nerves of the eye and their centres would be thinking too narrowly for practical purposes. Unless more widely trained in ophthalmology, he would overlook hypermetropia as a cause of headache and other nervous symptoms, and might thus treat by drugs a condition only needing spectacles for its cure. Again, the physician may, if he does use the ophthalmoscope, misinterpret what he sees if he does not know the morbid results of strain of hypermetropic eyes on the optic discs; he may erroneously consider swelling of the discs due to hypermetropia as a neuritis signifying serious brain disease, and treat the patient on that hypothesis. I infer that there is some excuse for this mistake when made by a physician, and I confess that I have made it, as I have known more than one highly accomplished ophthalmic surgeon to be, for a time at least, in doubt in such a case.

I hope I shall be pardoned for making one more quotation from the address delivered before the Medical Society; I repeat emphatically that "without a good knowledge of ophthalmology a methodical investigation of diseases of the nervous system is not merely difficult, but impossible."[5] Indeed, no physician will, I submit, doubt this who reads Mr. Swanzy's Bowman lecture, printed in our forthcoming volume of Transactions, a most able and very valuable contribution to both neurology and ophthalmology. I speak again of optic neuritis with gross organic brain disease. I suggest that cases of uniocular neuritis with tumour of one cerebral hemisphere (I have seen only three cases with necropsies) are the cases which, after microscopical examination of the parts concerned, will throw most light on the process by which optic neuritis results from disease of various parts of the encephalon. These cases are most likely to come under the care of physicians. The discovery of this process will be a great gain, not only to ophthalmology, but to neurology also. For, presumably, the process by which the pathological condition for some other symptoms, occurring in cases of gross organic brain disease, is produced is similar. At present there are only hypotheses as to this process. I find that I am sometimes quoted as having concluded that optic neuritis results by vaso-motor action, whereas I have only said, what I still think, that that hypothesis seems to me to be the most plausible of the three hypotheses I spoke of.[6] I would remark that an adequate hypothesis has to explain not the neuritis only, but some other pathological conditions, also produced by intracranial tumours. We may put for answer the more general question, How does a tumour, say of the cerebral hemisphere, produce symptoms not explainable by its destructive action? It is well known that some patients, subjects of optic neuritis, and who for most of their time see well, have frequent temporary losses of sight. It is very remarkable to observe a patient stagger into one's room quite blind and then to find him next minute seeing quite well, although with double optic neuritis. Dr. Samuel West has recorded in our Transactions, vol. iii., p. 136, a valuable case of the kind. So striking and so very definite a symptom demands explanation as much as do epileptiform seizures which often result from the same tumour of the mid-cortex which produces double optic neuritis. Neither of these paroxysmal symptoms can be put down to the destructive action of the tumour. I submit that they depend on diametrically opposite changes; that there is exalted instability of cortical grey matter—a condition induced by the tumour, probably by a local encephalitis, a condition permitting occasional sudden excessive nervous discharges. An acceptable hypothesis has to account for these two symptoms, as well as for optic neuritis. It has still more to account for.

There are other symptoms sometimes occurring along with optic neuritis from intracranial tumour which require explanation; and this I hope physicians will endeavour to give. Dr. Buzzard[7] made the following remarks: "Was it possible.....that the vomiting and the slowing of the pulse might represent an affection of the pneumogastric brought about by the same cause as that which produced optic neuritis, and that the sudden or rapid death which Dr. Hughlings Jackson had mentioned as one of the possible contingencies of optic neuritis from intracranial disease might also be explained by a more severe influence exerted upon the same nerve?" It is very remarkable that many patients with optic neuritis die suddenly or rapidly, and when seemingly in fair general health, sometimes at work, certainly most unexpectedly. I have often urged this on the attention of physicians. In some cases of cerebral tumour the patient may be acutely ill; he may have an illness very like tubercular meningitis in many of its symptoms; there may be slow and unrhythmical pulse and irregular respiration, there are retracted abdomen, constipation, and vomiting. I suppose that when a patient who has post-neuritic atrophy tells us that his sight failed after "bilious" or "gastric" fever, he has had such an acute illness. Dealing with certain cases of optic neuritis in children, Hutchinson wrote:[8] "Nearly always there is a history of a severe illness, which was supposed to be fever, and was marked by delirium and other head symptoms."

The organic or, as one may call them, the "vital" symptoms I have mentioned are of great importance to the physician. Speaking figuratively, a cerebral tumour in producing optic neuritis is trying to make the patient blind; in producing the other pathological conditions, those of the "vital" symptoms, it is trying to kill him. Following up Dr. Buzzard's very luminous suggestion, I advise that when a patient with optic neuritis dies suddenly or rapidly, or dies in an illness with the "vital" symptoms mentioned, the medulla oblongata, as well as the optic nerves and tracts, should be searched microscopically. There is, however, something to be said against the location of the changes under remark in the medulla. It is perfectly certain that the organic parts, although represented directly in the medulla oblongata, are indirectly repre-

sented (represented over again or re-represented) in the mid-cortex of the brain; hence it may be thought the "vital" symptoms spoken of are owing, not to morbid changes induced in the medulla, but to such changes provoked by the tumour in the cortex in its neighbourhood, especially as it is unquestionable that the tumour does produce the changes round about itself on which epileptiform seizures depend. This I think unlikely, especially when the tumour is in one half of the brain. I now wish particularly to mention that, as Fagge[9] pointed out, some patients die of cerebral tumour by rapid respiratory failure. In one case under my care artificial respiration was tried, so respiratory, so to speak, was the condition. I cannot but think that in death by failure of respiration in cases of intracranial tumour there have been morbid changes akin to optic neuritis induced in the respiratory centres of the medulla oblongata. It must be borne well in mind that, strictly speaking, optic neuritis is not a symptom, although it is the custom to call it one, but a pathological condition; often enough it exists without any symptom (defect of sight) attending it. Hence it compares, not with convulsion and the "vital" symptoms, but with the pathological conditions of the cortex or medulla on which they depend.

There is no end to speaking of the integration of ophthalmological and neurological knowledge. The ophthalmic surgeon studying nystagmus is helping towards the elucidation of the nature of tremor, in which the neurologist is greatly interested. Great attention should be paid, both by ophthalmic surgeons and physicians, to the tremor in cases of Graves's disease—one of the four varieties of "vibratile tremor" of Charcot.[10] Work done on miner's nystagmus is valuable to the general body of scientific medical workers, as helping to complete the homologous series of professional spasms, of which writers' cramp is the commonest example. The work the ophthalmic surgeon has done on the symptomatology of cases of paralysis of ocular muscles gives the clue, as Wundt long ago suggested, to the interpretation of incoördinations experimentally produced by destructive lesions of nervous centres in animals. I think it gives the clue also to the interpretation of all disorders of coördination in man, including writers' cramp and other occupation spasms, from negative lesions. It explains the squinting resulting from hypermetropia; I think, too, that it explains the seeming alterations in the size of objects after instillation of atropine and eserine, a thing of importance, since these alterations occur at the onset of some epileptic fits.

In the field of the eye we are most likely to be able to trace the ascending complexity, speciality, &c., in the evolution of movements from the ocular muscles to their representation in most complex movements in the highest motor centres—that is, in the physical bases of visual ideas. Whilst a man is looking at anything, there is at that time engagement of all orders of centres from highest to lowest, and thence on to ocular muscles.

Much valuable material has been accumulated for the study of the evolution of ocular movements by Graefe, Hutchinson, Priestley Smith, Vulpian, Prevost, Ferrier, Horsley, Beevor, and others. We have clinical observations on ocular paralyses from disease of (1) nerve trunks, of paralyses from disease of (2) lowest motor ocular centres (ophthalmoplegia externa), of ocular paralyses (as in lateral deviations of the eyes), from lesions of (3) still higher centres ("motor region" of the cerebral cortex, or, as I call them, middle motor centres), and I hope we shall have such observations of ocular paralyses from lesions of (4) motor centres still higher—the highest motor centres, the physical basis of visual and of other mental states. I have considered this subject in the Bowman lecture (1885).

There is no task I would rather accomplish than this, for by doing it we should do very much towards showing that the organ of mind is sensori-motor, as is the rest of the nervous system. We should thus place the study of epilepsy proper and insanity on a realistic basis. I have long urged a study of the evolution of movements, and first of all in ophthalmic journals. "If such an expression be permitted, there is a gradual increase in intelligence in movements from the lowest nerve trunks to the highest nervous centres." This, written in 1866,[11] expresses crudely what I think can be scientifically stated as a basis for investigation.

[11] Roy. Lond. Ophth. Hosp. Rep., vol. v., Part 4, p. 290.

Alienist physicians, being more than any other physicians directly interested in the anatomy and physiology of the nervous system as they correspond to psychology, are of necessity interested in ophthalmology, and are in great debt to it. I hope they will be interested in the scheme of work suggested on evolution of ocular movements; but I now speak of something more definite. I do not see how any question can be more important or more fundamental in nervous physiology, as it expressly corresponds to psychology, than whether mental states do or do not occur with the "outgoing" current as well as with the "ingoing" current.

Now the battlefield of this question is the case of paralyses of ocular muscles when the full symptomatology of those cases, particularly "erroneous projection," is considered. There are reasons more on the surface why alienist physicians should coöperate with ophthalmologists. Much has been done in the study of ocular symptoms of cases of insanity (Westphal, Allbutt, Wiglesworth), but much remains to be done in this direction. Great good would come from investigation of such an insanity as general paralysis by skilled ophthalmic surgeons conjointly with experienced alienist physicians and other neurologists. I very much wish this joint investigation could be made.

Physicians should try to help ophthalmology by bringing forward cases little likely to come under the notice of ophthalmic surgeons. Cases of spasmus nutans with nystagmus (a variety, I think, of spinal, or rather spinal-system chorea, a symptomatic condition akin to canine chorea) would, as "living specimens," interest all our members. I wish surgeons who see cases of so-called traumatic tetanus would settle whether the muscles of the eyeballs do or do not suffer spasm in the exacerbations of this disease. If the ocular muscles are not involved, their escape is a matter of great importance and significance, especially to neurologists. Physicians and ophthalmic surgeons ought to note the motor condition of the eyes in the tetanus-like seizures sometimes occurring in cases of tumour of the middle lobe of the cerebellum. Very much more could be done by physicians in the observation of the development and the order of development of ocular movements in cases of epileptiform seizures from mid-cortical disease. I hope that Horsley's promised demonstration before the Society of the representation of ocular movements in certain parts of the monkey's cortex cerebri will be a stimulus to our medical members to note very carefully the behaviour of the eyes in the "cortical fits" of man.

I think aural surgeons could bring before us cases of great ophthalmological interest. I have published the case of a man who had ocular movements during a paroxysm of auditory vertigo,[12] and that of a woman[13] in whom lateral movements of the eyes were producible by pressure on a diseased ear. Mr. Laidlaw Purves gave me most important help in the investigation of the woman's case, as did also Mr. Couper. If such cases are met with by Mr. Purves, I hope he will let us see them, especially as he, having great ophthalmological knowledge, would investigate the ocular as well as the aural side of the cases thoroughly. Dr. Kipp, of Newark, New Jersey,[14] has recorded several very important cases of abnormal ocular movements in cases of ear disease. He refers to cases recorded by Bürkner, Urbantschitsch, Jacobson, Gruber, and Moos, as well as to the two I have reported. I think all ophthalmic surgeons will be interested in Dr. Kipp's researches. Speaking of otology, I admit that a knowledge of this department of medicine as well as of ophthalmology is of vast importance to the neurologist. I regret very much that I did not years ago pay as close an attention to otology as I did to ophthalmology, especially as the cases just referred to show that the two are related. Let young neurologists take warning, so that they may not afterwards have like regrets.

I have illustrated the relation of ophthalmology to general medicine by its bearing on neurology; it has, of course, much wider relations. I can best conclude this address by adopting the words with which Dr. James Anderson ends a paper:[15] "It seems to me the best and most hopeful feature of ophthalmology that it has relations, closer or more remote, with every branch of medicine and surgery—indeed, with almost every branch of science."

SOME REMARKS ON

THE NON-TUBERCULAR AND NON-CARDIAC HÆMOPTYSIS OF ELDERLY PERSONS.[1]

BY SIR ANDREW CLARK, BART., M.D.,
CONSULTING PHYSICIAN AND ONE OF THE LECTURERS ON CLINICAL MEDICINE TO THE LONDON HOSPITAL.

MANY years ago, when examining the evidence of the arrestment of phthisis and endeavouring to determine the conditions in which it occurred, I was struck with the large numbers of cases of hæmoptysis occurring in elderly persons who were at the time and remained afterwards free from signs either of pulmonary tuberculosis or of structural disease of the heart. Being in those days completely influenced in my views of hæmoptysis by the teaching of Dr. Walshe, I ascribed every case of pulmonary hæmorrhage in which there was no heart disease or aneurysm, or malignant growth, to tubercular disease of the lung. Perhaps I carried to an extreme issue the opinions of this distinguished master; at any rate, I must confess that the consequences were not satisfactory for the patients or for me. At last, however, there occurred in the wards of the London Hospital a case of fatal hæmoptysis which not only made plain the error of my views, but revealed a cause, hitherto, I believe, unnoticed, of pulmonary hæmorrhage. The patient, a man between fifty and sixty years of age, was admitted for an attack of subacute bronchitis. He had been for many years the subject of a moderate progressive osteo-arthritis, and during the last four or five winters had suffered from severe bronchial catarrh. The attack from which the patient suffered on admission was of the ordinary character; there were signs of some congestion at the posterior bases and of emphysema of the front parts of both lungs, but nothing was found to suggest the existence of tubercular disease. The heart and bloodvessels were sound, there was only moderate fever. The patient was placed upon a light diet and treated with alkalies, alterative aperients, and counter-irritants to the chest. About a fortnight after admission the patient began to cough up blood in small quantities at short intervals, and in spite of all that could be done according to the approved therapeutical teaching of the time—in spite of absolute rest, the strictest regulation of supplies, the application of ice to the chest, and the liberal use of various astringents—the bleeding persisted, and within a week the man died. The post-mortem examination revealed to the naked eye little that was unusual and nothing that was expected. The heart, the larger vessels, and the arterial valves were free from obvious structural change. The bronchial mucous membrane almost everywhere was swollen, congested, violet-coloured, and coated with a muco-purulent secretion. The anterior parts of both lungs were pale, dry, and emphysematous, and curious patches of emphysema surrounded by hæmorrhagic extravasations were noticed in back and lower part of both lungs, which were loaded with blood. Nowhere could there be discovered the smallest evidence of tubercular disease, of any malignant growth, or of any sort of coarse structural change which could account for fatal hæmorrhage. A most minute examination carried out with the aid of the microscope brought plainly to light two important facts. The first was that the seat of the hæmorrhage was in the immediate neighbourhood of the emphysematous patches, and the second was that the minute vessels, the terminal arteries for the most part, were in those localities always diseased. And finally, it appeared in the highest degree probable that there existed a direct causal relationship between the condition of the bloodvessels, the emphysema, and the hæmorrhage. For wherever there was an emphysematous patch there was a diseased artery; wherever the artery was much diseased the capillaries and venous radicles were also affected; and generally, although not always, where the terminal artery was obstructed and degenerating there was adjacent hæmorrhage. Through the observation of these facts and their relations I was led to conclude that the order of events issuing in the hæmorrhage arose and proceeded in the following way. I inferred that the initial visible movement in the malady had been some minute structural change in a terminal branch of the pulmonary or of the bronchial artery, and in consequence of this there had been brought about a more or less complete obstruction of the supply of blood through the territory involved; that following this there arose degeneration of the capillaries and venous radicles determining a true atrophic emphysema, and that the integrity of the bloodvessels being thus impaired, the formation of thrombi or recurrent condition of pressure had brought about the hæmorrhage which ended in death.

Now arose the cardinal question presented by this case, and necessary to be answered if any fresh knowledge were to be derived from it: "What was the intimate nature of the structural vascular changes to which I have adverted? There were two ways of replying to this question, each was distinct in itself, and the one which was most regarded was of the least importance. The small question was, What were the visible characters of the structural alterations in the bloodvessels? The large and crucial question was, What was the nature of the primitive dynamic changes, and which alone gave them form and meaning? In them and not in the vascular changes lay the importance of the case. The structural changes discovered in the affected bloodvessels were limited to nuclear proliferation in the middle coat, and an amorphous and hyaline infiltration of it and of the intima. When I endeavoured to determine the significance of these changes, and for this purpose studied the life history of the case, when I saw that the patient had been for years an arthritic, that he had suffered on many occasions from many of the constitutional manifestations of this diathesis, and that the structural changes in the pulmonary bloodvessels were akin in character to those which are found in the diseased articulations, I permitted myself to conclude that the malady was of an arthritic nature, and that I had seen and dealt with a case of what might be called without serious scientific impropriety, "arthritic hæmoptysis."

About fifteen years ago, in conjunction with Dr. Wall, I had the opportunity of closely studying throughout its course another case of fatal hæmoptysis which in all essential points resembled the case which I have just related. The patient was a stout, fair, florid, healthy-looking man of about fifty years of age. He consulted me for a troublesome bronchial catarrh, and told me that he was rheumatic, and that of late he had been getting fat, short-breathed, eczematous, and indolent. The digestive organs were in fair order, the urine habitually about 1012, but free from albumen and casts; the heart and systemic vessels were free from obvious change, and there were no signs of objective disease in the nervous system. In the lungs there were evidences of general bronchial catarrh, of congestion at both bases, and of emphysema in the front part of both lungs. The finger joints were rimmed or nodulated, a few minute subcutaneous nodules were found in both arms, and eczematous patches existed in various parts of the body and limbs. The treatment consisted of diet and exercise, of occupation and early hours, of alkalies and alterative aperients. The patient became much better, and I saw nothing more of him till twelve months afterwards, when I was summoned to visit him in consultation with Dr. Wall. From him I learned that the patient had relaxed into a careless mode of life, that he had recently caught a severe cold, and that the day before he had been seized with a moderate hæmoptysis which recurred every three or four hours. Such an examination of the patient as was at the time justifiable brought little to light. There existed a catarrhal state of the digestive organs; the urine was still low in density, limpid, and free from albumen; there was no cardiac murmur; the pulse, of fair volume, was about 80; the cervical veins were a little full; and the patient complained of a cough, of frequent frothy, sanguinolent expectoration, and of considerable oppression of the chest. Over the upper portions of both lungs were heard moist mucous râles; over both posterior bases coarse crepitations and increased resonance. The patient was treated in the usual manner by absolute rest, careful feeding, ice to the chest, aperients, and the strongest astringents in large doses at short intervals; but nothing proved of the smallest avail, and on the fifth day the patient became suddenly exhausted and died. A carefully conducted necropsy revealed the appearances of bronchitis, emphysema, pulmonary congestion, and scattered small hæmorrhagic extravasations. And here again, as in the case first related, were found, in significant conjunction

[1] A paper read at the Medical Society of London on Oct. 21st, 1889.

Digitized by Google

the emphysematous patches, the diseased bloodvessels and the extravasated blood. Except that the kidneys were rather small and hard, nothing of moment was found elsewhere. Plainly enough the source of the fatal hæmorrhage lay in the diseased bloodvessels, probably the disease was of an arthritic nature, and, pardonably enough one might venture to say again, here is another case of arthritic hæmoptysis. Since 1875 I have seen in persons over fifty some twenty cases of hæmoptysis of the kind which I have now described, and as in the ordinary annals of medical literature I have been unable to find any clear account of such a variety of pulmonary hæmorrhage, and as the treatment pursued in ordinary forms of hæmoptysis is not successful in this form, I have thought it right, in the hope of further knowledge, to bring the subject to the notice of the profession.

It is not my intention upon this occasion to enter into any systematic account of this variety of pulmonary hæmorrhage, this arthritic hæmoptysis, as I have ventured to call it. But as the cases related have led me to discontinue the ordinary method of treatment by astringents, and to try another method which seems to be more rational, and hitherto at least has proved more successful, I propose to relate two other illustrative cases seen in consultation with other practitioners. Some seven years ago Sir William Jenner, Dr. Wilson Fox, and I were summoned together to consult about a lady suffering from an incoercible hæmoptysis. She was a Jewish lady over sixty years of age, very stout, very "rheumatic," and always ailing. She had nodular finger joints, frequently recurring bronchial asthma, and occasional outbreaks of either eczema or of urticaria. Ten days before our visit, when suffering from an ordinary catarrh without accompanying fever, the patient began to cough up blood, and had continued to do so in small quantities at intervals of three or four hours since. The patient had a somewhat large heart, but there was no murmur, and there was no evidence of systemic arterial disease. Within the previous two days the pulse had become quick and frequent, and the temperature had risen to close upon 100°. In the lungs there were signs of generalised bronchial catarrh, of emphysema, and of basic congestion. The patient complained of frequent cough, of great oppression of chest, and of growing difficulty in expectorating. She had, furthermore, a loaded tongue, thirst, loss of appetite, a swollen liver, and all the signs of a gastro-enteric catarrh. She had been carefully treated by absolute rest, fluid food, ice to the chest, and in succession by lead, gallic acid, and hypodermic injection of ergotin. After full discussion, it was determined that another method of treatment should be tried. The patient was ordered to have a light and rather dry diet, to be sparing in the use of liquids, to discontinue the ice, to have a calomel pill at night, followed by a saline cathartic on the succeeding morning, and to take an alkaline mixture with ammonia between meals twice in the day. Within thirty-six hours the bleeding ceased, and the patient made a speedy and complete recovery. About a year and a half ago the patient consulted me at my house for subacute rheumatic arthritis. She told me that since she saw me first she had had one attack of bleeding, and that it was quickly cured by calomel and salines.

About six years ago I was summoned to meet Mr. MacLaren in consultation about the case of a solicitor who had been suffering from an obstinately recurring hæmoptysis of small amount. The patient was over sixty years of age, had been always delicate and often suffered from incomplete attacks of what was considered to be rheumatic gout. He had rimmed finger-joints, patches of dry eczema, and occasional nervous headaches. A few weeks before our consultation he had contracted a feverish bronchial catarrh and was confined to the house. After a fortnight's cold he began to have some oppression of chest and to be short breathed. This was followed by a small hæmoptysis which gave relief, but the hæmoptysis recurred, and at our consultation there was no sign of its cessation. The patient had no fever and only a slight hurry of circulation. There was a general bronchial catarrh, the fore parts of the lung were emphysematous, and there was some basic congestion, greater on the right side than on the left. The tongue was furred. There was anorexia with some thirst. The bowels were inadequately relieved, and the urine was pale and of low density, but free from albumen. The patient was directed to rest and keep warm, to live upon a light, semi-solid diet, to be sparing in the use of liquids, to be freely counter-irritated over the chest, to have a succession of small doses of calomel at bedtime, supplemented by saline aperients in the morning, and to take between meals, twice or thrice in the day, a mixture containing iodide of potassium, bicarbonate of potassium, and ammonia. This treatment was not particularly agreeable to the patient, who had medical views of his own. Nevertheless, it was adopted, and appeared so far successful that within four days of its adoption the hæmorrhage had ceased. I heard of this patient from a relative some months ago, and I was told, although he led a too sedentary life, he was well and at work

Many additional illustrations of this variety of hæmoptysis could be given, but as in each case there is a close resemblance to each other, and as in all the cases the interpretation of the pathological conditions accompanying the hæmorrhage and the treatment employed for its relief were substantially the same, it would be unpardonable to occupy the time of the Society with the reproduction of details which could prove neither interesting nor instructive to the Fellows. I content myself with having brought to the notice of the Society this curious form of pulmonary hæmorrhage, and believing that a critical discussion of the subject will lead to broader and juster views concerning it. I conclude with a statement of the propositions which I have framed out of the results of my own inquiries.

These propositions are as follows:—

1. That there occurs in elderly persons, free from ordinary diseases of the heart and lungs, a form of hæmoptysis arising out of minute structural alterations in the terminal bloodvessels of the lung.

2. That these vascular alterations occur in persons of the arthritic diathesis, resemble the vascular alterations found in osteo-arthritic articulations, and are themselves of an arthritic nature

3. That although sometimes leading to a fatal issue, this variety of hæmoptysis usually subsides without the supervention of any coarse anatomical lesion of either the heart or the lungs.

4. That when present this variety of hæmorrhage is aggravated or maintained by the frequent administration of large doses of strong astringents, and by an unrestricted indulgence in liquids to allay the thirst which the astringents create.

5. That the treatment which appears at present to be the most successful in this variety of hæmoptysis consists in diet and quiet, in the restricted use of liquids, and the stilling of cough; in calomel and salines, in the use of alkalies, with iodide of potassium, and in frequently renewed counter-irritation.

ON THE

RHYTHM OF THE PRESYSTOLIC MURMUR,

INCLUDING CERTAIN POINTS IN CONNEXION WITH THE PHYSIOLOGY OF THE CARDIAC VALVES.

BY WILLIAM FENWICK, M.D., M.R.C.S.,

AND

WALKER OVEREND, B.A. OXON., B.SC. LOND.,

RADCLIFFE TRAVELLING FELLOW.

PART I.

IN the present paper we communicate the results of some observations on the time of closure of the semilunar valves, and the behaviour of the auriculo-ventricular valves during the course of the cardiac cycle. In the concluding sections we contribute certain facts in regard to the rhythm of the presystolic murmur, with remarks on the causation of mitral obstructive murmurs in general.

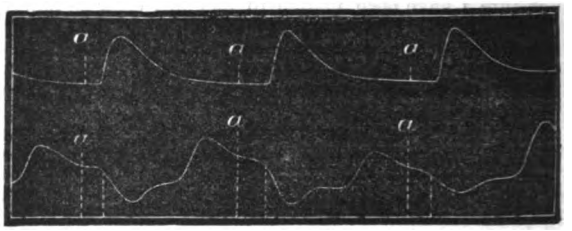
1. *The relation of the aortic second sound to the cardiogram.*—As is well known, Chauveau and Marey[1] introduced elastic bags within the cardiac cavities of horses, and connected them with registering tambours. A small eminence occurring in the curves obtained from the left ventricle, near the end of the descent, which represents the ventricular relaxation, was thought to be due to closure of the semilunar valves. Fredericq[2] auscultated the second sound in the slowly beating hearts of horses, and simultaneously observed

[1] Gaz. Méd., 1861. [2] Centralblatt f. Physiologie, No. 1, 1888.

Digitized by Google

the lever of the cardiograph, writing on a blackened cylinder. His results were in perfect accord with those of Chauveau and Marey. Edgren[3] auscultated the first and second sounds together, and recorded these simultaneously with the cardiographic tracings. He thought the second sound occurred somewhat later—that is, just about the bottom of the descent, which indicates the ventricular diastole. Landois[4] referred the closure of the aortic and pulmonary valves re-

FIG. 1.



Cardiogram from a case of exophthalmic goitre. The lever magnified 30 times.

spectively to two small elevations which occasionally occur in the cardiogram, during the period when the ventricle is comparatively empty but remains contracted (*Verharrungszeit*, Baxt,[5] Moens[6]). Thus, in the cardiogram, represented in Fig. 1, Chauveau and Marey think the closure occurs just before *c* is reached, Edgren about this point, while Landois refers the time of this event to some spot intermediate between the letters *c* and *d*.

It will be profitable, perhaps, at this stage to summarise briefly the views of Martius[7] of Berlin, who has devoted considerable attention to this subject. His interpretation is as follows: The closure of the valves occurs at *c*, thus the period *a*–*c* corresponds to the interval between the first and second sounds. At the point *a* the tension of the auriculo-ventricular valves takes place; at *b* the semilunar valves open, and blood commences to pour out of the ventricles. At *c* commences the *Verharrungszeit*, of which we have already spoken. This period lasts till *d*, when the ventricles commence to relax, and blood to enter them from the auricles. This influx of blood is not represented on the tracing, since the axis of the ventricle now recedes from the chest wall; at the point *e* these two compensate each other, however, and the diastolic filling begins then to make itself manifest. Martius thinks the first undulation, *f*, is caused by the wave of blood, reflected against the root of the aorta, after the arterial beat is over. The elevation, *g*, is due to influx of blood into the ventricle during the auricular systole. When the diastole is long there may be an intermediate rise, which Martius also ascribes to a second wave reflected from the aorta.

In our observations we used a Marey's tambour with button for application to the heart's apex, and connected with a registering tambour. On the same stand as the latter a second registering tambour was fixed, and connected with an indiarubber capsule containing air. The capsule was tapped with the finger synchronously with the first or second sound, as heard through the binaural stethoscope. The rubber tubes connecting the capsule and cardiograph with the registering tambours were of equal length and calibre. In experiments of this kind it has been demonstrated that there is no reaction time,[8] since the mind, once accustomed to the rhythm, anticipates the sound, and the finger makes the signal, exactly at the time of its occurrence. The method is virtually the same as that which Donders[9] used to estimate the time interval between the first and second sound, and with practice the errors of experiment become quite insignificant.[10] Immediately after each revolution corresponding points of the levers were recorded by allowing them to write vertical lines while the cylinder remained stationary. This was done for the purpose of accurate comparison, any other method of determining these points being open to error. In Fig. 2 the lower inscription is a normal cardiogram: the upper registers the second sound. The letters *a a* indicate corresponding points. The result of many series of observations demonstrates the fact that the second sound occurs in the *immediate vicinity* of that portion of the cardiogram which indicates the *commencement of the ventricular relaxation*. It is probable,

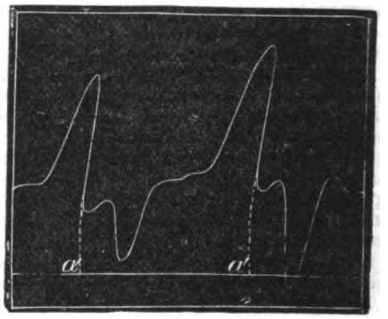


FIG. 2.

however—and we shall emphasise the statement hereafter—that the *actual closure* of the valves takes place immediately after the flow has ceased—that is, about the letter *c* in Fig. 1, while the *sound* is produced at the period we have just indicated. On the other hand, in a case of exophthalmic goitre where no valvular mischief existed, and in which we auscultated both sounds separately, the second sound occurred at the letter *a'* in Fig. 3, corresponding with *c* in Fig. 1. The

FIG. 3.

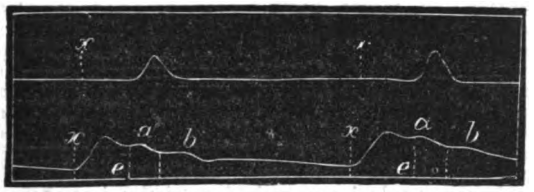
heart was beating 120 per minute; nevertheless the results are trustworthy, since on auscultating the first sound the latter exactly corresponded with the ventricular upstroke. The position of the second sound appears, then, to depend on the amount of aortic tension, and in this way it is possible that the conflicting results of various observers may be explained. This does not affect the sequence of events within the heart itself, since, as we have already insisted, the valves are closed when the flow of blood ceases.

In the cardiogram of Fig. 1, the part of the curve from *c* to *d* corresponds with the empty and contracted final period of Moens. We have assumed the existence of this period, but it is possible that the portion from *b* to *c* at least represents a disfigured part of the cardiogram, the deformity arising from the rush of blood out of the ventricles. No such *Verharrungszeit* exists in curves taken from the excised and bloodless hearts of mammals, and in cardiograms of aortic regurgitation the phase is scarcely recognisable. We venture to suggest that the assumption of such a period is not justifiable, and that the ventricle commences its diastole some time between the letters *b* and *c* (Fig. 1).



2. *The relation of the aortic second sound to the sphygmogram.*—The cardiograph was used to record the carotid pulse, and the signals were made as described in the previous section. Thus, in Fig. 4 *a* represents the predicrotic wave, which in the carotid pulse is always relatively well marked; *b* is the dicrotic eminence. On the upper line the signals are registered, while *x x* are corresponding points of the two levers. On measurement, it is found that the *second sound* coincides almost exactly with the *predicrotic*

notch; and after allowing one-tenth of a second (Waller) for the transit of pulse waves from the heart to the carotid, it is evident that the *sound corresponds with the dicrotic notch.* Since, therefore, the sound occurs previously to the formation of the dicrotic wave, we adopted the following

FIG. 4.

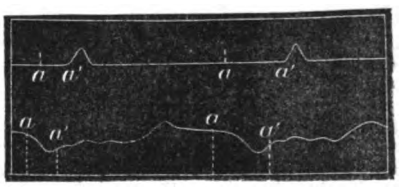
view as a picture of the events which occur *at the root of the aorta* when blood enters it from the heart.

The blood which leaves the ventricle when the semilunar valves open is temporarily lodged in the commencing portion of the aorta, the latter dilating as the result. At the moment when the so-called *Veharrungszeit* of Moens ensues the flow of blood suddenly ceases, and a negative pressure,[11] due to the inertia of the fluid, appears behind the moving column. The aspiration induced by this diminished pressure produces a momentary reflux, which slightly dilates the root of the aorta, and originates the predicrotic wave, while simultaneously closing the valves. By virtue of its elastic walls, the aorta reduces its calibre, and tends to assume, for the moment, a new position of equilibrium, depending on the amount of influx, and necessarily coinciding with a higher position of the recording lever than that immediately preceding the ventricular systole. Having reached this position of equilibrium, however, the aorta passes beyond it (dicrotic notch), and immediately re-expands. During the primary recoil the valves are tightened by the impact of blood, and are set into vibration (second sound);[12] while the secondary expansion generates a new wave (the dicrotic or second beat).[13]



3. *On the mechanism of closure of the auriculo-ventricular valves.*—In order to obviate the possibility of regurgitation, it has been supposed that the flaps of the auriculo-ventricular valves are approximated during the progress of diastole. Paladino[14] thought the curtains were elevated by muscular contraction about the time of the auricular systole, and longitudinal muscular fibres have been described, which run from the auricles into the valves.[15] It has also been suggested that the papillary muscles contract earlier than the rest of the ventricular wall, or may even commence to act during the *earlier* part of the diastole.[16] On the other hand, a mechanical view has been preferred by some physiologists, according to which a reflux of blood takes place during diastole, which, insinuating itself between the valves and the ventricular walls, floats up the curtains into a position better adapted for their early closure. While some authors have thought[17] that the valves become convex to the auricle during the systole of the ventricle, according to others they become horizontal.[18] Kürschner[19] and Purkinje, however, asserted that the valves are drawn down during the systole, and that the complete emptying of the ventricular cavity is in this way secured. Nega,[20] also, states that, having introduced the finger within the beating hearts of calves, the valves were drawn downwards towards the apex of the heart during its contraction. A sphincter-like action of the muscles surrounding the auriculo-ventricular valves has also been described,[21] which must largely participate in their effectual closure.

In order to determine the relation of the contraction of the papillary muscles in point of time to that of the ventricle itself, we opened the cavities of the hearts in rabbits, the latter being removed from the body, and still beating vigorously. It was perfectly obvious that the papillary muscles contract exactly at the same moment as the rest of the ventricular wall. We also cut away part of the wall of the left auricle at a point some distance above the valves, and observed the latter *in situ*, while we supplied the heart with saline solution (0·6 per cent.) at the normal temperature. We observed no movement of the valves during auricular systole. The flaps lie tolerably slack during diastole, and occupy a position intermediate between the axis of the ventricle and its walls. Immediately the ventricular systole begins the flaps are floated up, rendered tense, and come to occupy a horizontal position, there being no trace either of depression of the valves or regurgitation. A slight sphincter-like action at the same time is observable at the auriculo-ventricular orifice, but this is by no means so evident as the results of Ludwig and Hesse would lead one to expect. It is possible, however, that the hearts, in their experiments, after being placed in a hot solution of bichromate of potash, represent a somewhat abnormal or exaggerated condition of the systolic phase. Since the valves remain horizontal during systole, it follows that there must be a certain amount of blood left in the ventricle after each systole is over,[22] and Roy,[23] having introduced the finger through a small opening made at the apex, convinced himself that such was indeed the case. With regard to this question we used the following method. A rabbit is anæsthetised, artificial respiration commenced, and the heart exposed. A moment is selected when the beats are powerful and tolerably slow, and while one of us placed a pair of Spencer Wells' forceps over the left auricle, just above the valves, immediately the auricle has executed its beat, the other clamped the root of the aorta in a similar manner, immediately after the corresponding ventricular systole was over. The heart was then removed, the left ventricle opened, and the clamping of the left auricle tested. We found that there is some residual blood, and think the method, which is quite practicable, might be useful in determining the relation between the amount of the latter and the capacity of the ventricle under varying conditions.

PART II.

4. *The presystolic murmur.* — We were fortunate in securing cases of this lesion, where the beats were regular—a condition indispensable for accurate measurement.[24] Case 1: Eliza A——, aged seventeen. She has not had rheumatic fever or scarlatina. Cardiac dulness not increased on percussion; a well-marked thrill at apex; accentuation of pulmonary second sound; a loud presystolic murmur audible at the apex, beginning immediately after the second sound, and lasting throughout diastole; pulse slow. Fig. 5 represents the cardiogram

FIG. 5.

Mitral stenosis. *a a'*, Corresponding points. *a'* in lower tracing indicates commencement of murmur.

and the signals. The letters *a a'* respectively, in the two lines, represent corresponding points of the two levers. It is obvious that the murmur commences immediately after the depression—that is, at *a'* in the cardiogram. The apex beat was feeble, but three undulations occurring in the

[11] From observations on the veins, Moens concluded that this negative pressure occurs during the systole and coincides with the commencement of the comparatively empty but contracted period of ventricular contraction (Du Bois' Archiv, 1879). Whether the negative pressure which exists when the auriculo-ventricular valves open is a remnant, as it were, of the above—a view we are inclined to accept,—or is produced by a so-called suction power on the part of the ventricle, we cannot here discuss.

[12] Talma (Pflüger's Archiv, 1880) asserts that the second sound is not so much due to vibrations of the valves as to that of the fluid column which is impacted against them. Webster (Journal of Physiology, vol. iii.) thinks that both are factors concerned in its production, but that it is impossible to determine their relative importance.

[13] Burdon-Sanderson (Handbook to Phys. Lab.) showed that a dicrotic wave may occur in a schema devoid of valves. When these are present, however, it is possible that the wave may be intensified. (Rückstonswellen. Landois.)

diastole are fairly well represented. As far as the cardiogram shows, the left auricle does not appear to be hypertrophied, and there were no physical signs of the same.—Case 2: Mary S——, aged thirty-one. She has had rheumatic fever twice; anæmic; apex beat in nipple line; area of cardiac dulness increased; a presystolic bruit, apparently commencing about the middle of diastole and ending abruptly at the first sound. A well-marked systolic bruit; pulse 80 and regular. In Figs. 6 and 7 cardiograms of this case are given. In Fig. 6, when the patient was

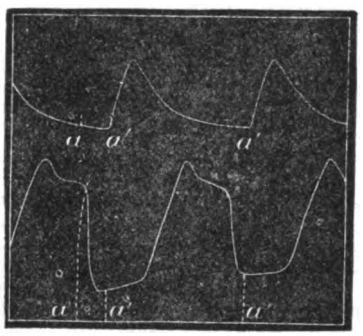

FIG. 6.

Mitral stenosis. Patient perfectly quiet. a' = commencement of murmur.

perfectly quiescent, the murmur occurs immediately before the upstroke, which represents the ventricular systole, and during the auricular beat. After exertion the murmur becomes longer and intensified, as seen in Fig. 7. We

FIG. 7.

Mitral stenosis (same case as Fig. 6) after exertion. a, Commencement of murmur.

have also timed the thrill. We did not find it possible to compare the thrill with the cardiogram in the same manner as the murmur, since the area where the thrill was felt most plainly was encroached upon by the cardiograph itself at the apex. But when one of us signalled the thrill and the other the murmur, we found them to be identical in time.

5. *Causation of mitral diastolic murmurs.*—These murmurs have been classified as "early," "mid," and "late"—that is, according to the position they occupy in the cardiac diastole.[25] The mid-diastolic is identical with the post-diastolic of Hayden. The late-diastolic was first regarded as presystolic by Fauvel (1843), and later, as occurring during the period of the auricular beat, by Gairdner (1862). The early and mid-diastolic have both been attributed to the so-called suction power of the left ventricle (Dickinson,[26] Bristowe,[27] Rolleston[28]). At the present time it seems to be generally admitted that these murmurs owe their origin to the vibration of fluid veins, produced by the rushing of blood through a stenosed orifice into a wider space. If such be the case, it ought not to be a difficult matter to produce such murmurs in the beating hearts of animals. Through the kindness of Professor Schmiedeberg of Strasburg, who placed the resources of his laboratory at our disposal, we were enabled to perform a series of experiments in this direction. A rabbit, having been rendered completely anæsthetic by means of morphia, was fastened to a Czermak's holder, and tracheotomy performed. The tracheotomy tube was connected with an apparatus for artificial respiration, constructed by Miescher of Basle. The chest was opened, the internal mammary artery secured, and the heart laid bare. In the first experiment we passed a curved needle, threaded with fine gut, through the right auricle close to the septum, and tied the ends over the left auricle, thus producing a partial constriction just above the auriculo-ventricular valves. In about forty seconds a distinct presystolic bruit became audible. Since there was some slight oozing from the right auricle, in our subsequent experiments we employed graduated compression over the left auricle, just above the valves, by means of fine forceps. After a short interval, on listening with the binaural stethoscope over the ventricle, a well-marked presystolic murmur was heard. It is obvious, then, that such murmurs may be produced by vibrating fluid veins.[29]

Dr. Bristowe, in felicitous language, has compared these mitral obstructive murmurs to "the fitful or accidental roarings of a continuous torrent," and the question at once arises, What are the disturbing factors which induce these momentary exacerbations of force? We have already remarked that the early and mid-diastolic have been ascribed to a so-called suction power of the left ventricle. In mitral stenosis, however, the cavity of the left ventricle becomes smaller, and its walls tend to become atrophied. The negative pressure of such a ventricle cannot be very significant, and its elastic expansion certainly cannot continue after the auricular blood has entered it; since the latter, held back during systole by the mitral barrier, is increased in quantity, while the capacity of the left ventricle is diminished. On the other hand, it is possible that such a negative pressure occurring in the *right ventricle* in cases where there is a deficient quantity of blood in the vessels (anæmia, pernicious anæmia, Quincke) may be instrumental in the production of the so-called *bruit de diable*. As is well known, this murmur is continuous, or rhythmic and diastolic, increased by inspiration, and conditions, as Chauveau demonstrated, favourable to the production of fluid veins exist in the veins at the root of the neck.

Balfour[30] has drawn attention to the increased pressure which necessarily prevails in the pulmonary circuit in cases of mitral stenosis. This increased tension of itself, we imagine, might lead to the induction of an audibly vibrating jet of fluid, where pathological conditions, as a stenosed mitral orifice, are suitable (fluid vein, Chauveau; pressure steam, Niemeyer). The negative pressure of the left ventricle, granting the existence, too, of stenosis, would only be available as a disturbing factor at the very beginning of diastolic expansion, and we are inclined to attribute the *early diastolic* murmur to the two factors combined—viz., the *vis a tergo* of the pulmonary tension with the evanescent *vis a fronte* of the negative pressure arising in the left ventricle. This early diastolic murmur is sometimes mistaken for aortic regurgitation, and, we believe, it has recently been referred to pulmonary regurgitation (Graham Steell[31]).

In the production of the mid-diastolic mitral the *vis a tergo* of the intra-pulmonary pressure plays the essential part. It may be urged that, if such be the case, the early diastolic mitral should always accompany it. But a little reflection will show that this is not necessarily the case. But we know, as yet, too little about these early diastolic murmurs and their variations to dogmatise. It has been also objected that in mitral regurgitation diastolic mitral murmurs are not present. But at the moment the mitral contains flap back, the ventricular systole being over, there is no constricted orifice to favour the develop-

[25] Vide Bristowe on Mitral Obstructive Murmurs, THE LANCET, Nov. 12th, 1887.

[28] St. Bartholomew's Hospital Reports, vol. xxiv., 1888. Dr. Hilton Fagge thought that in extreme mitral stenosis the auricle begins to contract earlier, and goes on contracting longer. (Guy's Hosp. Reports, 1871.)

[29] Mr. Gotch of Oxford first suggested to one of us the artificial production of a presystolic murmur. Marey (Phys. Méd. de la Circulation, 1863) produced a like murmur, but in an artificial schema, by introducing a perforated plug between auricle and ventricle, but only when the auricular pressure reached a certain height.
[30] THE LANCET, Oct. 29th, 1887. [31] Med. Chronicle, Dec. 1888.

Digitized by Google

ment of a vibrating jet of fluid, although there may be an accumulation of blood in the auricular chambers, and an increased intra-pulmonary pressure. It has been asserted that reduplication of the second sound, audible *only* at the apex, is an impossibility (Bristowe[32]). The latter physician explains the reduplication by a lagging of the aortic valves. But in mitral stenosis, conditions exist which cause the aortic valves to close rapidly—viz., a diminished quantity of blood in the left ventricle, and the pulmonary valves to close later—that is, congestion of the right ventricle. On the other hand, Dr. Sansom[33] distinctly states, and in this he is supported by Dr. Cheadle,[34] that reduplication heard *only* at the apex and *not at the base* is possible. Dr. Sansom thought this was due to vibrations of the mitral valve. We think this is a very probable explanation, since the chordæ tendineæ must gradually become tighter with the progress of the diastole (Ludwig and Hesse).[35] Moreover, the mid-diastolic mitral murmur may run off from this so-called reduplicated sound. With regard to the presystolic murmur, Barclay[36] and Dickinson[37] have argued that this, as a matter of fact, is really systolic. This view presupposes the existence of an incipient noiseless stage in the ventricular beat of the normal heart. Our cardiograms, however, as in Fig. 6, clearly demonstrate that when the presystolic murmur is of a short sudden character, and the beats regular, the murmur commences immediately before the ventricular contraction, as indicated by the rise of the lever. The bruit is thus presystolic, both as regards sound and contraction; and Gairdner suggested that the systole of the auricle gives to the moving column of blood an additional impetus, as it were, which increases the velocity through the stenosed aperture, producing a vibrating jet of fluid, audible as the presystolic murmur. This is undoubtedly the case, and we venture to suggest that a short, rough, presystolic murmur is seldom, if ever, present, unless the auricle is acting well. Dr. Sansom states,[38] he has observed in many cases that "though there has been present a prolonged presystolic murmur, commencing in the long pause immediately after the second sound, cardiographic evidence has shown that the auricular systole occupied its normal position and extent." Such a case we have represented in Fig. 5. The same author[39] relates a case where the auricle was found post mortem to be exceedingly thin, and lined by an old laminated blood-clot. For prolonged murmurs of this kind, we think the increased pulmonary tension is the essential factor; in other words, if the pressure in the pulmonary circuit is sufficiently high, it may induce a combined mid and late diastolic mitral mumur, apart from any auricular assistance whatever. It is obvious, moreover, that there must be an intimate interdependence between the intra-pulmonary tension and the presence or absence as well as the duration of diastolic mitral murmurs. According to Balfour,[40] "whenever the intra-pulmonary blood-pressure gets lessened under the influence of tricuspid regurgitation, then the force of the auriculo-systolic or presystolic begins to fail, and ceases." Sansom[41] also relates a case in which the converse happened; thus, "the systolic murmur which was in the tricuspid area subsequently disappeared, and the presystolic murmur became louder."

Small elevations in the cardiogram, occurring during the diastole, have been already mentioned. By some authors they have been ascribed to the auricular systole, and it has even been asserted that three auricular contractions may occur to one ventricular beat. Gaskell showed that, by clamping the auriculo-ventricular groove, the sequence of the cardiac cycle might be changed, and two or more auricular beats might correspond to one contraction of the ventricle. But these diastolic waves occur in the normal cardiogram, and we have already referred to Martin's explanation of these elevations. But since they occur very frequently in mitral stenosis, where the reflection of waves from the aorta is not so well marked as in the normal circulation, we are inclined to refer them to the influx of blood from the auricle and its subsequent vibration. Moreover, such diastolic eminences are also well seen in cases of free aortic regurgitation (Galabin).[42] The third elevation is evidently due to the entrance of blood during the systole of the auricle itself.

6. *Summary.*—(*a*) The occurrence of the second sound coincides with the commencement of the relaxation of the ventricle, as indicated by the cardiogram. In the carotid pulse curve, making allowance for the time the waves take to travel, the second sound corresponds with the dicrotic notch, and therefore takes place before the formation of the dicrotic wave. (*b*) The auriculo-ventricular valves occupy a horizontal position during the systole of the ventricle, while the papillary muscles contract simultaneously with the rest of the ventricular wall. The ventricle does not empty itself completely, there being a certain amount of residual blood. (*c*) The mid-diastolic mitral murmur in mitral stenosis owes its existence to the influence of the high pulmonary tension. The latter also plays an indirect part in the production of the early and late (presystolic) mitral murmurs; but the immediate exciting cause of the early diastolic is the negative pressure of the left ventricle, while the late diastolic is usually due to the force of the auricular contraction. The murmur and the thrill coincide with each other in the cases we have examined. In conclusion, we embrace the opportunity of acknowledging our indebtedness to Professor Schmiedeberg of Strasburg for the use of his laboratory; also to Professor Burdon-Sanderson, who kindly lent us cardiographic apparatus.

BY F. A. SOUTHAM, M.B.OXON., F.R.C.S.ENG.,
SURGEON TO THE MANCHESTER ROYAL INFIRMARY.

IN a paper on the radical cure of hydrocele, which appeared in THE LANCET, Sept. 10th, 1887, I called attention to the method of treatment by excision of the sac, and described several cases in which this plan had been adopted with very satisfactory results. Since that date I have carried out the same treatment in three additional cases, and as these serve to illustrate some of the conditions in which this method of radical cure is indicated, a brief description of each is given below. A full account of the operation will be found in the article referred to, and further experience has shown that in addition to the ordinary measures for maintaining as far as possible an aseptic condition of the wound, the essentials for success are as follows:—1. A healthy condition of the patient.[1] 2. Removal of the whole of the parietal layer of the tunica vaginalis, so that two serous surfaces are not left in apposition. 3. Complete arrest of all hæmorrhage before the wound is closed. 4. Free drainage for the first few days. 5. Uniform pressure on the scrotum by means of the dressings, in order to maintain the deep surfaces of the wound in apposition. 6. Elevation of the scrotum during the period of healing. If attention is paid to these points, I believe that the operation is attended with little risk, and also that it is the most certain method of radical cure, it being practically almost impossible for a recurrence of the hydrocele to take place.

CASE 1. *Recurrence of hydrocele with adhesion of testis to anterior layer of tunica vaginalis after tapping and injection with iodine; excision of sac; cure.*—The patient, aged forty-four years, came under my care as an out-patient, suffering from a scrotal swelling, which presented all the appearances of an ordinary vaginal hydrocele, except that the testicle was situated at the anterior part of the tumour, forming a distinct prominence on the front of the scrotum. The hydrocele, which had been present for four or five years, had been tapped several times, and on the last occasion, about four months previously to coming to the hospital, it had also been injected with iodine. He stated that after the injection he was confined to bed for ten days,

[42] Guy's Hospital Reports, 1875.

[1] Provided the constitution is sound, the operation may be safely performed in adults of all ages up to sixty years; in three of my cases the patients were aged respectively fifty-three, fifty-five, and fifty-eight years.

Digitized by Google

as the part was extremely painful. As soon as he began to get about, the hydrocele gradually returned, and he noticed that the position of the testicle had altered from the back to the front of the swelling. The patient was admitted into the hospital, and a free incision having been made into the tumour along the outer side of the scrotum, about twelve ounces of clear, yellow fluid escaped. It was then found that the testicle was fixed to the anterior part of the tunica vaginalis by numerous firm adhesions; these were divided, and the whole of the parietal layer of the tunica vaginalis, which was somewhat thickened, was excised with scissors. The wound was closed with sutures, free drainage being provided for by a tube brought out at the upper and lower ends of the incision; on the eleventh day it was healed, and on the fourteenth day he left the hospital. When last seen, six months after the operation, there was no recurrence of the hydrocele.

CASE 2. *Extreme thickening and induration of the tunica vaginalis; excision of sac; cure.*—The patient, aged fifty-five years, came to the out-patient room on account of a scrotal swelling, the size of a fist. He stated that it first showed itself about three years previously and that it had been tapped three times, a quantity of clear fluid being drawn off on each occasion. The swelling resembled an ordinary vaginal hydrocele, except that it was much firmer than usual and quite opaque on examination by transmitted light. The history of the case and the conditions just mentioned pointed to the presence of a hydrocele with a thick sac wall, and this opinion was confirmed on exploring the swelling with a hypodermic syringe, a few drops of clear yellow fluid being drawn off. On account of the thickened condition of the sac the case was considered a suitable one for the excision treatment, and the patient was accordingly admitted into the hospital. On laying open the cavity of the tunica vaginalis several ounces of clear yellow fluid escaped. As was expected, the sac wall was found much thickened (measuring from a quarter of an inch to half an inch in thickness), and extremely indurated, cutting almost like cartilage. The whole of the parietal layer was excised, and the wound then closed with sutures, a drainage-tube being inserted. The wound readily healed except at its centre, where several of the sutures cut through, a superficial granulating surface the size of a shilling remaining. This was still unhealed at the end of three weeks, and did not cicatrise until a few weeks later after its margins had been refreshed under cocaine and brought together by three wire sutures. When the patient was last seen, about three months after the operation, there was no return of the hydrocele.

CASE 3. *Suppuration in tunica vaginalis, and sloughing of sac wall after tapping; excision of sac; cure.*—The patient, aged fifty-eight years, presented himself at the out-patient room, suffering from a painful fluctuating swelling, the size of a cocoa-nut, involving the left side of the scrotum, the tissues of which were œdematous and inflamed. He stated that he had been troubled with a swelling for about three years, and that it had been tapped eight or nine times. A few days after the last tapping, which had been performed a fortnight previously to coming to the hospital, the scrotum began to swell and become extremely painful. The inflamed condition of the scrotal tissues, the fluctuating nature of the swelling, and its rapid reappearance after tapping, all pointed to the presence of pus in the cavity of the tunica vaginalis, and the diagnosis was confirmed by an exploratory puncture with a small trochar and cannula. The patient was admitted into the hospital, and a free incision having been made into the swelling, about ten ounces of thick purulent fluid escaped from the cavity of the tunica vaginalis. As the tunica itself was much thickened (being coated over with layers of lymph, and presenting in places a sloughy, almost gangrenous, appearance), the whole of its parietal layer was removed by means of scissors. The cavity, having been washed out with carbolic lotion and dusted with iodoform, was plugged from the bottom with strips of lint dipped in carbolic oil, no attempt being made to close the wound on account of the inflamed condition of the scrotal tissues. It rapidly granulated up from the bottom, and the patient left the hospital at the end of a fortnight with the wound almost healed. When last seen, twelve months subsequently, he was free from any recurrence of the hydrocele, the seat of the operation being marked by a depressed cicatrix.

Manchester.

A CONTRIBUTION TO THE

STUDY OF CHRONIC VALVULAR DISEASE OF THE HEART,

BEING

AN ANALYSIS OF ONE HUNDRED AND FIFTY CONSECUTIVE CASES SEEN AT THE GLASGOW ROYAL INFIRMARY DISPENSARY, WITH A SPECIAL LIST OF CASES BEARING ON THE INFLUENCE OF PREGNANCY IN CHRONIC VALVULAR LESIONS.[1]

BY GEO. S. MIDDLETON, M.A., M.D.,

ASSISTANT PHYSICIAN TO THE GLASGOW ROYAL INFIRMARY, ASSISTANT TO THE PROFESSOR OF PRACTICE OF PHYSIC IN THE UNIVERSITY OF GLASGOW, ETC.

THE analysis on which this paper is based was originally prepared for presentation to the Glasgow University Medico-Chirurgical Society, one of my chief objects being to bring before the students the subject of cardiac valvular disease from the dispensary point of view, so as to give them a less unfavourable impression of these diseases than they are apt to derive from the cases seen by them in the hospital wards. The analysis has since been extended, and it has been thought that, though the numerical basis is too narrow for definite generalisations, the statistics and the facts brought out by them are of sufficient interest to be placed on record.

The cases on which this paper is based were seen at the dispensary or out-door department of the Glasgow Royal Infirmary during a period of thirty-four months in the years 1885–89. Cases of cardiac disease without murmur, of anæmia and of chorea with murmur, and of aneurysm of the arch of the aorta have been excluded from consideration, and only those have been brought under review in which a diagnosis of chronic valvular disease was made. Those who are conversant with the amount of work that has to be done at the hospital dispensaries will be aware of the possibility of errors in diagnosis having been made, partly from the necessarily brief time that can be devoted to each case, and partly from the fact that, as many cases are only seen once, there is no opportunity afforded of correcting or modifying the diagnosis. But care has been taken, as far as possible, to exclude all doubtful cases from these statistics. Bearing this in mind, then, I would direct attention to various points in connexion with valvular disease educed from an analysis of these cases.

Frequency.—The total number of cases was 150, which may be taken as certainly not less than one in 40 of all the new cases seen, which seems a large proportion. When we remember the number of cases excluded from review in which the heart was more or less involved, this would indicate a very large proportion of cases in which the condition of the heart has to be reckoned with as part of the disease.

Sex.—Of these cases, 78 were males and 72 females. Rather more males than females seek advice at the dispensary, so that these numbers probably indicate an equal liability to cardiac disease in the two sexes—a statement, however, which will be modified later.

Age.—From an analysis of the ages of the cases it would appear that up to the age of forty females are more liable than males, and it is worthy of note that in each of the first four decades of life the number of females exceeds the number of males. After the age of forty, on the other hand, the males affected greatly outnumber the females, the excess in this case also being observed at each decade. So far, then, as these statistics go, age would seem to have a considerable influence on the incidence of cardiac disease on the two sexes.

A. TABLE OF AGES.

The greater frequency in females during the first four decades is probably to be referred to the fact that females seem to be more liable to rheumatism than males (see below). The increased frequency in males after forty, on the other hand, may with probability be referred to the effects of degenerative changes (partly due to the mode of life as regards various excesses) and of strain from heavy work, these showing themselves in the most marked form in the fifth and sixth decades, when the wear and tear of life may give rise to valvular lesions without the intervention of rheumatism. This view will receive some confirmation when we come to consider the influence of rheumatism and the incidence of the various valvular diseases on the two sexes. The relative infrequency of valvular disease after sixty years of age may reasonably be attributed to death having already claimed many victims.

Causation.—In determining the causation considerable difficulty was frequently encountered, the class of people with whom we are dealing being in general ignorant, and inattentive to the influence of long-antecedent events in their lives. As will be seen from the table, however, in a very large number, 63, a history of rheumatic fever was obtained, thus confirming the view generally entertained as to the influence of this disease in the causation of cardiac affections. Bearing in mind that cardiac disease not unfrequently follows the mildest attacks of rheumatism, direct inquiry elicited the fact that thirty others had been subject to more or less severe so-called rheumatic pains or to

B. TABLE OF CAUSES.

Rheumatic fever in	63 = 42 per cent.	94, or 62·6 per cent.
Rheumatic pains in	30	
Gonorrhœal rheumatism in	1	
No rheumatic history in	56 (or 37·3 per cent.)	
History of strain in	6 (5 aortic).	
,, ,, bronchitis in	3	
,, ,, fright in	2	
,, ,, fits in	3	
,, ,, chorea in	1	

severe growing pains, and that one had had gonorrhœal rheumatism. There is thus a total of 94, or 62·6 per cent., in whom rheumatism might be suspected to be the cause. In 56 cases there was no history of any kind of rheumatic attack, and very few of these could offer any suggestion as to the cause of their disease. Six of them referred their condition to strain or hard work, and there can be little doubt that that is a tolerably fruitful source of cardiac disease, especially aortic, as we shall see. Two blamed a fright, which may be supposed to have given origin to symptoms from a previously latent disease. The same may be said of the cases in which fits were accused. The bronchitic cases are readily explained, the lesion being tricuspid regurgitation. The case attributed to chorea is included in the list, because the chorea dated many years back, and the lesion was mitral stenosis.

With regard to the 63 cases that had suffered from rheumatic fever, it is very noteworthy that there was a marked disproportion between the sexes, there being only 23 males, as against 40 females. Of those, on the other hand, who had a history of rheumatic pains, 17 were males and 13 females, and those without rheumatic history numbered 37 males and 19 females. These figures tend to support the view that rheumatic fever is more common among females than among males.

The average age of 23 males with a history of acute rheumatism was thirty-seven years, of 17 with rheumatic pains forty-one years, and of 37 with no rheumatic history forty-five years; while of the females 40 with a rheumatic history gave an average age of thirty-four years, 13 with a history of rheumatic pains an average of thirty-seven, and 19 without rheumatic history an average of thirty-five. The only point of note in this respect is the difference among the men of the average age of those with and without a rheumatic history.

Incidence of disease on the various valves.—This will be seen from the annexed table. The most outstanding feature of these numbers is the comparative immunity of the valves on the right side of the heart. It is, of course, well known that in extra-uterine life the valves on the right side are extremely rarely primarily attacked by disease; but it is also generally recognised that tricuspid regurgitation is by no means a rare consequence of old-standing bronchitis and of mitral stenosis. Considering the number of cases of chronic bronchitis that present themselves at the dispensary, and the number of mitral lesions above recorded, it is a matter of surprise to me that I have met with so few instances of tricuspid regurgitation, especially as I have been on the look out for that lesion. Of the seven cases seen the three pure cases occurred in association with chronic bronchitis, and the other four in combination with mitral lesions. The one case recorded as probably stenosis of the pulmonary artery was regarded as congenital, and it was supposed that there was in addition patency of the foramen ovale or of the inter-ventricular septum. An account of the case was published in the *Glasgow Medical Journal*, July, 1888. The statistics further show the great preponderance of affections of the mitral valves, there being 80 cases of pure mitral lesion, as against 46 of pure aortic. It is generally believed that the mitral valve suffers most from having to bear the strain of the ventricular systole; but this applies only to cases of rheumatic endocarditis. Of the 80 mitral cases there were 55 with a history of acute rheumatism or of rheumatic pains, while of the 46 aortic only 27 had such a history. The table further indicates a great majority of females affected with mitral disease, the respective numbers being 48 females and 32 males, which may be accounted for by the greater prevalence of rheumatism among the female patients, as indicated above. The large number of cases in which pure mitral stenosis occurred is also worthy of note. The ages of the patients with pure mitral disease are given in the following table,

C. TABLE SHOWING VALVES AFFECTED.

Mitral	Pure stenosis: males 10, females 20 =	30
	Pure incompetency: males 21, females 15 =	36
	Combined stenosis and incompetency: males 1, females 13 =	14
		80
Aortic	Pure stenosis: males 3, females 3 =	6
	Pure incompetency: males 4, females 3 =	7
	Combined stenosis and incompetency: males 27, females 6 =	33
		46
Mixed aortic and mitral lesions: males 9, females 7 =		16
Mixed mitral and tricuspid lesions		4
Tricuspid.—Pure incompetency		3
Pulmonic.—Stenosis (?)		1

D. AGES OF CASES OF PURE MITRAL DISEASE.

Age.	Males.	Females.
1 to 10	0	2
11 to 20	4	10
21 to 30	10	13
31 to 40	2	10
	16	35
41 to 50	10	7
51 to 60	3	5
61 to 70	3	0
71 to 80	0	1
	16	13

which also shows the greater liability to mitral disease that females lie under up to the age of forty, thus accounting for the greater frequency of cardiac disease in females in the first four decades, as already pointed out.

When attention is directed to the cases of pure aortic lesion, the first thing that strikes one is the comparative infrequency of cases of single lesion, as contrasted with the number of cases of single lesion of the mitral valve. Yet the fact that six cases of pure aortic stenosis were observed seems to me to indicate a larger proportion than might have been expected, considering the well-known infrequency of that as a lesion by itself. As was to be anticipated, most of the aortic cases presented the double murmur. The disproportion between the sexes is extremely striking, and is also brought out in the annexed table, which takes account of all the double aortic murmurs met with, whether purely aortic or combined with mitral disease. From this it will be seen that, between the ages of thirty-one and sixty, there were 24 males as against 8 females, a disproportion due, I believe, to the fact that males are so much more liable

E. CASES OF AORTIC DOUBLE MURMUR.

than females to disorders of the valves arising from strains. This may be inferred from the history of these cases; of the 24 males, 12 had no rheumatic history, 5 had had rheumatic pains, and 7 had had acute rheumatism; while of the 8 females, one had no rheumatic history, 2 had had rheumatic pains, and 5 had had rheumatic fever.

In contrast with the great frequency of valvular disease may be mentioned the fact that during the period under survey only three cases have presented themselves in which pericarditis was suspected, exclusive of cases in which pericardial adhesion might have been present. In one of these there was pericardial effusion along with endocardial mischief, and the case proved fatal a few days after being seen. In two others there was a suspicion of pericardial friction. It is to be supposed that, in the stages of friction and effusion, cases of pericarditis are too ill to undertake the exertion of a visit to the dispensary, those conditions generally coming on in the midst of an acute attack of rheumatism, and not developing out of the indefinite seizures that frequently give origin to valvular disease.

Symptoms.—I do not propose to discuss the well-known symptoms of cardiac disease, but I wish to direct attention to a few points in regard to these. The first is the absence of severe or even of any symptoms in many cases—a fact which was emphasised in that remarkable paper which Sir Andrew Clark read at the Brighton meeting of the British Medical Association.[2] Many of my cases did not spontaneously complain of symptoms suggestive of cardiac disease, but in the great majority direct inquiry elicited a history of some cardiac symptoms or indications at a past date. Giving a much more liberal interpretation to what may be regarded as indications of cardiac affections than was done by Sir Andrew Clark, I find that in only 24 out of the 150 cases could absolutely no history of symptoms be obtained. In these and in many others the valvular mischief was discovered through examination of the heart being practically made a part of the routine to which patients are submitted.

Among the less common conditions suggestive of cardiac origin I would point out such as hæmaturia, of which there were two cases, and enlarged and painful spleen, of which there was one case, these being all regarded as of embolic origin. The only other embolic lesion noted was hemiplegia, of which there were seven cases, who were either suffering from that when seen or had a history of previous seizures. Besides these it may be noted that in one case melæna was a prominent symptom, and in three epistaxis. In one case an aortic lesion was associated with painful cramps affecting both legs and the left arm, which at first I was inclined to suppose might indicate embolism, but further observation tended to that idea being discarded. In three the disease was associated with fits, in one with purpura hæmorrhagica, and in one with herpes zoster.

Prognosis.—The question of prognosis resolves itself into a determination of the duration of the disease. Now, in the class of patients with whom we are dealing there is great difficulty in discovering when the cardiac disease originated, the great majority of them being quite ignorant of the fact that any such disease was present. Some were able to tell that the heart had been said to be affected at the date of some previous illness; but generally reliance had to be put upon the date of a rheumatic attack and the date of origin of symptoms as guides in determining this point, and it was found that the history was more clearly obtained in mitral lesions, and especially stenosis, than in any others, from the frequency with which hæmoptysis occurred as an early symptom. In regard to this relation to rheumatism, however, it must be borne in mind that, perhaps not unfrequently, cardiac valvular lesion develops, not at the time of a rheumatic attack, but some time afterwards. It must also be premised that the cases were but rarely followed up to a termination, so that the actual duration could seldom be determined.

In 41 cases, or 27 per cent., the disease had in all probability lasted five years at least, and in 22 of these for ten years or more—viz., 7 aortic (6 double murmur, 1 pure regurgitation), and 15 mitral (6 stenosis, 8 incompetency, and 1 the combined lesion). These figures tend to confirm the teaching of Dr. Gairdner, that mitral lesion (perhaps especially mitral stenosis) is the form of valvular affection which is most compatible with prolongation of life.

(To be concluded.)

ON A CASE OF

UNUNITED FRACTURE OF THE RADIUS SUCCESSFULLY TREATED BY THE GRAFTING OF RABBIT'S BONE.

By A. F. McGILL,

PROFESSOR OF SURGERY IN THE YORKSHIRE COLLEGE, AND SURGEON TO THE LEEDS INFIRMARY.

THE treatment of ununited fracture of one of the bones of the forearm has, as far as I know, always been unsatisfactory. The reason is not difficult to find. In performing the usual operation of resection, it is necessary to remove portions from the end of each fragment, and it is then impossible to get the two portions into apposition. If the radius is broken the ulna prevents apposition, and if the ulna, the radius. To overcome this difficulty it has been proposed to cut down on the unfractured bone and remove a piece corresponding in size to the gap left by the resection. The bones being then wired there seems to be no reason why union should not occur. I have treated one case in this way, but the result was unsatisfactory. When the case which is the subject of this paper came under my care, it occurred to me that it was advisable to follow the line of treatment first suggested by Dr. MacEwen in a case of destruction of the shaft of the humerus from acute necrosis—viz., the building up of new bone by the transplantation of bone fragments. The fragments in my case were taken from a young growing rabbit. The following are the notes taken by Mr. Kellett:—

J. N——, aged twenty, was admitted into the Leeds Infirmary, under the care of Mr. McGill, on March 9th, 1889, suffering from an ununited fracture of the right radius. In February, 1888, he fractured his right forearm; the fracture was compound, the wound being on the radial side. Through the wound the broken ends of the radius protruded. The ulna united perfectly, but the fragments of the radius would not join. Three months after the accident a surgeon exposed the ends of the bone, refreshed them, and wired them together. The wound healed, but the fragments did not unite. On admission, the radius was found to be fractured at the junction of the lower with the middle third. Over this position is the scar of a perfectly healed wound about two inches and a half in length. The two fragments of the radius are absolutely ununited, the utility of the forearm is much impaired, flexion of the fingers and adduction of the thumb being most imperfect. On March 19th, an Esmarch's bandage having been applied, Mr. McGill made an incision two or three inches in length in the situation of the old scar. Having exposed the ends of the bone, he found that there was no sign of union, and that the two fragments were rounded at their extremities and covered by a thick membrane resembling periosteum. This was removed by means of a file, and bone tissue was thus bared. When this part of the operation was complete, an interval of about three-quarters of an inch was left between the fragments. In the meantime a rabbit, six weeks old, had been killed, and small portions, one or two lines in length, had been chiselled from its femur. With these the interval between the fragments was filled up, thirteen pieces being inserted. The bones were not wired together. The skin wound was stitched up tightly with numerous catgut sutures. No drainage-tube was used. Firm pressure was applied by means of salicylic wool and bandages, and the forearm was placed on an anterior splint. The elastic tourniquet was not removed till the dressings were applied. On March 29th, the tenth day after the operation, the wound was dressed for the first time. There was no suppuration and very little discharge; the wound had healed, except a small superficial spot. The wool dressings were continued till April 16th, when there was slight irritation of the skin; they were consequently discontinued. The patient left the hospital on April 27th with the bone firmly united. In August he was shown at the meeting of the British Medical Association, when the injured arm was as useful as the other.

CHLORALAMIDE.

BY D. R. PATERSON, M.D., M.R.C.P.

TWENTY YEARS have now passed since Liebreich introduced the hydrate of chloral to the notice of the medical profession as a trustworthy and efficient sleep-producing agent. In that time its fortunes, like those of all new remedies, have fluctuated greatly. From the outset the marked hypnotic power possessed by the new drug, standing out, as it did, in such bold relief, led in an incredibly brief period to its recognition as a remedy of the utmost value. Scarcely, however, had twelve months gone before it became known that chloral exerted a powerful influence on the circulation, and reports of cases presenting alarming symptoms, and not infrequently ending in death, soon rendered imperative the exercise of the utmost caution in its administration. Since that time many substances have striven to displace it; most of them, indeed, do not affect the blood-pressure or heart, but none of them command its somnifacient power. Therapeutists are still in want of a hypnotic which shall at once be efficient and safe, and it is with the hope of achieving this desirable end that Professor von Mering has brought forward the latest claimant for consideration, to which he has given the name of chloralamide. Chloral formamide or chloralamide is a synthetical product derived from chloral anhydride CCl_3CHO, and formamide CHO,OH_2, and has the formula $CCl_3CH <^{OH}_{NHCHO}$. It forms colourless crystals, and is said to be soluble in nine parts of water and in one and a half parts of 96 per cent. alcohol. The taste is mild, slightly bitter, but not astringent, while the aqueous solution which ought to be produced by a temperature not exceeding 140°F. is stable. Neither the alcoholic nor the aqueous solution is altered by the addition of nitrate of silver or weak acids. On the other hand, the caustic alkalies readily decompose it, the alkaline carbonates more slowly. As a consequence, chloralamide cannot be given in alkaline solutions, but may be administered in weak acidulated ones. Experiments have shown that its physiological action is on the higher cerebral centres in the first place, the lower being only slightly affected, and that much later. Kny[1] injected frogs with ¾ gr., which produced after twenty-five to thirty minutes a drowsy state, in which the reflexes were considerably diminished, though not abolished. In the course of two or three days the animals had fully recovered. Doses of 25 to 45 gr. given to rabbits by the stomach induced after an interval of twenty to twenty-five minutes a deep sleep of from ten to twelve hours' duration, from which the animals awoke quite lively. In one instance a rabbit, thirty-five minutes after a dose of 25 gr., lay fast asleep on its side, twitching only on strong irritation, the heart beating powerfully, and the respiration being deep, regular, and twenty-four in the minute.

With the view of testing the efficacy of the new remedy, I have given it in fourteen cases of insomnia, including simple sleeplessness and that resulting from phthisis, heart disease, enteric fever, &c. These trials were all carried out in hospital patients. Each case was watched by the nurse previous to and after the administration, the duration and the character of the sleep being noted, while the patient's statements were compared with these data and checked. The doses ranged from 15 gr. to 45 gr. dissolved in warm water, the addition of a few drops of rectified spirit increasing very materially the solubility, which is hardly as great as the figure given above. I may say here that several observations were made on the temperature, pulse, respiration, and urine, with a negative result. Taking first the results in simple insomnia, we have four cases in which the drug was given, two of them being above sixty years of age. In one instance—an old woman of sixty-four, who had not slept for some time, and used to spend the night sitting up in bed—30 gr. produced on consecutive nights, after an interval of from thirty to forty minutes, a tranquil sleep of eight and nine hours respectively. On both occasions there was some giddiness on awakening, while on the second morning, in addition, she felt sick and remained drowsy during the forenoon. The dose being then reduced to 15 gr., sleep did not result on an average earlier than from half an hour to an hour and a half. It lasted, however, nearly eight hours, and was free from any of the former unpleasant after-effects; in fact, after taking half-a-dozen doses, she stated her appetite was much better than it had been for some time. A man sixty-two years of age, convalescent from an attack of jaundice, and complaining much of resting badly at night, received 30 gr. on several occasions. A sleep of eight hours on an average ensued in from forty to seventy-five minutes after administration. The sleep was unbroken and very sound, and he declared it removed the dull headache from which he had been suffering. Here the drug was used on alternate evenings, and clearly showed its beneficial effect. In a woman aged fifty, 30 gr. doses were followed by from seven to eight hours' sleep, and disappearance of a paroxysmal cough which was very troublesome. After the first dose there was next morning a feeling of sickness, but this, however, was not observed on any subsequent occasion. The fourth case was a man who had been carefully watched, and was absolutely sleepless for some days after his admission to hospital. Doses of 15 gr. to 30 gr. induced from two to four hours' rest on several occasions, and were sufficient to break, as it were, the sleepless habit.

Its influence on the insomnia associated with phthisis I found, on the whole, satisfactory. A night's rest of from six to seven hours frequently resulted from doses varying from 15 gr. to 40 gr. In a girl of eighteen, who had slept but indifferently, 30 gr. induced after thirty-five minutes a nine hours' unbroken sleep, from which she awoke with a clear head and fresh. In two out of the three cases of phthisis in which it was tried there was present, besides moderate insomnia, copious night sweating. The effect in checking this most troublesome and exhausting symptom was marked in both cases. Thus, in a man of forty years of age, who had had profuse night perspiration and indifferent sleep, 30 gr. shortly after his admission gave him the first dry night he had had for some time, besides affording him a fair rest. On the following evening the drug was omitted. He slept very lightly, and was quite wet in the morning. The administration of 40 gr. of chloralamide the evening after gave him an unbroken sleep of nine hours, and he awoke perfectly dry. During the following afternoon he fell asleep for an hour and perspired very much. The efficacy of chloral hydrate in similarly influencing the night sweating of phthisis was pointed out some years ago, I think, by the late Professor Hughes-Bennett. This action is one which has received little or no attention. It is more general than is supposed, and is certainly possessed to a considerable degree by somnifacient agents, and I can fully confirm the statement of Böttrich,[2] that one of the most recent of our hypnotics (sulphonal) is very often an efficient remedy, in doses of from 7 gr. to 10 gr., in checking profuse sweating, whether in phthisis or pyæmia. According to Hagen and Hüfler,[3] chloralamide has in some cases no action on the insomnia of phthisis, while in others it produces considerable general malaise.

The results obtained in two cases of heart disease were encouraging, and would compare favourably with those of any other hypnotic. Doses of thirty grains in a man suffering from aneurysm of the aorta gave fair rest, easing the pain and relieving the cough. There were no disagreeable accompanying effects, the patient bearing the drug well. In a case of emphysema and dilated right heart with orthopnœa 30 gr. had little or no influence; 45 gr. induced slight wandering and a feeling of intoxication, which did not, however, last long. Two nights after 45 gr. were again given, and this time sleep was much more sound, and none of the unpleasant symptoms of the previous evening occurred. Later on 60 gr. were exhibited, producing within twenty minutes a sleep of six hours. Beyond a somnolent tendency during the whole of the day following, no untoward effect was observed. The restlessness and delirium of enteric fever were treated by this drug in two cases. In a strongly built man who had been ill for some time quantities of 30 gr. and 45 gr. produced feelings of sickness and dryness of the mouth on awakening. The amount of sleep obtained, however, was very satisfactory. In a case in an early stage smaller amounts (15 gr. to 30 gr.) materially quieted the delirium and procured a tranquil night. In neither of these two cases was there any influence on the pulse. In a case of Bright's disease where the sleep was seriously

[1] Therapeutische Monatshefte, Heft 8, 1889.

[3] Münchener Medicinische Wochenschrift, No. 30, 1889.

Digitized by Google

disturbed by almost constant headache, for which several remedies had been tried, 45 gr. led, after the space of thirty minutes, to a sleep of eight hours and a half—"the best night's rest he had for many a day." The effects were here tested on alternate evenings. After the third dose (30 gr.) giddiness came on, and the patient, getting out of bed, staggered about the ward as if he were drunk. All next day he felt so heavy and "queer" that he declined to take any more of the substance. Insomnia and restlessness resulting from pain were little, if at all, influenced by chloralamide. In two cases—one suffering from disease of the ankle with starting of the foot at night, and the other from dysentery with cramp-like pain in the abdomen,—doses of 45 gr. caused, indeed, sleep, but which an attack of pain readily broke.

From these few observations it would appear that the new hypnotic is not altogether free from some of the disadvantages attending those already in daily use. Doses of 30 gr. and 45 gr. have been followed by giddiness, feeling of sickness, dryness of the mouth, and even slight delirium—symptoms which, though not alarming, are certainly disagreeable, but which seem to be inseparable from the action of almost all our sleep-producing agents. A comparison of the action of chloral with that of the amide shows that the latter is not so rapid, sleep coming on half an hour to an hour after its administration; whereas after chloral it often results in fifteen minutes. This slight disadvantage, however, is more than compensated for by the almost entire absence of action which chloralamide has on the circulation. Thus Kny[4] has shown that, while the introduction of chloral hydrate into the stomach of a rabbit will produce a fall of 50 mm. to 80 mm. in the blood pressure, chloralamide administered similarly or by intravenous injection does not cause more than 17 mm., a figure which may be reached in normal sleep. This makes the drug an invaluable agent where we have to treat sleeplessness resulting from, or co-existent with, cardiac mischief or other diseases where the circulation is in any way affected. In one of the cases cited above—emphysema and dilated right ventricle—as much as 60 gr. were given with good result, and no bad effect on the heart. Hagemann and Strauss[5] cite three cases of valvular disease where doses of 30 gr. induced tranquil sleep without producing any untoward effect on the pulse; while Reichmann[6] has shown by a series of pulse tracings that chloralamide—in contradistinction to chloral hydrate—is without influence on the circulation. This manifest absence of action is explained by Kny on the supposition that the drug is split up slowly by the free alkali of the blood into chloral hydrate and formamide—the depressing effect of the former on the circulation being counterbalanced by the latter, like all bodies of the NH_2 group, stimulating the vascular centre in the medulla and increasing the blood pressure. Sulphonal, likewise, has very little injurious influence on the heart, but Schwalbe[7] and Ewald,[8] amongst others, have shown that it is of little or no value as a hypnotic agent in insomnia resulting from heart disease, the latter reporting that he "had seen little or no success from the use of sulphonal in the sleeplessness of organic cardiac disease, especially in valvular affection, fatty heart, arterio-sclerosis, emphysema, &c." The dose recommended by von Mering is 45 gr., while, in a recent advertisement by an English firm, the quantity given is as much as 60 gr. These amounts, however, are too large to begin with, more especially if the patient is a female or has been ill for some time. Usually 30 gr. to 45 gr. suffice in the case of a man, while 20 gr. to 30 gr. will give satisfactory results in a woman. In experiments carried out by Alt,[9] 60 gr. produced in two strong healthy women severe giddiness, symptoms of intoxication, with great excitement, and in one great nausea and retching. Chloralamide has no action on the digestive organs, and the appetite remains unimpaired. That this drug will be a valuable addition to our therapeutical armamentarium is undoubted. More extensive observation is, however, required to fix its position more definitely. So far as can be judged from the published reports, we are justified in considering that as a hypnotic it has proved itself efficient, but whether equal to chloral remains as yet doubtful; while its freedom from injurious action and the safety with which it can be administered give it a claim which merits our highest consideration.

AN ANTISEPTIC EVACUATING TROCAR AND CANNULA FOR HEPATIC ABSCESS.

By W. C. BROWN, M.D.

THE surgical treatment of so-called tropical abscess of the liver has until now been confined to the adoption of one of two methods—either to attempt evacuation of the pus by the aspirator, or to cut down on the abscess cavity, lay it freely open, wash it out with an antiseptic and drain. Both methods are faulty in theory and unsatisfactory in result. A cavity in hepatic tissue that has been evacuated by the aspirator cannot heal up without the secretion of more pus in the very act of granulation and contraction, and for one case of hepatic abscess that is successfully treated by this method twenty have to be reaspirated again and again, and the great majority of these have finally to be incised and drained. It may safely be said that when we have a large abscess to deal with, aspiration is utterly useless in itself, and, by the waste of time that it occasions, is, generally speaking, a dangerous procedure. In very small localised abscesses it is probably the best treatment; but these cases are so difficult of diagnosis that they are almost beyond the range of practical surgery; and I find it impossible to endorse the opinion of many surgeons that it does a patient no harm whatever to run an aspirating needle at random here and there through his liver in search of an abscess. Treatment by incision has been more successful and satisfactory, but it also has its drawbacks. One of the principal dangers, and one that has

so far been underrated, is the escape of pus into the peritoneal cavity. A considerable experience of cases of pyæmic hepatitis following dysentery leads me to believe that unless the abscess forms actually on the surface of the liver, there will be no perihepatitis, and consequently no adhesion. Case after case of large abscess of the liver has come to my notice in which there had been no external inflammation whatever, and where the peritoneum was absolutely free. Any incision into liver tissue in instances of this sort must be fraught with the gravest danger. But the most serious complication that surgeons in the tropics have to contend with is the frequency with which the wound becomes septic, in spite of the most careful and repeated washing out of the cavity. The peculiarly absorptive property of hepatic tissue, and the low pyæmic condition of the patient, combine to make this the most fatal complication of an operation which, in itself, is by no means a serious one. With a view to lessen these dangers, and more especially the latter, I have designed an instrument to evacuate the pus antiseptically, and to maintain efficient drainage afterwards until the cavity contracts and closes. Its principal feature is that the cannula continues to act as a drainage-tube, and that by means of a shield in which it slides stiffly it can be shortened daily without removal.

The method of use is as follows:—The existence of pus

Digitized by Google

having been demonstrated by an exploring needle, and the skin having been cleansed, the trocar and cannula, after being soaked in a 1 in 2000 solution of perchloride of mercury, are passed into the abscess; the trocar is then slowly withdrawn so as to allow a stream of pus to follow it and fill the cannula. The long indiarubber tube, which has been previously soaked and filled with the same solution, and which has both its stopcocks closed, is then screwed on to the end of the cannula while the pus is flowing. The cannula is then carefully adjusted to its proper length by means of the sliding shield, which is securely fixed to the side of the patient, a piece of gauze soaked in perchloride solution packed round the cannula, and a light dressing applied. The free end of the tube is then fixed into a receptacle containing perchloride solution and placed at a convenient height by the side of the bed. Both stopcocks are now opened and the pus drains freely into the receptacle. The solution in this ought to be changed frequently, care being taken before removing the tube from the solution to close the lower stopcock. A piece of glass is inserted in the nozzle of the tube, so that it can be seen at a glance if the pus is flowing freely or not. If it is not, suction at the end of the tube will generally overcome the resistance which its own syphon action has not sufficient power to remove. As the diameter of the tube is about a quarter of an inch this will rarely occur, and though a tube of this size will occasionally give rise to some discomfort as the bulging of the side lessens and the ribs become closer, in the great majority of cases it is tolerated without any difficulty. The flow through the tube does not, of course, go on continually, but the syphon action keeps an exhaustive pressure on the cavity, which is sufficient to keep it from being distended with pus, and has a beneficial action in promoting its granulation and contraction. As the cavity lessens in size the cannula is daily shortened in its shield without removal, and the abscess is thus kept quite aseptic until the cannula can be removed altogether. (See preceding figures.)

Messrs. Arnold and Sons, of West Smithfield, London, have taken great pains in the construction of the instrument, and have succeeded in laying before the profession an apparatus which, it is hoped, by its simplicity and effectiveness, will much decrease the difficulties and dangers of an operation for hepatic abscess.

A Mirror OF HOSPITAL PRACTICE, BRITISH AND FOREIGN.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Proœmium.

ST. MARY'S HOSPITAL.

CASES UNDER THE CARE OF DR. BRAXTON HICKS.

THE first of these cases is one in which the excessive loss of blood at the periods was due to a definite local cause, "a localised granulation growth," the origin of which was obscure. That the loss of blood which had been going on was excessive was evidenced by the anæmic condition of the woman when admitted. Without actual inspection of the interior of the uterus after dilatation of the cervix a definite diagnosis could not have been made, in the absence of any history pointing to the occurrence of an abortion; whilst the dilatation gave access to, and permitted removal of, the morbid condition on which the hæmorrhage depended.

CASE 1. *Severe uterine hæmorrhage; removal of granulation growth; cystitis; recovery.*—Mrs. ——, aged forty-six (?), was very anæmic when admitted to hospital, owing to repeated and severe uterine hæmorrhage, mostly at the monthly period. The uterus was found to be bulky, but the os not patent. The os and cervix were dilated by sponge tent, and there was found a rough, granulated surface raised about a quarter of an inch from the surface on the anterior wall, measuring about an inch and a half in diameter. This was scraped by the curette down to the natural level by Dr. M. Handfield Jones, after which perchloride of iron was applied to the surface. There was only slight hæmorrhage during the operation, and none after. Some slight tenderness was felt over the region of the uterus, but in a few days this passed off. But about this time an attack of cystitis came on, and the pain in passing urine produced paroxysms of unusually acute nervous distress, she being of a highly sensitive temperament, which defied very large doses of opiates and other anodynes. After trials of all kinds of sedatives, Dr. Hicks was anxious to have the bladder explored by the cystoscope to see if possibly any extension of disease from the uterus might have taken place, or if an abscess had broken into the bladder. This was carried out by Mr. Page, but nothing could be detected indicating disease or abscess. The peculiar condition found inside the uterus resembled much that of epithelioma, but by the time of this exploration of the bladder, the size of the uterus had become nearly normal, nor was any swelling detected between it and the bladder. With all this negative evidence, Dr. Hicks considered that probably an excoriated condition of the neck of the bladder and the urethra was the cause of the pain. He therefore applied perchloride of iron to the canal, and, after two or three minutes, washed the bladder and urethra out with plenty of water (thus removing the application). Some little distress was felt, but the severity of the pains and the nervous paroxysms were gone, and she continued quickly to improve, leaving the hospital at the end of two months. After the use of the curette there was no sign of blood from the uterus, not even the ordinary period. The granulated surface removed by the curette resembled much that in which an early ovum has been implanted; but there had been no sign of pregnancy, though that would not be proof that an early abortion had not occurred.

Dr. Braxton Hicks[1] has frequently drawn the attention of the profession to the intermittent contractions of the uterus during pregnancy, and the important aid which the observation of these contractions may give in the diagnosis of abdominal tumours, especially those accompanied with amenorrhœa. The short account of Case 2 gives confirmation to the idea that these normal intermittent contractions (coming on commonly every five to twenty minutes) become irregular in character when the patient suffers from chorea; but the contractions do not appear to be more violent.

CASE 2. *Chorea, with irregular action of the normal intermittent contraction of pregnancy.*—A young woman was admitted into the obstetric ward, supposed to be pregnant, suffering from a marked attack of chorea. It appears she had had an attack during childhood, but this had long since passed off. She had menstruated regularly till about four months before admission, and on examining the uterus Mr. A. Hanson, the obstetric officer at that time, found that organ extending nearly to the umbilicus, but soft and natural. On the next day, on examining the abdomen, a firm, hard, pyriform mass was found on the left of the umbilicus, rising rather above it. There was little to be felt of anything like the condition of the day before, but the pyriform mass was prominently to be felt beneath the parietes in the position stated. The next time she was examined, three days afterwards, this firm pyriform mass had vanished and the uterus was of normal shape, but alternating in density during the examination. A few days after this the same variation of density was found, but the form of the uterus changed, one side becoming firm and prominent, while the other was soft and smaller; then the prominent portion relaxed and the other portion became firm. She went out of the hospital, and on her return in a fortnight the uterus was found to have somewhat increased in size, but the irregular action continued, though not to the marked extent as on Dr. Braxton Hicks's first visit in March, 1889.

NORTH LONDON CONSUMPTION HOSPITAL.

A CASE OF PHTHISIS IN WHICH THE FATAL RESULT WAS DUE TO PULMONARY EMBOLISM; REMARKS.

(Under the care of Dr. EVERSHED.)

THIS case is interesting as one in which pulmonary embolism probably caused death by asphyxia. It is a question in the majority of cases of this character whether

[1] THE LANCET, vol. i., 1888, pp. 65, 113.

Digitized by Google

the embolism has proved fatal from syncope or from asphyxia; the symptoms here were more consistent with the latter view, and the extensive disease of the left lung made it probable that for some time it had been almost useless for respiratory purposes. As is well known, a portion of thrombus detached from a vein of the lower extremities is the commonest cause of pulmonary embolism. The conditions favouring the formation of such blood clotting were present in this patient, and the remains of a clot found in the right femoral vein. For the notes of the following case we are indebted to Mr. Moriarty O'Brien, late house physician:—

M. V—— was admitted in July, 1887. She presented the usual appearance of a person suffering from phthisis in its early stages. The account she gave of her family history was very indefinite—that is to say, it was impossible to fix an hereditary taint. She said she was born in London, but had lived on the Continent for the greater part of her life, travelling about, her husband (an Italian) being a valet. Her last abode was Paris, and it was thence she came to the hospital. She had been in good health until twelve months previously to her admission. Her illness began with a slight cold, with cough, &c. The doctor whom she saw in Paris told her that she was suffering from bronchitis. She did not, however, improve under treatment, but gradually got worse, and eventually was admitted into the English hospital in Paris. During her illness she had cough all the time—often very troublesome at night. She had gradually lost flesh, suffered from increasing breathlessness, night sweats, &c. She had always been able to take her food, and never had diarrhœa. Catamenia had been regular. On admission, she was tall, well formed, and stately in her carriage. Her voice seemed natural, but there was occasional huskiness. Her complexion was dark, eyes black and brilliant, skin on exposed parts sallow and bronzed; where covered by clothing, the skin was very fair, and when grasped had a peculiar limp and wet feel. The extremities of the fingers and toes were clubbed, and the lips had a bluish appearance. She became quickly breathless when moving about or exerting herself. Pulse was moderately full, soft, and rapid. On examination of the chest it was found well formed; there was, however, distinct flattening under the clavicles, especially on the left side. There was no expansive movement, the left side seemed almost fixed on causing the patient to inspire deeply; this want of movement was also to be felt; and while the hands were on the chest an increased fremitus was found on the left side. Comparing the percussion notes, a decidedly duller sound was elicited over the left side, and a *bruit de pot fêlé* was heard in the second left interspace. On auscultating, cavernous breathing, with large bubbling râles and pectoriloquy were found over the left apex, with fine crepitations in other parts of this side; the right gave exaggerated breath sounds nearly all over. Nothing abnormal was noticed about the heart sounds. The temperature rose to 102·4° in the evening. The urine had a specific gravity of 1010; there was no albumen. A simple acid mixture was prescribed; the sweats were checked with zinc and belladonna pills, and the temperature reduced with antifebrin.

Under the above treatment, with occasional mild counter-irritation, the patient progressed satisfactorily until the seventh week. There were some slight variations in the weight, but a steady increase on the whole. During the seventh week of her stay there had been some soreness of the throat, with hoarseness and increase of the fever. The parts were seen to be congested. The use of an astringent gargle relieved this, and she recovered her previous good condition, for during the subsequent week—viz., the eighth—she gained two pounds and a half in weight. Early in the following week—the ninth—which was the last week of her stay, she complained of increased dyspnœa. This was aggravated at night. Under the influence of large warm poultices it abated somewhat. Nothing was found in the chest to account for the increased difficulty of breathing. On the following morning the dyspnœa was still marked, and she became suddenly very much worse. She was gasping for breath. No obstruction could be detected in the throat, and air seemed to enter freely. Stimulants were quickly administered, but without result. Within seven minutes from the time she was first seen she was dead.

At the necropsy, made twenty-seven hours after death, on opening the chest the right lung was found non-adherent, and, except for a few tubercles at the apex, seemed free from disease; it was paler than usual. The left lung was adherent all over; it was detached with difficulty from the side. When examined it was found solid and full of tubercles in the lower lobe and simply a multilocular cavity to represent the upper, the tubes containing purulent fluid wherever they remained. The heart was soft and flabby, and, as usual, slightly covered with a soft fat. On opening it, clots were found in all the cavities; the right side was full of a dark clot, which extended to the bifurcation of the pulmonary artery and along the right branch of that vessel, completely blocking it. On breaking through this soft clot a long, branching, and firm worm-shaped clot was found passing along the pulmonary vessel.

Remarks by Mr. O'BRIEN.—Here, then, was the cause of death. The plug existed in the only sound lung. Hence when the vessel was completely blocked death was almost instantaneous. The occurrence of death from this cause in cases of phthisis is not common, though cases have been reported. In this case I believe the clot came from the veins in the right leg, as on opening up the inferior cava some small firm masses were found, and these were also found in the femoral vein.

LINCOLN COUNTY HOSPITAL.

CASE OF EPITHELIOMA OVER UMBILICAL HERNIA; REMOVAL; RECOVERY; REMARKS.

(Under the care of Mr. CANT.)

MALIGNANT GROWTH of the umbilicus, or in its neighbourhood, is somewhat rare, but has been met with both as a primary and secondary affection. When epithelioma affects this part, it usually does so as a primary growth, spreading backwards and rendering it necessary to open the peritoneal cavity in order to thoroughly remove the disease. Thus Desprès[1] found it necessary to remove a part of the peritoneum and subjacent omentum which was invaded in the case of a patient aged sixty-five. Kupper collected eight cases of malignant growth of the umbilicus,[2] and Wulckow[3] and Nélaton[4] have drawn attention to the occasional presence of a scirrhous growth secondary to malignant disease within the abdomen. Nélaton describes this form of growth as frequently resembling that of a collar-stud, presenting expansions externally and on the peritoneal surface. In the following successful case it is probable that the disease resulted in consequence of the irritation of the truss. For the following account we are indebted to Mr. W. H. B. Brook, house surgeon.

H. B——, aged fifty-eight, a widow, was admitted on July 8th, 1889, with umbilical hernia of twenty years' standing, for which she has always worn a truss. She has never had any trouble with it until five months ago, when it became ulcerated. On admission, the patient presented a large flaccid umbilical hernia 9 in. in diameter and pendulous, the tissues over it being extremely thin except where the ulceration was. A little to the right of its centre was a foul cancerous ulcer, 5 in. × 4½ in., oval, with an unhealthy and nodular surface, with everted indurated edges and a hard base. No enlargement of the lumbar or inguinal glands could be detected. On July 17th the new growth was completely removed by a circular incision, half an inch from its margin, through the whole thickness of the hernial sac, commencing at its lower edge. In order to expose as little of the intestines as possible sutures of carbolised silk were put in as the incision was made. The omentum was firmly adherent to, and formed part of, the tumour. The adhesions were ligatured with catgut and divided, a very considerable portion of omentum being removed. The wound, dressed with carbolic gauze under the spray, healed rapidly, leaving only a lined scar, and there was not any material rise of temperature; but the skin over the hernia sloughed a little at the side in consequence of the irritation of the gauze, though this soon healed when dressed with salicylic wool. The patient was discharged on Aug. 26th, there being no return of the growth.

The above case seems interesting from the fact that so large a portion of the abdominal parietes and omentum could be removed under antiseptic precautions with so little reaction, and also the importance of stitching up the wound in such cases, as the tumour is removed, so preventing the escape and exposure of the intestines.

Medical Societies.

ROYAL MEDICAL & CHIRURGICAL SOCIETY.

Presidential Address.—Acute Lead Poisoning.

THE first ordinary meeting of this Society for the present session was held in the new rooms at No. 20, Hanover-square, the President (Sir Edward Sieveking) being in the chair.

The PRESIDENT delivered a short inaugural address, congratulating the Fellows on taking possession of the new premises. He gave some details of the early days of the Society, and traced its history from its foundation in 1805 until the present time. As evidence of the administrative ability of its founders, he instanced the fact that the code of laws they drew up for its management existed practically unaltered at the present time. The first meetings were held in Verulam-buildings, Gray's-inn, and the Society subsequently found a home in three different houses in Lincoln's-inn-fields, moving in 1834 to Berners-street; the first meeting took place there in 1835 and the last on June 11th of the present year. After having referred to the incorporation of the Society by Royal Charter, and to the institution of the Marshall Hall prize, he proceeded to allude to the scheme which had been mooted to amalgamate the various medical societies into one Academy of Medicine. Though he was unable to propose any practical way of bringing this about, yet he thought that there were many questions of a scientific character, to help in the solution of which the various societies might with advantage co-operate.

A vote of thanks was proposed by Dr. Barnes, seconded by Sir Spencer Wells, and carried *nem. con.*

A paper by Dr. THOMAS OLIVER of Newcastle was then read on the Analytical and Clinical Examination of Lead Poisoning in its Acute Manifestations. The author showed the prevalence of poisoning by lead at Newcastle-upon-Tyne, the home of the lead trade. It was more common in women than in men. Of 135 patients admitted into the Newcastle Infirmary, eight died of acute manifestations; of these, five were females. A rapidly increasing anæmia was one of the earliest symptoms, and it was followed by colic, headache, vomiting, and diplopia or defective vision. In a few days the patient might become convulsed, comatose, and die. The illness might be so rapid that no alterations of the viscera could be found after death, other than a hydræmic condition of the brain. The author discussed the cause of the anæmia in lead poisoning, of the defective vision, and of the brain symptoms, and gave the results of analysis of the urine. Though the kidneys were contracted in nearly all chronic cases, gout was practically unknown among the lead workers in Newcastle-upon-Tyne.—Dr. STEPHEN MACKENZIE thought that the experience of most London physicians would correspond with that of Dr. Oliver. At the London Hospital a large number of cases of lead poisoning were treated. Had Dr. Oliver worked out the ratio of men and women affected to the total number employed? Mr. Corner, the medical officer of health for Poplar, had read a paper at the Hunterian Society, giving a description of an attack of acute lead poisoning similar to that described by Dr. Oliver. He had found that the attacks were more frequent in the winter than in the summer, and persons recently employed were more liable. The predisposition not only affected the individual, but occurred in families. The attack in many cases resembled poisoning due to other agents—sometimes it was like alcoholic poisoning. He related the case of a man who had been only a short time employed; when brought to the hospital he was like a drunken man, giving facetious answers; he was then attacked with convulsions, and was found to have double optic neuritis, but under treatment he made a satisfactory recovery. He had seen other cases which ended fatally, the convulsions being followed by coma and death. No albuminuria was present, and at the post-mortem examination no condition was discoverable showing the cause of death, but Mr. Tidy had demonstrated lead in appreciable though small amounts in various organs of the body. As to early symptoms, he thought anæmia was one of the first, and after that vomiting. He had seen also many cases of optic neuritis in which the patients did not complain of defect of sight; other cases had neuro-retinitis. In London it was frequently seen associated with gout. He had seen an attack of acute gout develop in a patient taking lead medicinally. A question of medico-legal importance was how long the lead line lasted after discontinuance of the drug. He related a case in which a patient had been using a hair-wash and developed double optic neuritis, but there was no lead line on his gums. Dr. Gowers had never seen the line disappear in less than a year, but he himself had heard of it going in a shorter time than that.—Dr. ANGEL MONEY inquired into the association of phthisis with lead poisoning; lead seemed to increase the gravity of the prognosis. Women who worked in lead factories aborted frequently, but the products of the abortion were often the subjects of congenital syphilis. He had found that syphilis and lead poisoning together made a combination difficult to treat.—Dr. BUZZARD had had no opportunity of seeing cases of acute lead poisoning. In chronic lead poisoning one got a considerable number of symptoms referable to intracranial lesion. Had Dr. Oliver met with affection of cranial nerves in acute cases? He had known a man with wrist drop to be seized with convulsions, and these to be followed by total paralysis of one oculo-motor nerve; these nerves were usually spared in lead poisoning. He referred to two cases of paralysis of external ocular muscles, but had never heard of a case in which the whole third nerve was paralysed.—Sir JOSEPH FAYRER related a case he had seen in Calcutta, in which a persistent snuff-taker had poisoned himself by the snuff becoming impregnated with the lead in which it was packed.—Dr. FLETCHER LITTLE asked if sulphuric acid lemonade was employed in the works in the north. He had found that it had a most satisfactory effect in preventing the disease. He related an instance in which the vegetable acid contained in water collected from a peat soil acted on the lead pipes conveying it, and had produced several cases of poisoning.—Dr. BARNES remarked on the frequency of abortion happening in those who worked in lead. French observers found that those who lived at home became contaminated by their husbands and aborted. The influence was either exerted on the ovum as in syphilis, or there was direct contamination from the clothes &c. Lead showed a greater predilection for women during the period of active menstrual life.—Dr. OLIVER, in reply, said that the last two cases he observed died in the summer. He agreed that anæmia was one of the first symptoms, and that vomiting occurred earlier than colic. He had seen the blue line disappear from the gums in three or four months. He had not been able to observe any relation between lead and phthisis. A case related by a French physician, of an autopsy on a child whose mother was a worker in lead, bore out the idea that some of these cases were syphilitic, for an intercellular cirrhosis of the liver was found. He had not observed affection of the cranial nerves, though transient diplopia was seen in one case. He thought the poisoning not due directly to the lead, which was usually found in small quantities, but to some proteid material. The lead acted on the blood-making organs, the liver, spleen, and bones, and produced a toxæmia—a true blood poisoning. As to prophylaxis, the difficulty was to make the people follow the regulations laid down, for they would not take the lemonade provided, nor would they wear the respirators or suits of clothes. A free breakfast had materially diminished the cases of poisoning in some of the works. The amount of uric acid secreted was much in excess of the normal, and every now and then analysis showed that there was an explosive elimination of lead; on the days on which this occurred the uric acid fell in quantity. The age at which women were most frequently poisoned was between eighteen and twenty-three; the men, as a rule, were not affected till later.

MEDICAL SOCIETY OF LONDON.

The President's Inaugural Address.—Non-tubercular and Non-cardiac Hæmoptysis of Elderly Persons.

THE first meeting of this Society for the present session took place on Oct. 21st.

The chair was taken by the President (Dr. THEODORE WILLIAMS), who delivered a short inaugural address. He commenced by expressing a hope that the Fellows of the Society would enter on the work of the 117th session with an earnest wish to attempt, and a strong determination to

Digitized by Google

achieve, the solution of some of those numerous problems in medicine and surgery which could assuredly be solved by requisite skill and perseverance on the part of the investigator. He next referred to the satisfactory condition of the Society both as regards membership and finances, and then proceeded to review the papers that had been read during the term of his presidency. Great progress had been made with the library, which was now in working order, and it was hoped that Fellows in the future would use it more freely. The President then alluded to the losses that had been sustained by death, paying a fitting tribute to the memory of each of the deceased Fellows. To conduct the affairs of such a Society, which holds weekly meetings, to secure papers of the high standard demanded, to regulate the supply and prevent deficiency at one period of the session and congestion at another, to enlarge and enrich the discussions by inviting those most learned and experienced to attend and to take part in them; to keep in harmonious working the body corporate, and, above all, to maintain the honour and renown of the Society—these were the aims of the President and secretaries, and in their arduous duties they trusted to receive support from the Fellows at large. He appealed to the younger Fellows especially, in whose hands was the future; they might see the day when the Society, joining with other medical societies, would form an Academy of Medicine, furnished with ample powers and supplied with funds to effectually investigate every form of disease and every means of arresting and of curing it. They might see the day when a rising democracy, whose education had been touched with the leaven of the natural sciences, had learnt to distinguish between the clamour of noisy sentimentalism and the conclusions of science, and to value at their true worth all measures which prevented and destroyed disease, and rendered more healthy and more vigorous the English race. They might see the installation of the Ministry of Health, presided over by a distinguished member of the medical profession with Cabinet rank, who, supported by a now enlightened public opinion, would propose and carry through both Houses of the Legislature measures of preventive medicine, sanctioned by all branches of the medical profession. As old men they might even hope to see the result of all this in the cessation of some forms of disease and in the diminution of others, and then in their turn give place to a race of Fellows of the Medical Society, far more vigorous in mind and body, who would meet together to discuss typhoid fever, small-pox, scarlatina, and hydrophobia with the same historical interest with which we at the present day discussed the plague, the black death, and the sweating sickness. Finally, appealing to the Fellows, Dr. Williams said: "You will do well to remember that the council and secretaries are willing and, I trust, efficient, instruments to carry out your decrees, but that the motive force of the Society must come from yourselves. The life of a society is the life of its fellows co-operating for a common purpose, and its activity or apathy depends on their individual exertions. To you belong the glorious traditions of the Medical Society of London; to you falls the heritage of Lettsom, of Fothergill, and of the immortal Jenner. Show yourselves worthy of these, and leave behind you an example which in turn may inspire future generations."

A vote of thanks having been proposed by Dr. Quain, seconded by Sir Joseph Fayrer, and carried by acclamation,

Sir ANDREW CLARK proceeded to read a paper on the Non-tubercular and Non-cardiac Hæmoptysis of Elderly Persons, which appears in full in another part of our present issue.—Dr. ANGEL MONEY asked if the cases differed in any way from those of arterial degeneration associated with absence of elastic tissue in the lungs. Were they more than cases of emphysema associated with arterial degeneration? Or were they cases of arterio-capillary sclerosis affecting the capillaries of the lung only, and not the rest of the arteries of the body? He was inclined to regard the affection as a part of the general process of arterial degeneration occurring in Bright's disease.—Dr. PERCY KIDD had seen cases of this kind occurring in association with general arterio-sclerosis, granular kidney, or gout. It followed from general physiological laws that slight rises of pressure in the systemic arteries were speedily felt in the pulmonary system. Might not this determine the early local disease in the lung?—Dr. QUAIN was very familiar with such cases, which as a rule did well by removing congestion by calomel, and by forbidding the application of ice to the chest, which latter he had never seen do anything but mischief.—Dr. GILBART SMITH was not familiar with the kind of case described. He had seen instances in which there had been multiple hæmorrhages from various organs, but he had never met with an instance of bleeding from the lungs alone.—Dr. ALLCHIN wondered why the hæmorrhage had been so satisfactorily controlled by treatment; if it were due to progressive degeneration, he thought it would certainly have recurred.—Dr. EWART was inclined to regard the affection as a functional one which occurred only with plethoric emphysema.—The PRESIDENT said that attention had been paid to the state of the blood-vessels, but not to the condition of the blood itself. Might not some of these cases be due to hæmophilia?—Sir ANDREW CLARK, in reply, said he could not regard the disease as an arterio-sclerosis, which was a continuous change throughout the bloodvessels, whereas those he had described were discontinuous; in arterio-sclerosis, again, the change was a fibroid one, whereas in his cases it was nuclear. It might be the form of arterial degeneration which accompanied emphysema, but he thought not; for emphysema was common, but hæmorrhage was rare. Nor did he think it was the change associated with Bright's disease, for no structural change could be found in the kidneys. He thought we should beware of regarding clinical medicine as altogether conterminous with pathology; we should recognise and preserve carefully "clinical individualities." If it could be proved that this hæmorrhage was of a distinct kind, then that was a clinical individuality, and would lead to a different treatment. As to why they did not recur, the patients were usually addicted to over-feeding, imperfect exercise, and there was inadequate evacuation of the excreta; when the hæmorrhage occurred, they became frightened and listened attentively to religious physiological counsel, and after this they walked in the ways of physiological righteousness and did not err in those directions again. The changes found in the blood-vessels of the lungs looked exactly like the changes found in the articulations themselves. He was doubtful (unless in extreme cases of mitral stenosis) whether mere pressure could burst the healthy pulmonary bloodvessels; vascular disintegration must be the initial change. He did not think that there was any suspicion of the hæmorrhagic diathesis. With regard to its difference from endo-arteritis, he admitted that the question was a poser; but though there might be the closest resemblance in structural characters, there might yet be the widest difference in clinical signification. Many different maladies might find common structural expressions.

OPHTHALMOLOGICAL SOCIETY.

Presidential Address.—Pathology of Trachoma.—Keratitis from Paralysis of Fifth Nerve.

THE first ordinary meeting of this Society for the present session was held on Oct. 17th, Dr. Hughlings Jackson, President, being in the chair.

Dr. JACKSON delivered a presidential address, which will be found in another part of our impression.

A vote of thanks having been unanimously accorded to Dr. Hughlings Jackson for his address,

A paper was read by Dr. BRAILEY for Dr. THOMAS REID of Glasgow on the Pathology of Trachoma and the Relation of this Condition to the other Forms of Conjunctival Inflammation. The author regarded the occurrence of groups of lymphoid cells at varying depths in the sub-epithelial layer as the essential part of trachoma. These might be ill defined (lymph heaps) or more distinctly bounded (lymph follicles), though never possessing a perfectly defined limiting capsule. Their lymphoid elements were pervaded and supported by a very delicate stroma. Generally there was some infiltration of lymphoid cells around them which might even extend from one group to the next, and so on. Their origin was not a matter of absolute certainty, but the author was inclined, with Michel, to regard them as the dilated ends of the lymphatics of the conjunctiva. These lymphoid groups led to changes in the epithelial layer, the deeper stratum of which might become vacuolated by œdema, so that the individual cells were often extended into a stellate form. Later, many of the cells might become distended and their nuclei pressed to one side, so that the characteristic appearance of goblet cells was presented. These might discharge their contents, leaving their walls standing and their nuclei

Digitized by Google

attached to their floor, so that, after the throwing off of the condensed superficial epithelial layer, a matter of not uncommon occurrence, the remains of the goblet cells constituted a series of irregular papilliform elevations characteristic of true forms of dry catarrh. Another important change, the development of mucous follicles, might take place in connexion with the goblet cells. When the lymphoid groups, instead of being absorbed, had increased considerably in size, each one, with its covering of altered epithelium, or a small group of them, was apt to constitute a marked elevation of the conjunctiva, separated on each side from its neighbours by a deep depression. The layer of goblet cells occupying these depressions was frequently folded in so as to form a small pouch, which might be much enlarged, so as to constitute a rounded mucous follicle which communicated with a short duct with the conjunctival surface. As above described, these mucous follicles were usually developed between the lymph follicles; but occasionally one and even several small mucous follicles could be seen occupying the centre of a single lymph follicle. Though usually flask-like, they were sometimes more tubular in form, presumably before the discharge of their individual cells, and the consequent accumulation of their contents. Though the lymph heaps or follicles might disappear by absorption, presumably by escape into the lymphatics, they perhaps more often discharged themselves externally by thinning and destruction of the overlying epithelium. There was always to be noted a tendency to softening and degeneration of their central part, as indicated by less definite structure and more feeble capacity for staining. Finally they might, instead of disappearing, become invaded by bloodvessels, and gradually converted into a dense connective tissue, which, situated in the ridge-like or papilliform elevations above alluded to, formed the grey gristly granulations characteristic of the advanced stages of severe trachoma. Careful examinations for bacilli had led to negative results, though the author was disposed to regard the implication of the cornea as a secondary infective process. In follicular conjunctivitis the author found similar lymphoid groups and mucous follicles; also he had determined, by microscopical examinations, that the stage of grey gristly granulations might be reached in the later stages; consequently, he regarded the two affections as essentially one, though he recognised that the vast majority of cases of so-called follicular conjunctivitis might be distinguished clinically from trachoma in that they did not tend to the development of the grey gristly cicatricial tissue. In some advanced cases of purulent ophthalmia he had found lymph follicles, and also in some cases of apparently simple long-standing conjunctival hyperæmia. The essence of purulent and catarrhal conjunctivitis, and also of conjunctival hyperæmia, appeared to be a vascular congestion which might lead to a secondary lymphatic congestion, and the consequent formation of lymph heaps and follicles, whereas trachoma and follicular conjunctivitis were from the outset essentially affections of the lymph follicles. This would account for the occurrence of mixed forms, as in Egyptian ophthalmia, and for the occasional occurrence of one-sided trachoma as a sequence to long-standing conjunctivitis of other forms. In conclusion, the author did not connect the lymph follicles or mucous glands with any of those glandular structures which were rarely found in the normal conjunctiva.—The paper was illustrated by microscopic preparations in the forms of photographs and magic-lantern slides.

The SECRETARY read, for Mr. W. E. CANT, notes of a case of Keratitis from Paralysis of the Fifth Nerve. The patient, a lad aged sixteen, attended at the British Ophthalmic Hospital, Jerusalem, on July 17th, 1888, with complete paralysis of the left fifth nerve. The left eye showed some general injection, and the cornea was diffusely hazy. A history was obtained of an injury by a reaping hook two or three weeks previously, and a doctor who saw the lad two days after the blow had been inflicted found him in a semi-conscious state. There was a small penetrating wound of the squamous portion of the left temporal bone, about an inch above the insertion of the auricle; into this wound a probe could be passed to a depth of rather more than one inch. When seen again on July 22nd, the left cornea was quite opaque, of a milky white colour; there was much general congestion of the eye. He was admitted to the hospital. During the next three weeks the condition of the left cornea became rather worse, and marginal ulceration occurred. The paralysis of the fifth nerve remained complete. The patient then left the hospital, and was not seen again for four months. When he returned the left cornea had partially recovered, but was still generally hazy. The function of the fifth nerve, both muscular and sensory branches, had been regained, but to only a limited degree. Mr. Cant thought the case had been one of direct injury to the whole fifth nerve within the skull, between the brain and the Gasserian ganglion, or at the latter.

The following patients and card specimens were exhibited:—

Mr. LANG: (1) Congenital Coloboma of Iris, with Notch in Lens; (2) Two Cases of Congenital Coloboma of Iris and Choroid; (3) Cystic Formation in Coloboma of Iris.

Mr. QUARRY SILCOCK: (1) Exostosis of Frontal Sinus; (2) Double Proptosis (?) modified Graves's Disease; (3) Probable Sarcomatous Infiltration of Tenon's Capsule.

Dr. ABERCROMBIE and Mr. MARCUS GUNN: A Case of Exophthalmos in a Child with Audible Intracranial Bruit.

Reviews and Notices of Books.

Medical Handbook of Life Assurance. By J. E. POLLOCK, M.D., F.R.C.P., and JAMES CHISHOLM. Pp. 216. London: Cassell and Co. 1889.

THIS book possesses many claims for serious consideration. It is the combined work of a physician who represents three London offices, and of an actuary who has already attracted attention by his writings upon matters connected with the assessment of extra risks. The authors believe that the attainment of greater uniformity of action by assurance companies is much to be desired. Dr. Pollock's views may be taken to represent the practice of the three offices with which he is connected, and they have, presumably, received the approval of his colleague from the actuarial standpoint. Although, according to the title-page, the book is intended for the use of "Medical and other Officers of Companies," the preface widens the scope to include the boards; and later, one chapter at least, that on claims, appears to be addressed mainly to the general practitioner, as it indicates the necessity of care and accuracy in signing death certificates. With regard to the decisions of boards, the authors urge strongly that there should be something like an agreement as to the terms on which lives requiring an addition to the premium should be received. It is of course notorious that, in the struggle for new business, questions of expediency frequently weigh against the report of the medical examiners; but it is equally well known that sometimes an undue timidity of action leads to surprising results, individuals being promptly rejected by one office and accepted with but a moderate addition to the premium by another. Whether such differences are to be attributed to the medical examiners, to the medical advisers, the actuaries, or the board, must always remain a problem. All of these, with the exception perhaps of the first group, have "to appreciate and apply the money value of risks which vary from the healthy standard," hence it must be extremely difficult to attain uniformity of results. Apart, however, from the lack of certainty which is inevitable when proposals pass through so many hands, there can be no doubt that the opinion of the profession has scarcely yet been crystallised sufficiently upon debateable points; indeed, the question of additions to the premium seems still to be in its infancy. Upon prognosis opinions may be very dogmatic, but actuaries demand something more; they look for facts and figures, and in many instances these are still to seek. This the authors distinctly realise, and as cases must frequently arise which cannot be dealt with according to any definite rules, they have collected a hundred typical cases from the practice of certain *unnamed* offices to show how they have been dealt with, and the list has considerable value in indicating both that large extra

Digitized by Google

premiums may be charged, and also are not unfrequently paid. Broadly, it may be stated that, according to the examples here given, the rating appears to be very much on the side of safety. It would be most interesting, however, to know at some future date the further history of these cases. As it stands at present, this abstract would seem to show that no case can be too bad for consideration, and for its assessment at some price; it may tend to make medical examiners hesitate to recommend that a proposal should be declined, but it is scarcely likely to change the practice of those familiar with the intricacies of extra rating.

The book opens with three chapters respectively devoted to an explanation of the nature of life assurance, of the duties of the chief medical adviser, and of the medical examiner, and these are followed by the more purely medical questions connected with the method of dealing with the various deviations from the healthy standard. It is here that many practitioners will find many useful hints. The authors guard themselves carefully against the risk of becoming too diffuse; bearing in mind that the book is intended as a handbook for occasional reference upon knotty points, they preserve a dignified brevity which presents answers to most questions, while it does not trouble with useless information. They assume that the medical men into whose hands the book may fall are already fully acquainted with the purely technical branch of medicine, and merely require information upon the importance to be attached to abnormal conditions of the heart, lungs, &c., from the life office point of view. Questions of age, of occupation, of obesity, and leanness, receive due attention, and in an appendix space is found for extracts from Dr. William Ogle's valuable Supplement to the Forty-fifth Annual Report of the Registrar-General of Births, Deaths, and Marriages in England. The different forms of medical examiner's report might with advantage have been omitted. The authors can scarcely suppose that the authorities at the offices are unaware of the details in which their reports differ from those employed elsewhere. On the other hand, the medical examiners are required to fill in the reports supplied to them by the office for which they are acting, and will always find these sufficiently irksome without wishing to compare them with any ideal standards.

In spite of the minor points to which exception has been taken, and of some very obvious printer's errors which will be sure to be removed in later editions, the authors are to be congratulated upon having produced a book which from its completeness, brevity, and trustworthiness is admirably adapted for general employment and frequent reference.

The Science and Practice of Midwifery. By W. S. PLAYFAIR, M.D., F.R.C.P. Seventh Edition. London: Smith, Elder, and Co.

THE fact that this work has reached a seventh edition is alone sufficient to show that it meets a want, and that it enjoys considerable popularity with the student. The present edition differs but little from its predecessor. The chief change is the introduction of the obstetric nomenclature decided on by a committee appointed at the International Medical Congress held at Washington in 1887. Several new woodcuts have been added, and greater emphasis has been placed on defective sanitation as a cause of puerperal fever. There are some points, especially in the chapters dealing with the diseases of pregnancy and the puerperal state, which require revision. The author states that spontaneous ascent of the retroverted gravid uterus is quite exceptional. This statement is too sweeping; retroversion is by no means uncommon, while permanent incarceration is comparatively rare. Again, jaundice is spoken of as the result of acute yellow atrophy. This is true of a minority only of the cases of icterus in pregnant women. Careful examination of the placenta and membranes after labour is not insisted upon, and the methods of ascertaining that portions are left behind are not described. With regard to puerperal septicæmia, we read: "The most practical division of the subject is into cases in which the septic matter originates within the patient, so that she infects herself, the disease being then *autogenetic;* and into those in which the septic matter is conveyed from without and brought into contact with absorbing surfaces in the generative tract, the disease being then *heterogenetic.*" This division is far from being universally accepted by obstetricians. The retention of portions of placenta or membranes, and severe injuries to the genital tract, are not necessarily followed by septicæmia, and the opinion is largely held that the decomposition which takes place in these tissues is the result of the introduction of something from without, and unless that something be itself septic, septicæmia does not follow. The results of the use of antiseptics in midwifery go far to uphold this view. Dr. Playfair believes that the poison of the acute zymotic diseases, and especially that of scarlet fever, can produce puerperal septicæmia. Some evidence in support of this view is given, but the whole of the evidence against it, and in favour of the view that scarlet fever "breeds true," which has been published both in this country and in Germany during the last two years, is omitted. Much stress is laid upon the part played by sewer gas in causing puerperal disease, and there can be no doubt of its efficiency in this respect. To place this matter in a proper light, however, much work has yet to be done, and it has to be done, too, under peculiar difficulties, for these cases occur in private dwellings, and it is almost impossible in such cases to eliminate other sources of infection.

OUR LIBRARY TABLE.

The Rotifera or Wheel Animalcules. By C. T. HUDSON, LL.D., assisted by P. H. GOSSE, F.R.S. Supplement and Plates xxxi.-xxxiv. Pp. 64. Longmans. 1889.—The excellent volume on the Rotifera published by the authors in 1886 had only one defect—it dealt exclusively with the British species of Rotifera, though these, as might be anticipated from their minuteness, are easily wafted from place to place, and are as a rule commonly found in other parts of the world. The valuable supplement now published, though thin and small, contains descriptions of all the known foreign species (amounting to about ninety), and upwards of sixty British species which have in the course of the last three years been discovered by Mr. Gosse, the whole making a total of 150 species. Nearly every one of these is figured in the plates which accompany the part. A large bibliography has been added, giving the names of the authors of upwards of 200 works devoted to the consideration of these tiny specks. Mr. Hudson in his preface feelingly bewails the loss of his friend and coadjutor Mr. Gosse, whose numerous and lively memoirs on natural history must be familiar to all lovers of the subject.

Cremation and Urn Burial, or the Cemeteries of the Future. By W. ROBINSON. London, Paris, New York, and Melbourne: Cassell and Co., Limited. 1889.—In this treatise the comparative merits of cremation and burial are once more discussed with considerable fulness. It is not remarkable that the author, a strong advocate of urn burial, should use every effort in order to prove his case, and that the leading argument throughout the book should consist of a catalogue of abuses prevalent under the present system of interment. The desecration and the risk implied in disturbing graves for purposes of reinterment, the grossly insanitary state of many graveyards and cemeteries from

Digitized by Google

overcrowding, imperfect drainage, or shallow burial, and their influence as causes of offence and illness, are described at some length and illustrated by striking examples. Some of these, indeed, refer to recent occurrences, but it is worth noting that many more are taken from accounts of the heedless practice of past times, and of countries notoriously wanting in regard for hygienic rules. Probably too much is made of the well-known tendency of putrid gases and matters to percolate the liquid soil. It certainly seems to us that the objection urged against the earth-to-earth system on this ground is overstated. There is more weight in the suggestion that much of the land now used for burials might, under another system, be saved for purposes of cultivation. The latter half of the book is occupied with a history of the cremation movement in this country, and with various practical details bearing upon the subject. The work, as a whole, is at once instructive, light, and readable, and will repay careful perusal.

Medical Guide to the Mineral Waters of Royat (Auvergne). By Dr. C. A. PETIT. Pp. 101. London: Renshaw. 1890.—This work gives a fair description of Royat and its bath establishments, apparently more intended for the general than the professional reader. It has the usual failing of these guide-books—that while it enumerates a legion of diseases in which the waters are said to be beneficial, it leaves unnoticed those in which they are likely to prove useless, if not injurious. The medical summary, occupying the last three pages, does not convey much instructive information.

Lavori dei Congressi di Medicina Interna. Publicazione fatta per mandato del comitato ordinatore del Prof. Edoardo Maragliano. Antica casa editrice Dottor Francesco Vallardi, Milano.—This volume is the official report of the proceedings of the first Italian Congress of Internal Medicine, which was held in Rome in October, 1888. It gives the regulations of the Congress and the text of the various papers read at it, and some account of the discussion upon each. Some of the most important of these were mentioned at the time in the columns of THE LANCET.

New Inventions.

LEGGING FOR VARICOSE VEINS.

THIS is an appliance, patented, for the treatment of varicose veins of the leg, and consists of a plate of felt over the inner half, and of a canvas pliable part attached to it and completing the remainder of the circumference. It is secured by means of straps and buckles. The fine felt plate is moulded to the shape of the leg, and slightly stiffened over the course of the veins. Should it not fit comfortably, it is only necessary to hold the felt in front of the fire, which will soften it; after having been moulded it will retain its shape if allowed to cool. "It acts rather as a leveller than by pressure." It is calculated to wear for two years, and may be washed when necessary. This legging is likely to prove useful in the treatment of many cases of varicose veins of the leg. It is manufactured by Mr. Strudwick of Upper Marylebone-street, at the suggestion of Dr. Fisher.

PATENT BANDAGE PIN.

MR. GEORGE GOODMAN, of 82, Caroline-street, Birmingham, has forwarded us a specimen of his patent nickel-silver bandage pin. For this he claims the following advantages: That it is perfectly safe in use, having its two points thoroughly protected; that it is the only pin that can be depended upon to retain its exact position and thus preserve the exact amount of pressure desired; that it has a flat and smooth surface which cannot cause any inconvenience to the wearer or become entangled in the material; that it is practically non-corrosive even in contact with chemicals and moisture. There are two objections, however, which may prevent the extensive use of this pin; these are, the fact that the points tend to diverge or converge when being passed through soft material, and they are more expensive than the safety pins in ordinary use.

SPLINT FOR FOOT-DROP.

I HAVE devised a new Elevating Spring for Foot-drop due to paralysis of the anterior tibial muscles, whether occurring in infantile paralysis or in the paralysis of adults. It consists of a curved rod (B, C) of well-tempered steel, moulded to the posterior outline of the leg below the knee, and more convex posteriorly than indicated in the figure. The upper end (B) of the spring fits a socket in an ordinary transverse leather band (A), buckled round the calf, while the lower end (C) fits a hole in the back of the heel of the boot, where it may either be a permanent fixture or made to extend to a spring catch (D) in front of the heel. A steel plate is embedded in the sole to prevent the latter yielding to the weight of the foot. The spring should form, when not being worn, a more acute angle with the sole of the boot than is shown in the illustration, and its strength should be sufficient to keep the patient's foot at a right angle or less with the leg while walking. The following are the advantages claimed for this splint:—1. First and foremost, its simplicity and durability as compared with the constant renewing of elastic tractors and the frequent breakage of complicated steel springs for foot-drop. 2. Its sightliness; from the spring being placed behind the leg, it is scarcely noticed when worn. 3. Its comfort to the patient in being very light and in not catching the dress, as is the case with other foot-drop splints where the spring is attached to one side of the leg. 4. Lastly, and not its least advantage, is its cheapness. I have employed this instrument for the last two years with gratifying results. It is not only very efficient in children, but it enables adults affected with hemiplegia or paraplegia, who are beginning to walk again, to do so without the toes dragging the ground, and without the leg being forced to describe a semi-circumduction at the hip with each step, which is so distressing to witness. With this splint applied, the foot and leg can be carried directly forwards, to the great comfort of the patient, and with much less fatigue. I have to thank Messrs. Mayer and Meltzer, of Great Portland-street, W., for carrying out my ideas in the designing of this efficient little instrument.

BERNARD ROTH, F.R.C.S.

Queen Anne-street, Cavendish-sq., W., Sept. 27th, 1889.

PROVINCIAL SUNDAY AND SATURDAY HOSPITAL COLLECTIONS.—The recent Hospital Sunday and Saturday collections at Basingstoke, on behalf of the Cottage Hospital, Basingstoke, produced, net, £33 15*s.* 8*d.* The first Hospital Sunday collection at Yorktown, Surrey, held on the 13th inst., realised £9 18*s.* 8*d.*, which is to be divided between the Royal Berkshire Hospital, and the Herbert Convalescent Home, Eastbourne.—The Hospital Saturday collection at Newbury, on the 10th inst., amounted to £70 11*s.* 5*d.*, of which ten guineas have been sent to the Newbury Dispensary, three guineas to the Speen Convalescent Home, and £56 18*s.* 5*d.* to the Newbury District Hospital.—The Hitchin Hospital Sunday demonstration, on the 6th inst., on behalf of the Herts Convalescent Home, produced £8.—The Wisbech Hospital Sunday collection, on the 6th inst., for the North Cambs Hospital, amounted to £8 10*s.* 10*d.*

Digitized by Google

THE LANCET.

LONDON: SATURDAY, OCTOBER 26, 1889.

ON Oct. 31st the Infectious Diseases Notification Act comes into operation. This is a matter of high interest to general practitioners in the metropolis. In other parts of England, Ireland, or Scotland the Act may or may not be adopted. But it takes effect at once, after Oct. 30th, in every London district, which is defined in the Act to mean the City of London, or the parish or district mentioned in Schedule B of the Metropolis Management Act, 1855, for which a local authority is elected. We say it is a matter affecting general practitioners. But is it quite certain that they alone are affected? Doubtless they are chiefly aimed at, and it is they who are expected to give life and effect to this important Act. But Clause 3 says that "*every medical practitioner*" attending on or called in to visit the patient shall forthwith send a certificate, with particulars of the name and patient. We apprehend that Mr. RITCHIE will not be too exacting, and that if he gets a certificate from one medical man in attendance he will not care for more, though he has actually enacted that "every practitioner attending or called in" shall certify.

We should advise every medical practitioner to procure a copy of this Act, to study it for himself, and to accept the duties of it heartily. It is of no use now to kick against the pricks; neither can we see, if the Act must be enforced, why it should not be enforced everywhere. In this locomotive age one place is at the mercy of another, and precautions and restrictions which are exacted in one place should be exacted universally. The public health is not to be secured by laws of partial application, and this is eminently an Act that, if applied at all, should be applied everywhere. The first duty of a medical practitioner which seems to arise out of the new Act is to apply to the local authority of his district for forms of certificate. On the occurrence of any case contemplated in the Act or in any future order of any local authority—for power is given to such authorities, with the sanction of the Local Government Board, to extend the definition and range of infectious diseases to be notified—the medical attendant, as soon as he has satisfied himself of its true nature, is to forward to the medical officer of health for the district a certificate stating not only the nature of the disease, but the patient's name, the situation of his house, &c.

It is interesting to mark the diseases in regard to which the Act requires notification — viz., small-pox, cholera, diphtheria, membranous croup, erysipelas, the disease known as scarlatina or scarlet fever, and the fevers known by any of the following names: typhus, typhoid or enteric, relapsing, continued, or puerperal. The most noticeable omission from this list is that of *measles*. The omission is noted by the clerk of the Metropolitan Asylums' Board, who says that his Board has on several occasions been asked to receive measles for isolation. It would certainly be a great advantage to know the first cases of a measles storm. It might not be so easy to isolate and circumscribe the first cases of measles as of scarlet fever, but the information should be forthcoming. It is of no use doing notification by halves. If it is to be done for the other diseases we have mentioned, it should be made to include measles. The disease is a serious one; it is highly infectious; it has recently assumed the proportions of a fatal epidemic; it disorders the course of education perhaps more than any other disease, and it is one that should clearly be notified. The only other disease whose presence in this list we feel disposed to notice is that of puerperal fever. What is puerperal fever? The Local Government Board should be prepared to give a definition of puerperal fever for the guidance of practitioners? Surely every puerperal patient that has a high temperature is not to be reported to the medical officer of health. Every obstetric physician will recognise that lying-in women are liable to pyrexia which implies no infection and is not of a septic character, and which it would be absurd to notify. The inclusion of puerperal fever cases adds to the difficulty of medical duty under this Act, and it will be a fine point to determine what is to be considered a case within the meaning of the Act. The point will have to be decided conscientiously for himself by every practitioner after a due consideration of all the facts and symptoms of a case.

Speaking generally, the most important suggestion that we can make to our readers as to their duties under this Act is to approach these duties without prejudice, and especially without haste. The Act requires them to certify to the medical officer of health. But they must first certify the cases to themselves. They owe much to the law, but they owe more to their patients; and when so much turns on a right diagnosis of disease, the first duty is to see that this is decided and deliberate. The duty of notification is second to the duty of diagnosis. Nothing in law or reason can excuse haste of diagnosis when it involves notification, and possibly a demand for isolation and removal. Diagnosis is very easy to those who know very little about it; but early diagnosis of the diseases in Clause 6 of this Act is by no means always easy. How insidious typhoid may be for a week or even a fortnight. In a cholera epidemic how fine the dividing line between a bad diarrhœa and the true disease. In times of sore throat it is not always possible to say when diphtheria begins and follicular tonsillitis ends. The early diagnosis of scarlet fever is a nice duty for an experienced practitioner, and even small-pox takes us occasionally by surprise. The great point for our readers is not to certify till the case is clear, and they are fully persuaded in their own minds of the accuracy of their diagnosis. As soon as they are satisfied of the nature of the case, it is their duty to notify, but not an hour before. Having certified the infectious character of a case, it will be well to consider the means of isolation possible in the dwelling of the patient, and to advise him accordingly, not forgetting that the patient is the first care of his medical attendant. We shall all do wisely to give more heed to early and accurate diagnosis; and our educational authorities will do well to hasten such improvements in medical education as will facilitate medical duty to the patient and to the State; the more so as Mr. RITCHIE has procured, at the request of the

Medical Council and College of Physicians, legislation that makes the Hospitals of the Metropolitan Asylums' Board available for purposes of medical instruction.

THE annual commemoration at the Royal College of Physicians of the most illustrious name upon its long roll of Fellows, which took place on St. Luke's Day before a distinguished audience, was entrusted this year to a physician whose polished style (so well known by his work on "Prognosis in Consumption") gave promise that the customary tribute would be gracefully rendered. Nor could his hearers have been disappointed with Dr. POLLOCK'S efforts in this respect, for he presented them with a vivid picture of the conditions under which HARVEY laboured, and the fruits that have been reaped from his discovery of the circulation. It is a well-worn topic, and needs all the art of an orator to present it in a fresh light. For the life of HARVEY is so simple in its details, and his methods of research are so precise and guarded in their exposition, that no one can fail to honour the man who did so much, by example and precept, to open up the path of scientific inquiry. The same story has been told every year in the College for upwards of two centuries, and yet it still bears the re-telling, for the lessons it conveys are imperishable. Their main theme is that of unfolding the secrets of nature by the method laid down by BACON—a method which HARVEY was almost the first to employ,—and in so doing to break away from the traditions of the schools and to liberate free inquiry from the thraldom of superstition. In order, indeed, to realise the magnitude of HARVEY'S work we must, as Dr. POLLOCK was careful to show, understand the conditions under which the student of science laboured in his day. It was a time when the most powerful church in Christendom was already beginning to receive a check. There is no need to attack the Church of Rome on the ground of its special tenets, or its claims to infallibility; but at the same time it can never be forgotten that in its determined opposition to the promulgation of new truth it is largely responsible for the slow progress made in the observation and interpretation of natural phenomena. In spite of all its efforts, however, scientific truths came to be revealed; and it seems almost as if, in the present day, the attitude once taken by the Church towards Science was in danger of being assumed by the latter herself. "Dogmatism," said the Harveian Orator, "is the tyranny of power over mind, of system over independent judgment"; and up to HARVEY'S time "all teaching hitherto had been dogmatic." Now, however, when, thanks to HARVEY and the labours of all the scientists that have followed him, science has gained a firm footing, is there not some risk lest the dogmatism of which Dr. POLLOCK spoke should be exercised in the name of science, with almost as much injury to freedom of thought and inquiry in ultra-scientific departments as had ever been inflicted by the dogmatism of religion upon scientific truth? It is well, therefore, to be reminded, as Dr. POLLOCK did remind us, in a later passage, that the truths revealed by science are not the only truths, and that we cannot by searching find out GOD. One other declaration before leaving this subject ought in justice to be made. It is not the province of the follower of science to judge of the motives that swayed religious bodies in their too successful attempts to stifle free inquiry or to impose on men a limit to their faith. The man of science has enough to do in searching out the secrets of nature without entangling himself in the meshes of theological controversy. So far from there being antagonism between the two provinces of human thought, there should, since there is no ground common to both, be perfect liberty to the votaries of each to pursue their own road in promulgating their own special truths without reference to the other.

HARVEY'S life is an illustration of this view, for he was filled with the religious spirit, and did all his work reverently, seeing GOD in nature wherever he penetrated to new facts. As to his great discovery itself, he would cheerfully have acknowledged his indebtedness to the eminent Italian masters in anatomy, to whom, indeed, some notion of the circulation seems to have been present. In our admiration of HARVEY, we are sometimes prone to claim more for him than he would ever have claimed for himself. But, at least, he crowned the edifice; he demonstrated "by experiment" the action of the heart and the flow of the blood stream into and from its chambers, although it was reserved for MALPIGHI to demonstrate the existence of capillary circulation. Dr. POLLOCK sketched briefly the results that have flowed from HARVEY'S discovery, and the subsequent explanation of the function of respiration through that other "epoch-making" discovery of oxygen by PRIESTLEY and LAVOISIER. These facts form the basis of all modern physiology, and therefore of pathology. With this increase of knowledge, has there been a commensurate gain in happiness and health? To this Dr. POLLOCK replied by referring to the decline in mortality in this country from such diseases as phthisis and the zymotic class; but he also pointed out that the wear and tear of modern civilisation is bringing in its train evils which go far to counterbalance the good thereby attained. The oration concluded by a happy reference to the fact that the strain of all this high-pressure existence falls upon the heart, and that therefore we should apply the knowledge first given us by HARVEY to mitigate the evils thus induced. The warning is needed, and the moral is clear.

WHEN the Contagious Diseases Acts were suspended as to the compulsory examination of women in 1883, and repealed entirely somewhat later, it was resolved, in accordance with precedence, that they should also be repealed in all those colonies where they had been enforced. This has been done, with we believe one or two exceptions, and sufficient time has elapsed to enable us to compare the results of the working of the Acts with those which have followed their repeal. These latter have been so disastrous in India and in Singapore that men in high positions have felt compelled to speak plainly about it. One of these is Sir FREDERICK ROBERTS, who, quoting a statement made to him by the Surgeon-General, remarked that the number of cases of venereal disease in the army had doubled since the repeal of the Acts, and that the nature of the disease had greatly increased in virulence. It was, he observed, hopeless to expect to put down the

Digitized by Google

evil altogether; all that could be done was to minimise its bad results, and institutes were now being established everywhere for the purpose of trying to keep the soldier out of the way of temptation by providing him with rational amusement and education. His Excellency the Viceroy observed that the Government of India was much indebted to the Commander-in-Chief for his weighty and outspoken statement. Any doubt which might have been felt as to the gravity of the case must have been dispelled by that statement. He advocated the exclusion from camps of women known to be infected, and the provision of hospitals in which they might be adequately treated. He agreed with General CHESNEY that to say that such steps ought not to be taken was tantamount to claiming for a class of diseases, which are probably attended with more disastrous consequences than any other, both in their immediate and remote effects, an immunity which is not claimed for other kinds of contagious maladies. "I do not believe," he said in conclusion, "that such an immunity will be claimed even by those who are most earnestly desirous of discouraging immorality, and I hope public opinion will support us in the reasonable steps which it will be our duty to take in order to carry out within the limits which I have indicated this most necessary measure."

In Singapore there has been even plainer speaking, its insular position making it peculiarly liable to the importation and propagation of these diseases, and Major MCCALLUM, of the Insular Municipal Commission, described the repeal of the Contagious Diseases Acts as "the most cruel and inhuman step ever taken out here." It was unanimously resolved "that a committee be appointed to collect statistics and information relative to the effects of the repeal of the Contagious Diseases Ordinance, with a view to a report being framed and forwarded to Government, by which clauses may be introduced in the Municipal Amending Ordinance under which the practice of prostitution in Singapore may be regulated." A memorial signed by all the medical practitioners among the civil population—Messrs. GALLOWAY, JANSZ, KOEHN, LEASK, and TRIPP—has been presented to the Municipal Commission. It points out the great and increasing injury to the public health that has been inflicted by the abolition of the Contagious Diseases Ordinance, and the consequent withdrawal of all checks to the spread of venereal diseases. It also deplores the virulent type of the disease, and predicts results of the most baneful description, to which it is impossible to see any limit. It applauds the proposed interference of the municipality, and indicates the special causes which make Singapore exposed to these diseases. These are: (1) The preponderance of males among the Chinese who are without domestic relations; (2) the large shipping trade touching at Singapore, including troopships and men-of-war of various nationalities; and (3) the residence of a considerable garrison. To these were added a female population disproportionately small to an unparalleled extent, and the absence of any proper supervision over or check upon the conditions that are producing this constant increase in venereal disease. This memorial, which is extremely well worded throughout, concludes by the statement that in the professional opinion of the memorialists some remedy must be found by those who are responsible for the health of the community. The memorialists also desire to put on record their united protest as professional medical men, responsible to a great extent for the health of the civil population, against the existence of a disgraceful and dangerous state of things, due in great measure to the enforced withdrawal, against the wish of the community, of a legislation that was completely justified by facts, by disease statistics, and by professional opinion and experience. The army, naval, and colonial surgeons, though debarred by their official positions from signing the memorial, expressed perfect approval of it.

THE difficulties surrounding the University of London in its attempts to draw up a scheme to meet the requirements of the Royal Commissioners, to which we adverted in a recent issue, were emphasised most strongly at two meetings held in Birmingham on the 12th inst., and in a letter from Sir J. SAWYER to the *Birmingham Daily Gazette* on the following day. At the conference of the representatives of the provincial University Colleges of England and Wales, held at Mason College, delegates from nearly all the University Colleges were present except from those affiliated to Victoria University, and this important resolution was unanimously adopted:—

"That this meeting, composed of representatives of the University Colleges at Aberystwith, Bangor, Birmingham, Cardiff, Leeds, Newcastle-on-Tyne, Nottingham, and Sheffield, protests strongly against the adoption of any scheme for remodelling the existing University of London which follows the lines of the report of the Royal Commission, on the ground that any such scheme invades the vested rights of the provincial colleges, and, by placing them at a disadvantage as compared with the metropolitan colleges, would, if carried into effect, operate seriously against their future progress and development."

A small committee was appointed to arrange for a deputation to the Lord President of the Council, should he be willing to receive it, in support of this view. The provincial colleges evidently do not intend the "indispensable" condition laid down by the Royal Commissioners for the formation of a Teaching University of London—namely, that its teaching institutions ought to be in or near London—to be acted upon by the existing university if they can prevent it. They still believe that direct association with the latter university would give metropolitan colleges "a position of preference, both in dignity and influence," and they will therefore strenuously oppose any scheme embodying this principle. It was on this rock that the first scheme of reform presented to Convocation by Lord Justice FRY'S Committee was wrecked, and it seems as if a similar fate is to be anticipated for any other proposal on similar lines. Yet if the University of London is to undertake the functions and duties of a Teaching University for London in compliance with the suggestions laid down in the Royal Commissioners' report, this limitation of direct powers to the metropolitan colleges must be unequivocally asserted in any proposed charter of reconstitution. The Commissioners say that "it is sufficient for bodies outside London to have access as heretofore to examination and degrees." A university giving powers to such institutions would not be what is wanted; it would not be a "Teaching

Digitized by Google

University in and for London." The differences in position between the London and the provincial colleges in a reconstituted university could not be more explicitly pointed out.

The difficulty in maintaining the present standard of the medical degrees in the University of London, whilst satisfying the demands of those who ask legitimately enough for a degree as a reward for students who have honestly gone through a fair curriculum and have passed a satisfactory examination, was referred to at the meeting of the governors of Queen's College, and was regarded as insuperable. Professor TAIT, Mr. MATTHEWS, the Home Secretary (who was present as a governor of the College, but who is also a member of the Senate of the University of London), and Sir J. SAWYER, all deprecated the lowering of the quality and the value of the London degrees, and looked upon them as special distinctions. But, whilst the Professors in Arts and Science were considering a Midland University as a probable realisation of their hopes in the future, the medical authorities were urging an affiliation with a university of less "examinational stringency" than the University of London, such as the University of Durham, as a complete remedy for their present grievances. Affiliation with the University of London is a thing of the past—although Sir J. SAWYER writes as if it still existed in the case of Queen's College—and meant nothing and was valueless even when it had a nominal existence. Affiliation with the University of Durham means a substantial advantage, and in the case of a medical student the practical boon of an exemption from a year's medical attendance and study now compulsory at the Newcastle School of Medicine. If Birmingham students are to have this privilege by affiliation of Queen's College to the University of Durham, we should recommend the authorities of the London colleges and medical schools to apply for a similar privilege, if degrees cannot be obtained for their students on fair terms in the metropolis. If any non-resident students are to have the privileges offered to them which are now in the possession only of those educated at Newcastle-on-Tyne, surely London students, whose clinical opportunities are acknowledged to be unique, would have the first claim. A Teaching University in London and a Teaching University in the Midlands on the lines of the Scotch Universities would solve the difficulties in a more satisfactory manner than such remote and unreal affiliation.

Annotations.

"Ne quid nimis."

ST. LUKE'S DAY AT THE COLLEGE OF PHYSICIANS.

THE Harveian Oration, which was delivered by Dr. James E. Pollock on the 18th inst., was attended by a large number of the Fellows and Members, and some distinguished visitors, including Mr. Justice Denman, Canon Duckworth, Cardinal Manning, and Count Leyden. On the conclusion of the oration, the President, Sir Andrew Clark, Bart., presented the Baly Medal to Professor R. Heidenhain of Breslau, stating, in well-chosen terms, the grounds upon which the medal had been bestowed. The medal was, in the absence of Professor Heidenhain, received by Count Leyden, who expressed, on behalf of the recipient, his acknowledgment of the honour. In the evening about eighty Fellows assembled at the Harveian dinner, which took place in the College. The President was supported by the Archbishop of Canterbury, Mr. Ritchie, M.P., President of the Local Government Board; Mr. Justice Denman, Dr. Peel Ritchie, President of the Edinburgh College of Physicians; Mr. Makins, Master of the Society of Apothecaries; the Rev. Dr. Troutbeck; the Vice-Presidents of the College, and other officers. The President gave "the health of the Queen," and Dr. Quain that of "the Guests," which was responded to by the Archbishop of Canterbury and Mr. Ritchie. Dr. Bristowe proposed "the health of the Harveian Orator." The company afterwards adjourned to the library.

SOME RESULTS OF COMPULSORY NOTIFICATION.

DR. CAMPBELL MUNRO, in recording the death-rate of the Jarrow urban district during 1888 as 17·1 per 1000 living—this being the smallest rate since 1871, when it was 34·7 per 1000—takes occasion to refer to the operation in Jarrow of the compulsory notification of infectious diseases, and for this purpose he contrasts the periods 1871–78 and 1879–88. In the former, when no such system was in force in the borough, the mean death-rate from all causes was 25·2 per 1000; during the second period, when notification was in force, it was 20·8, representing a decrease of 17 per cent. Continuing the analysis as regards the seven principal zymotic diseases as a group, the second period is found to show a decrease of 45 per cent. when compared with the former. And, coming next to individual diseases, he explains that the local Act of 1878 required the notification of small-pox, of the various fevers, and also of cholera, no cases of which occurred during either period. As to small-pox, the rate during the earlier period was 15·31 per 1000, and 0·36 in the second, giving a decrease of 97 per cent. The mean death-rate from scarlet fever in the first period was 17·87; in the second it was 6·72, a decrease of 62 per cent. The mean death-rate for the continued fevers was 7·81 in the first period, as compared with 2·65 in the second, giving a decrease of 66 per cent. And summing up, the decrease in the fatality of the notifiable diseases shown during the second period was 99 per cent. of the total decrease in the zymotic mortality. Diphtheria and measles, which are not notifiable in Jarrow, had unfortunately exhibited an increase during the second period. We imagine that Dr. Munro would be the first to admit that the whole of the remarkable diminution in death to which he refers has not been due to the system of compulsory notification in force during the second period adverted to. Thus, whilst granting, in the case of small-pox, the extreme value of notification as a means to the early isolation of the disease, and the much greater risk to which the community would have been subjected had small-pox cases not been immediately heard of; yet it is well known that whereas this disease was generally rife in the country during the earlier of the two periods, there was no general diffusion of it during the second period; also, with regard to enteric fever, many of the important improvements effected in Jarrow during the last ten years must have materially aided in diminishing the spread of this disease. And, further, diarrhœa and whooping-cough, neither of which is notifiable, have also exhibited a decrease during the last ten years. But, apart from these and other allied considerations, Dr. Munro is obviously justified in making a substantial claim for the system he adverts to, and the descriptions he has given of the uses to which the information acquired by notification is put in his borough prove

Digitized by Google

how largely immediate measures of prevention have in various ways been applied to the diseases under consideration. Dr. Munro, indeed, claims that the results he has shown form an enduring memorial to the foresight and public spirit of those who, when compulsory notification was but a new idea, were not afraid to adopt the system; whilst they also afford proof of the loyalty of the medical profession who, throwing aside all personal considerations, have acted throughout solely for the benefit of their fellow townspeople.

MEAN DURATION OF LIFE IN LONDON.

DR. CORFIELD, in his report on the sanitary condition of the district of St. George's, Hanover-square, during 1888, we regret to see, uses the term "mean duration of life" in an incorrect sense. He states that his district had last year "an increased mean duration of life." This statement might only signify generally that, as the death-rate was lower, a higher mean duration of life was thereby indicated. When, however, it is further and precisely stated that "the mean duration of life in Mayfair was 73·60 and in Belgravia 52·89 years," it becomes necessary to inquire what is meant by this use of the term "mean duration of life." It is not difficult to guess that mean duration of life is here used to describe the mean age of the persons dying in these registration sub-districts during last year. Mean duration of life is a term which is recognised by all mathematicians and vital statisticians to signify the mean number of years lived by a population traced by the life-table method from birth to death. There is scarcely a more fatal fallacy in the treatment of mortality statistics than that which deals with the mean age at death in a population, as if it were the true mean duration of life, and bases conclusions thereon as to the longevity and sanitary condition of the population. It ought now scarcely to be necessary to point out that the mean age at death of a population depends more upon its proportional age distribution than upon its health condition. A low mean age at death may only indicate that the mean age of the living population is low; and, on the other hand, a high mean age at death may only indicate that the mean age of the living is abnormally high. But for Dr. Corfield's fallacy, we should have deemed it unnecessary again to urge that the mean age at death is absolutely useless, nay, entirely misleading, as a comparative test of health-condition. The very fact that the birth-rate in Dr. Corfield's district in 1888 was but 18·7 per 1000 (against 30·7 in the whole of London), to which attention is called, is sufficient proof of the abnormal character of the population, and of the small proportion of children it must contain. Can Dr. Corfield, moreover, really believe that the average duration of life in Mayfair is more than twenty years in excess of that in Belgravia? Even if the figures had been called by their right name, as the mean age at death in 1888, no useful purpose could be served by putting them out, as we very much doubt if correct statistics would not show that the mean duration of life is fully as long in Belgravia as in Mayfair. Even in the comparison which is drawn between the so-called "mean duration of life" in the district in 1875 and in 1888, we are doubtful whether the conclusions as to the increased longevity in the district are sound. It is stated that the mean duration of life has increased from 46·67 in 1875 to 58·37 years in 1888. It is quite certain that neither of these figures gives any indication of the true mean duration of life in the district; and unless it had been stated how the deaths in the union workhouses were treated in the calculation for those two years, it would be impossible to judge whether the figures fairly represent even the mean age at death of the population belonging to the district in those two years. St. George's, Hanover-square, has doubtlessly, like the rest of London, been liable to a declining death-rate in recent years, but the decrease of its birth-rate has probably been far greater than in other parts of London, and hence a part of the increased mean age at death cannot be credited to improved sanitary condition. It is scarcely necessary to point out that Dr. Corfield's assertion that the "mean duration of life" in the whole of London has increased from 34·24 in 1878 to 41·77 in 1888 is also invalidated by the faultiness of his method.

THE ITALIAN PREMIER ON STATE MEDICINE.

IN his great speech at Palermo on the 14th instant Signor Crispi gave special prominence to what his administration had effected for the sanitary rehabilitation of Italy. "For four years," he said, "there had weighed on Italians the incubus of an epidemic"—cholera, to wit—"which, besides physical suffering and material loss, had induced a moral disturbance, inevitable, perhaps, in a country where hygienic education was still so primitive and so sporadic. It was a prime necessity, therefore, to proceed at once to the sanitary rehabilitation of the State, and we made provision accordingly. We addressed ourselves first to the minds of men, and we prevailed on them to look the enemy in the face as the principal means of overcoming it. With anxious and systematic care we took the sting from present evils, and then we reconstructed laws to obviate their recurrence. Sanitary provisions should impose on the freedom of the individual no restrictions but such as are required for the safeguard of the lives of others. Personal hygiene is on that account one of those salutary measures which we are entitled to exact." In cognate spirit the municipal services were unified and at the same time reformed throughout the Peninsula; while, continued Signor Crispi, "we modified the constitution of the Sanitary Councils, so as to ensure an earnest and an unremitting surveillance over the public health. We restored to its proper centre—the Home Office—the direction of the seaboard lazarettos, and, by furnishing the chief ports of the kingdom with the means of precaution and defence, we established an outpost system to make head against the importation of disease. By decree and by law of favour (*legge di favore*), we assisted the minor communes in carrying out their sanitary rehabilitation—an opportunity of which already more than three hundred have taken advantage. By a modification and extension of the Bill, enacted for the benefit of Naples, the application of which to themselves was craved by some sixty communes, by considerately evoking and approving plans of house-reconstruction (*piani regolatori*) we have brought to the great cities the blessings of effective resanitation." Nor have more strictly medical reforms been neglected. "We have reconstituted," said Signor Crispi, "the whole vaccination service; we have revised the Pharmacopœia; and on the frontier towns, as a safeguard against epizootic invasion, we have brought up the veterinary stations to military efficiency. We have wrought, in a word, the practical consummation of that sanitary code whose fundamental idea will prove not the least title to the love and veneration long earned from all Italians—whether surviving comrades, or of future generations—by that soldier of science, of fatherland, and of freedom, Agostino Bertani. Thus we may pronounce ourselves as on the true path of that sanitary redemption for which, not less than the political, Italy was yearning—a redemption of equal necessity, and certainly not less of a blessing. An Italy sound in a physical sense will yield us those vigorous arms which will fertilise her the best—those hardy constitutions which as living ramparts will prove her strongest safeguard." The "youngest of the Great Powers" is to be congratulated on the enlightened legislation set

Digitized by Google

forth in these eloquent periods. It will henceforth be her duty to develop, as well as maintain, the sanitary reforms she has effected, and to justify in this respect the position she has earned in the European State-system.

"SOME CONDITIONS OF CHILD-LIFE IN ENGLAND."

AN able (if needless) defence of the Act for the Prevention of Cruelty to Children is contained in a paper just published by Mr. Benjamin Waugh under the above title. The catalogue of cruelties herein briefly summarised is amply sufficient to prove the necessity of such interference between guardian and child as the Act sanctions. We would willingly ignore the existence of the deliberate and pitiless tortures described in these pages did we not know that many such instances of savagery have been only too well authenticated. It is noteworthy that these excesses do not occur with especial freqency where poverty and ignorance might be supposed to have numbed the moral sense of their perpetrators. They appear to be the distinguishing mark of hard and intolerant natures in every rank of life. Anger, the desire for gain, mere brutality, even "fun," have each been assigned a share in their causation, and the process of suffering has gone on, as this paper shows, in the midst of, and untouched by, adjacent religious and other civilising influences, until the arm of the law has intervened on behalf of its helpless victims. The difficulty of obtaining evidence from the occupants of these desecrated homes has now been done away with, and merited conviction has become the more possible. Mr. Waugh is justly forcible in his condemnation of the abuse of infantile insurance, by which "the parent bets a penny a week against the insurer's thirty shillings that his child won't live." He allows too little for ignorance in his condemnation of those who mismanage (often, we admit, wilfully) the feeding of infants, but he will command universal support in his castigation of that purblind charity which grants a passing dole to any idle tramp who bids for sympathy with the misery of some wretched show child. Without prejudice to the reforming power of Christian persuasion, there is need, as he tells us, of the robust and protective righteousness expressed in the Prevention Act.

DRINK MADNESS.

IN the current issue of the *Contemporary Review* a forcible article appears from the pen of Mr. James Runciman, in which he deals with the "ethics of the drink question." Few have had greater opportunities of studying the appalling ravages which drink madness has made in our midst than Mr. Runciman, and still fewer have the power of portraying in all their loathsome hideousness the effects of this foul disease. He denounces as valueless the dry-as-dust statisticians who would by their figures prove either the enormity of the nation's backsliding in respect of drink, or with smug complacency assure us that the revenue returns prove an amelioration of our national sottishness, according as their interests are opposed or in favour of the liquor trade. He is not inclined, after the manner of the temperance rhetorician, to inveigh against the State support of the liquor traffic and hurl invective at the selfishness of distillers and brewers with their *fidus Achates*—the publican. The mild eloquence of the drawing-room zealot who has never tasted alcohol and who preaches to a select audience of total abstainers has no charms for Mr. Runciman. He bids us go forth with him into the dark places of our great city, and see in the brilliant West-end music halls and the drinking hells of Whitechapel the results of drink upon our youth. Nor does the evil begin and end in sapping the growing manhood of our cities. In the homes alike of rich and poor the women have learned the fatal habit of "nipping," and slowly but surely become confirmed dipsomaniacs. It is unhappily too true, as is pointed out in the paper before us, that the vice of drinking, glorified in verse and rendered amusing in prose by our best authors, is sure to form an unholy trinity with betting and unchastity, and as a consequence will sooner or later impair the mental and physical vigour of the individual and impress a taint of which he and his offspring must alike bear the burden. Mr. Runciman does not, however, tell us much in the way of curing the evil; he regards the adult toper as hopelessly incurable, and urges that for the treatment of the young emigration alone offers a hope of reformation. In our daily life we, whether as consultants or general practitioners, perhaps more than any other profession, are brought face to face with the drink question and how to deal with it. The medical man's *rôle* in society is daily growing in the direction of teaching his patients how to avoid disease, and so the great problem of how to grapple with and check the vice of drunkenness must come home to us for solution, and should, we think, occupy a more prominent position in our academics and our thoughts as practitioners than has heretofore been the case.

"ANGLO-AMERICAN VIENNA MEDICAL ASSOCIATION."

A MEETING of British and American physicians was held recently at Vienna to consider the question of establishing an association for the purpose of furnishing all needed information to English-speaking medical men, coming to study in Vienna. A large proportion of those now in the city were present, and it was resolved to start such an association, under the title of the "Anglo-American Vienna Medical Association." A committee of management was appointed, whose chief duty will be to supply information to newcomers on their arrival as to matriculation, medical courses, lodgings, &c., and when necessary, to call meetings of the association. The committee, on the occurrence of vacancies in their number through members leaving Vienna, will fill these up as soon as possible. The office of the Association will be at No. 12, Landesgerichts Strasse. It was agreed that membership should be open to any British or American physician or medical student on payment of an entrance fee of one gulden. The committee expect that towards the end of October the Association will be in working order. Meanwhile letters of inquiry, addressed to the president or secretary, will at once receive attention.

TUBERCULOUS MEAT AT BELFAST.

THE recent memorable inquiry at Glasgow into the necessity for enforcing the destruction of the carcases of beasts subject to tubercular disease, although this may be comparatively limited in extent, has, as we have lately mentioned, excited considerable attention in Sheffield among dealers in meat, and has also within the last two weeks come before the courts at Belfast on more than one occasion. In the first case the destruction of the carcases was ordered. In the second, heard before the magistrates in the Custody Court, on Oct. 11th, the bench refused to give an order for the destruction of the carcases, on the application of the corporation, through Mr. Spiller, who stated that although the flesh was to all appearance good, tuberculosis was found to be present in the lungs and livers of the animals. Mr. Eaton, in delivering the decision of the bench, said that he was not inclined to give such a decision as would have a ruinous effect upon the cattle trade of the country, and would touch both the farmer and the butcher. If tuberculosis were a serious disease like pleuro-pneumonia, the Government should make provision for the compensation of fleshers. This decision was, however, contravened

Digitized by Google

in the third case, which is as follows. At the Belfast Police-court on Saturday, Oct. 19th, an application was made on behalf of the corporation, as the sanitary authority, for an order authorising the destruction of two carcases of beef which had been seized in the public slaughter-house a few days before. Great interest was taken in the case by the butchers, professional men, and by the general public. After a food inspector (who had seized the carcases) and a veterinary surgeon had given evidence, Dr. Burden, Pathologist to the Royal Hospital, proved that on examination he had found both carcases affected with tuberculosis, and that there were bacilli in the liver. Dr. Calwell and Dr. O'Neill also gave evidence that they had discovered tubercular disease in both carcases which they condemned as unfit for food. A veterinary surgeon and a butcher having been called for the defence, the magistrates consulted, and Dr. McGee, who gave their decision, said the Bench looked on this as a very serious matter. The butchers had his sympathy, as they were a respectable body of citizens, and had been brought there without any knowledge of having done injury. They had purchased the animals without the knowledge that they were diseased, and had run the risk of losing the money. However, their interest was a minor consideration to that of the public at large. The magistrates would make an order for the destruction of the carcases. We think the fact that such contrary decisions can be arrived at proves the necessity for an explicit declaration on the subject by the authorities. If it be held that the presence of limited tubercular disease signifies general blood contamination, as may be legitimately inferred from the scientific evidence adduced at Glasgow, that given by the Paris Congress, and in the Departmental Committee, then the practice of condemning the flesh of such animals as unfit for human consumption should be made obligatory, and the country be spared the continuance of a conflict of interests and of magisterial decisions.

AN ERROR IN DISPENSING.

SULPHATE OF ZINC and sulphate of magnesium resemble each other closely, as every beginner in materia medica well knows; but outside the examination room it is not often that they are mistaken. The possibility of error is so fully recognised that they are usually kept far apart and carefully labelled. It is only in student days that laborious efforts are made to distinguish them by the relative moistness, by their adherence to the sides of the bottle, and other minute differences. The taste is characteristic, but this is not generally felt to be a very desirable method of distinction. With insufficient labelling, however, and with unskilled dispensing, mistakes may occur, and such an error recently formed the subject of a serious inquiry by the Birmingham Board of Guardians. Three bedridden old women in the workhouse were one evening taken very ill with vomiting, and it transpired that they had been given some "stock mixture," which should consist of Epsom salts and peppermint. It appeared that this had been compounded, not by the dispenser, but by an old man known as "the bottle washer," who was not a paid officer but a pauper. He had confused two barrels containing respectively Epsom salts and sulphate of zinc and alum, and had made up between three and four gallons of mixture from the latter. It is said that the old women soon recovered and were "really nothing the worse for the mistake." It is very fortunate that the effects of sulphate of zinc are so readily apparent and of such little moment, but the action of the Workhouse Management Committee in suspending the dispenser who deputed the old pauper to compound the mixture is distinctly to be commended for its prudence. These are not the only two drugs which closely resemble each other, and it is quite conceivable that, under like conditions, far more serious mistakes might be made, and with drugs which might be absorbed before the detection of the error.

MEANS OF ISOLATION FOR THE SUBURBS OF LONDON.

WE are glad to find that the Metropolitan Asylums Board have taken a step in the direction of limiting the use of their hospitals to the inhabitants of the metropolis; and that they propose asking for the issue of an order of the Local Government Board to give effect to their wish in this respect. One of the grounds they name is a perfectly right one. It is that if they make arrangements with the authorities of outlying districts for the isolation of infectious diseases from such districts, they are practically aiding the authorities of these districts in making default as to the proper provision for the isolation of the inhabitants in the outskirts of London. That such default has been favoured by the action referred to is well known; a number of sanitary authorities around the metropolis having formerly made some sort of arrangement, both with the Metropolitan Asylums Board and with the London Fever Hospital, to receive their cases; and it has generally been found that the arrangements in question have been largely on paper only, and that they have resulted in the infliction of a distinct wrong on the suburban districts concerned. We believe we are correct in saying that the London Fever Hospital has for some time past refused any longer to entertain such an arrangement; and it will, in the end, be for the public good that the Metropolitan Asylums Board should limit the use of their hospitals in the way that has been provisionally decided on. There is, however, one consideration which might fairly be entertained before the final decision is arrived at. It is well known that the Asylums Board, desiring, amongst other things, to avoid large aggregations of infectious patients in populous metropolitan centres, have not hesitated to go outside the area of their jurisdiction for the erection of some of their hospitals; and it appears to us that where a hospital for Londoners has been put up in an extra-metropolitan sanitary district an arrangement, subject to reasonable restrictions, might fairly be made as to the admission into such hospital of cases from the sanitary district in which the buildings are situated. This is a principle which has, we believe, been admitted in regard to some provincial hospitals; and it is one that deserves consideration in connexion with the step that is now in prospect.

REMARKABLE SUICIDE WITH PRUSSIC ACID.

A CASE of suicide by prussic acid was investigated by Dr. Diplock at Hammersmith last week. The unfortunate woman seems to have been the mistress, or rather one of the mistresses, of Alfred Pollard, chemist, of Glenthorne-road. She came, under the influence of drink and in her nightdress, to his premises at 1 o'clock on Tuesday morning, and found a rival woman there. Whereupon a quarrel ensued. The chemist, according to his statement, seized a weak preparation of prussic acid which he kept for poisoning cats, threatening "to do for himself." He gave the bottle containing this fluid to a boy who had come with the deceased, to hold till he got a measure. Whereupon the deceased got hold of it and drank enough to kill her in forty minutes. The chemist protested that he never meant to poison himself, which is probably true enough. But his whole behaviour in this business was disgraceful. He displayed a self-possessed air and described himself as "partly a doctor" to Dr. Alderson, who was not called till the woman was quite dead. Pollard also, with surprising coolness, in the midst of a situation that would have disturbed most men, countermanded the order to the boy to fetch a

Digitized by Google

policeman. The jury returned a verdict of "Death by misadventure," and properly censured Pollard for putting the poison within her reach, and also for not sending for medical aid after she had taken it. As Dr. Alderson said, if she lived forty minutes, and the poison was as diluted as was represented, there might have been a chance of saving her life with suitable remedies. It calls for the consideration of the Pharmaceutical Society, though we are not sure that they can inflict any adequate punishment on so unworthy an Associate.

SALARIES AND REPORTS OF MEDICAL OFFICERS OF HEALTH.

AN important circular has been issued by the Local Government Board with regard to payments to County Councils out of the Exchequer contribution account, in which attention is drawn, amongst other things, to the effect of Section 24 of the Local Government Act, 1888, on the salaries of medical officers of health who persistently delay issuing their annual reports. That section states that if the Local Government Board certify to the County Council that any medical officer of health, in respect of whose salary a payment would otherwise be due from the County Council, has failed to send in to the Board such annual report and returns as are required of him under the regulations as to his duties, no payment is to be made to the local authority in respect of his salary, but a sum equal to one-half of his salary is to be forfeited to the Crown. The issue of the circular at the present time implies that towards the end of October the time has arrived when those officers who have failed to report on a year which closed nearly ten months ago may properly be dealt with in the way described. But it is to be noticed that the forfeit affects also the sanitary authority, and that County Councils are urged, before making any payments, to inquire as to the receipt of the reports; hence it becomes a question how far medical officers of health whose reports are in arrear will have any claim on their authorities for the moiety of the salary forfeited. It is therefore of the utmost importance that all outstanding reports for 1888 should be sent in forthwith.

GOVERNMENT BY MUNICIPALITIES.

ON Tuesday last the Lord Mayor of the City of London entertained at dinner a number of the mayors and town clerks of the different municipalities and other distinguished guests, including the President of the Local Government Board, the United States Minister, and Dr. Chantemps, the President of the Municipal Council of Paris. Mr. Ritchie's speech will be read with considerable interest by all who have followed the great changes in local government brought about by him. He was able to show that the Local Government Board had aimed not at impeding but at assisting the local governing bodies in their efforts. Speaking of the advantages which had resulted from municipal government, he claimed that municipalities had reduced the death-rate by providing healthy surroundings, a good water-supply, good drainage, and good government in the centres over which they had control, but they had not done all that they might do. He discussed at length the necessity for activity on the part of sanitary authorities in maintaining houses occupied by poor persons in proper habitable condition, and pointed out that where there had been failure the administration, rather than the law, was to blame. At the same time he promised that so long as he was President of the Local Government Board every assistance which could be rendered by the central authority would be given to those upon whom devolved the duty of removing conditions which were prejudicial to the interests of the poor. No one will doubt that Mr. Ritchie intends to adhere to every word he has said, and that so far as in him lies every facility will be given for perfecting the administration which is required for the better government of towns, and especially for improving the circumstances under which poor persons now dwell. There are many engaged in working under the various Acts of Parliament dealing with this subject who see the need for amendments for the purpose of making operative the intentions of the Legislature. Mr. Ritchie's aid will be needed for bringing about the changes which are desirable, and it may be seen from his speech that any well-devised measure will have his support. So far as London is concerned, it is satisfactory to find that the Lord Mayor expressed his preference for a uniform system of government for the whole metropolis; but some doubt will be felt by many whether this could be best obtained, as he believed, by the constitution of a series of boroughs. However this may be, it is probable that the whole subject of metropolitan government will in a few years be brought under consideration, and that a further effort will be made to weld into one the great metropolis. By this time it will be possible to express judgment upon the London County Council, and upon the capacity for administration shown by this body the future of London government must largely depend.

SODA WATER ON DRAUGHT.

A CORRESPONDENT supplies us with some particulars of patents now on view in operation at the Brewers' Exhibition at the Agricultural Hall, which, besides being of great interest, seem likely eventually to be of practical utility to the profession, more especially, perhaps, to the hospitals, where economy is a matter of such importance. "Tubes," as they are now commercially called, which have been so long known to the medical profession for the storage of nitrous oxide gas, are being used for the charging of water, or any fluid such as wine, milk, &c., with carbonic acid gas brought from springs in Germany, where it is given off in a pure and unadulterated state. By simple but very efficient mechanism any filtered water can be made equal to the best waters as sold bottled. Oxygenation, aeration, the charging of waters or wines with carbonic acid gas, can all be done at home at a very small cost, one penny for the charging of the fluid equivalent to one dozen bottles. To hospitals this will be an immense saving. It is virtually soda water on draught. One large place of amusement is said to be about to adopt the process, and will be able to serve effervescing water at almost a nominal cost.

ARTIFICIAL FOOD FOR INFANTS.

DR. ESCHERICH of Munich gave a lecture in the Pædiatric Section of the sixty-second meeting of German naturalists and physicians at Heidelberg, advocating a reform in artificial feeding of infants. He bases his belief in the necessity of such a reform on the errors produced by Biedert's theory, which depends upon the difference between cow's milk and normal human milk. Biedert's view was that all the troubles and diseases occurring in artificially-fed infants were due to the indigestion of the caseine of the cow's milk, causing irritation of the mucous membrane of the bowels. He therefore considered that if the latter were diluted so as to contain 1 per cent. only of caseine, the infant could not possibly take an injurious quantity of this noxious substance. Dr. Escherich considers that this theory and the practice resulting from it have gone far to prevent due care being exercised as to much more important conditions. Such are, according to the lecturer, germs and fermentation in improperly kept cow's milk, the

Digitized by Google

number of meals, and the quantity of food given at a time in proportion to the capacity of the infantile stomach, the total quantity of nutritious matter and its proportion in the food, and finally the injurious effect which the water which has been added to the food has on the digestion and the metamorphosis of nutritious matter. Dr. Escherich holds it above all necessary to return to physiological principles, and so to approximate artificial feeding as much as possible to the mother's milk, as regards the absence of germs and the number and quantities of meals. The lecturer then pointed out that it is easy enough by sterilisation of small quantities of milk according to Soxhlet's plan to comply at least theoretically with all these conditions, and at the same time to limit the quantity of caseine so as to fulfil Biedert's requirements. This method, which Dr. Escherich calls volumetric, as opposed to Biedert's percentage method, is best applied by Soxhlet's apparatus provided with graduated feeding bottles.

THE ISOLATION OF INFECTIOUS DISEASES IN SALFORD.

WE are glad to find that, as the result of the recent emergency which has arisen in Salford by reason of the prevalence of scarlatina and diphtheria, the long-standing difficulty as to the best method in which to provide for the future isolation requirements of the borough has been solved, the Corporation having decided, on the motion of the Mayor, to approve of the purchase of the hospital site in the Eccles New-road, which was made the subject of lengthened inquiry before Commissioners appointed by the Local Government Board, and for the purchase of which a loan was sanctioned by that Board several months ago. This will give the Corporation an area of thirteen acres in a locality which, according to the evidence brought before the Commission, is likely before long to be one where a hospital will be much needed; for not only is it expected that the Manchester Ship Canal, which runs close by, will bring a large number of working men's houses to the locality, but the canal itself will in many respects form part of that which will practically constitute a port sanitary district.

AN ELECTRIC TYPE-WRITER.

WE have been favoured with a view of an instrument invented and improved by Mr. F. Higgins, C.E., for printing news transmitted by electricity on a sheet of paper in column form, in a manner similar to that of the ordinary type-writer. The type is clear and bold, with proper spaces between the words and between the lines, and is altogether a distinct improvement upon the "tape," which the new instrument is intended to supersede in the transmission of news to newspapers, clubs, and hotels by the Exchange Telegraph Company. The chief advantage of the "Electric Type-writer," with its speed of twenty-five words a minute, over the tape, consists, from our point of view, in the increased facility it offers for easy reading.

EAR DISEASE AND NERVOUS DEPRESSION.

IN the early days of railways fashionable physicians harped loud and long on the distressing effects on the nervous system of long-continued vibration. This fertile source of nerve mischief has been lessened very much of late by vast improvements in the machinery, especially in the matter of breaks and springs. But there are still many neuroses arising from incessant and comparatively speaking violent vibration on peripheral nerves. One of these is ear disease in its common kinds. There cannot be the least doubt that Ménière's disease in not the only neurosis which results from aural mischief. To be convinced that low spirits and inertia with absolute disinclination for work are frequently largely to be attributed to auditory derangement is very necessary for successful treatment. Indeed the depression or melancholia may take the form of paroxysms as definite in their way as those of labyrinthine vertigo. Derangements of digestion, of circulation, and of excretion are powerful in helping the ear mischief to produce nervous symptoms. This is a matter deserving of great consideration in undertaking the treatment of cases whose primary and principal cause is in the organs of hearing.

COMPULSORY VACCINATION IN NEW SOUTH WALES.

THERE seems but little question that the principle of compulsory vaccination is extending, and this especially in English-speaking communities. It has been adopted with varying degrees of stringency in portions of the United States, of Australia, and also in Canada, and now we find that the Board of Health of New South Wales are pressing the Legislative Assembly to pass an Act giving effect to the same measure in that colony. The secretary urges on behalf of his board that compulsory vaccination is "the only known method of successfully avoiding the ravages of small-pox;" that the power of quarantining infected persons is insufficient to prevent the spread of the disease when imported; that such compulsion is in force in the whole of the Australasian colonies, except New South Wales; that where it has been in operation its action has been generally satisfactory in the prevention of disease and death, and that "in no instance has the Act been repealed;" and they finally express their hope that, "in view of the extreme gravity and urgency of the danger to which the colony is subjected, a Bill for the establishment of compulsory vaccination will forthwith be introduced."

THE NEW ENTRIES.

SINCE our last issue we have received the following additional returns of fresh entries for the current winter session (1889–90) at various provincial medical schools:—

	Entire Course.	Occasional.	Total.
Bristol Medical School	25	1	26
Cambridge University*	117	—	117
Liverpool, Victoria University†	43	13	56
Manchester, Owens College‡ ...	75	32	107
Sheffield School of Medicine§ ...	13	2	15
Yorkshire College	33	5	38

* The distribution of Cambridge freshmen intending to study medicine is this year more equally apportioned among the several colleges than in previous years.

† The figures last year were 51 and 9 respectively (total 60).

‡ The following is the exact position at this school:—First year's men, 75; occasional students, 32; dental students, 11; students entered for preliminary scientific course, 51; total 169.

§ The total number of students of all classes at this school is 40.

SCHOOL CLOSURE AND MEASLES AT SPALDING.

DR. MORRIS has given notice that he will move the adoption of the Act relating to the notification of infectious diseases in Spalding. A prevalence of measles has given immediate prominence to the subject; and incidentally it is stated in a report of the proceedings of the Improvement Commissioners that the medical officer of health had advised that the Board schools should be closed, but that the school authorities had not complied with his advice. Since needless delay in this matter often arises from failure to proceed in a regular way, it should be remembered that it is only on the order of the sanitary authority that the school authority is required to act; the medical officer of health's duty in the matter being solely to advise the sanitary authority to order the closure.

Digitized by Google

CAMPHO-PHÉNIQUE.

A NEW ANTISEPTIC for use in dental surgery—campho-phénique—is, after an extended trial, warmly spoken of by Dr. Flagg of Philadelphia. It is a germicide, an efficient antiseptic, a non-irritant, a decided local anæsthetic, non-poisonous, insoluble in water or glycerine, does not stain or discolour, and is possessed of an agreeable odour, and not disagreeable taste. When required to be used in a diluted form it is mixed with cosmoline or lanoline. He says it will allay the sensitiveness of dentine, and, when mixed with arsenic as an application for destroying pulps of teeth, renders that operation more constantly painless than any other "nerve paste." Should further experience prove that it has this anæsthetic property, it will be of great value. It is also recommended as a surgical dressing for wounds, burns, sprains, intolerable itchings, &c. Campho-phénique is stated to be a definite chemical compound, having a formula $C_8H_{11}O$.

CAN A GUARDIAN OF THE POOR RECEIVE A FEE FROM THE BOARD OF GUARDIANS?

A QUESTION arising out of a fee paid to a medical man, a member of the board of guardians at Hackney, appears to have occasioned considerable feeling in that assembly of the fathers of the parish. It would seem that Mr. R. Smith, the practitioner in question, had received the usual fee for certifying to the insanity of a woman, who was consequently removed to the workhouse. Thereupon, another member of the board objected that Mr. Smith was disqualified for the exercise of his office of guardian, and the question was submitted to the Local Government Board. This authority decided in favour of Mr. Smith, but the guardian who objected refused to be bound by that decision, and intimated his intention of bringing the matter under the cognisance of the Court of Queen's Bench. Should he carry out his threat, an interesting point will arise for discussion; but we hardly think that the opinion of the Department will be over-ruled. The Poor-law Act of 1842 does no doubt provide that a person receiving any fixed salary or emolument out of the proceeds of the Poor rate shall be incapable of acting as guardian of the poor for the parish by which he is paid. But the whole clause in which this passage occurs is aimed at salaried officers engaged in the administration of the Poor-law, and that would seem to be a very strained interpretation of the word "emolument," which would make it cover the case of an occasional fee paid for an occasional service rendered. Still, the doubt exists, and the question has actually arisen. Should it be now determined by legal process, to which Mr. R. Smith is a party, he will have our sympathy, for the lot is a very hard one of the private individual who is made the subject of an experiment in the construction of an Act of Parliament. But, for all that, it will be both interesting and useful to have the question set at rest.

LONDON SANITATION.

AT the weekly meeting of the London County Council last Tuesday, Mr. John G. Rhodes moved the adoption of the report of the Main Drainage Committee, which recommended that application be made by the Council to Parliament next session for the following powers:—"(1) To provide for periodical inspection of drains under houses by vestries or district boards, and for the execution of such works by them as, upon such inspection or otherwise, may in their judgment seem necessary—a clause to be included requiring that means shall be provided for inspecting and testing house drains; (2) to prevent the construction of basements below the level of sewers, except with the consent of the Council; (3) to prevent buildings being erected in places where there are no sewers, except with the consent of the Council." After a discussion the motion was adopted, with the addition of an amendment referring back to the Main Drainage Committee for further consideration and report a recommendation made by that committee, that no notice should be taken of the alleged subletting of work by the contractor in respect of the carrying out of the contract for the construction of sewage precipitation works at the Crossness pumping station. Captain James next moved the report of the sanitary committee, to the effect that the question of public baths and laundries in all parts of London was not one of the questions that pressed most for central administration, that it might be properly deferred until such time as district councils were created, and that the consideration of the question be deferred. Mr. Phillips moved as an amendment that the Council should apply for Parliamentary powers to increase the number of public baths and laundries. After considerable discussion the amendment was negatived, and the report was adopted.

MYXŒDEMA.

DR. KOSMOVSKI recently brought before the Archangel Medical Society an interesting case of myxœdema where not only all the ordinary physical signs of this affection were present, but also mental disturbance. There was, however, no thickening or enlargement of the upper limbs, and the patellar reflex, instead of being diminished, was increased. The explanation suggested of these departures from the typical form of myxœdema was that whereas most of the cases described and brought before medical societies were of long standing and in an advanced stage, in which condition only these cases have usually stood much chance of being correctly diagnosed, this case had developed under Dr. Kosmovski's observation within the previous few months, and so the later developments had not had time to present themselves.

THE INFECTIOUS DISEASES (NOTIFICATION) ACT, 1889.

THE Cambridge Improvement Commissioners, acting as urban sanitary authority, and the Herne Bay local board have already decided to adopt the provisions of the Infectious Diseases (Notification) Act of this year. Such authorities as follow the lead thus given would do well to remember that, with the increased information they will get as to infectious diseases, it will be necessary to make proper provisions for acting on the knowledge acquired, and that adequate means of isolation and disinfection should be provided for this purpose.

SUFFOLK GENERAL HOSPITAL.

WE are pleased to find indications that the disagreement between a section of the governors of the Suffolk General Hospital and the medical staff is in a fair way to be removed. A numerously attended meeting of the governors was held on the 15th inst., the Marquis of Bristol presiding, to "receive the resignation of the medical officers," when, after a prolonged discussion, the following resolution, moved by the Rev. Harry Jones, was carried by a large majority: "That the resignation of the medical officers be not accepted, on the ground that the proceedings at the meeting on Sept. 17th, which have caused them to tender their resignation, were inconsistent with the unanimous decision of the general board on June 18th." It was also understood that another special meeting should be called to rescind the rule to which the medical officers object. There is thus fair prospect of harmony being restored to the institution. The medical officers, Dr. McNab,

Digitized by Google

Mr. Image, and Mr. Kilner, are to be congratulated on the firmness with which they have resisted the attacks directed against them. It may also be hoped that at the next annual meeting all parties will co-operate to place the institution on the best footing for carrying out the purposes for which it is intended.

THE ROCHFORD ISOLATION HOSPITAL.

A COMMITTEE of the Southend local board have visited and reported on the premises that do duty in the neighbouring Rochford rural district as a hospital for infectious diseases, and the report is strongly condemnatory of everything attaching to the place, including its structure, furniture, and administration. In Dr. Thorne Thorne's official report of 1881 on the Use and Influence of Hospitals for Infectious Diseases, this building was spoken of in terms sufficiently disparaging to have condemned its further use; but if any change has taken place, it seems to have gone from bad to worse. It is to be hoped that some proper and decent provision will be forthwith made for the reception of the infectious sick of this district.

THE SEWERAGE OF MARGATE.

A FURTHER important step has been taken towards dealing with one portion of the scheme of sewerage on which Margate has decided, and which will, it is hoped, by June next secure for that health resort a system by which the whole of its sewage will be carried to the extremity of Foreness Point, and thence discharged into currents that will take it finally away into mid-sea. There was at first some opposition to the scheme which Mr. Baldwin Latham is carrying out, but all are now heartily co-operating with the measures in progress.

NUMBER OF DENTISTS IN GERMANY.

ACCORDING to Dr. Paul Börner's "Reichs-Medicinal Kalender für Deutschland" for the year 1888 there are 16,864 medical men and 514 dentists in practice among a population of 46,840,587 inhabitants in the German Empire, while the number of chemists' shops is 4671, and of hospitals 2737. In face of these figures, it may be truly said that the dental profession is not overcrowded in the Fatherland.

THE GENERAL MEDICAL COUNCIL.

A MEETING of the General Medical Council has been summoned for Tuesday, November 26th, at 2 P.M. The Executive Committee will hold a sitting on the preceding day at 1.30 P.M., in accordance with the standing orders, for the purpose, *inter alia*, of preparing the programme of business for the consideration of the Council.

FOREIGN UNIVERSITY INTELLIGENCE.

Algiers.—M. Planteau of Bordeaux has been appointed to the newly created chair of Pathological Anatomy. M. Treille has been appointed to another newly established professorship—viz., that of Tropical Diseases.

Bahia.—Dr. Nina Rodigues has been appointed Assistant Professor of Clinical Medicine.

Cracow.—Dr. Jos Oettinger, Professor of Historical Medicine, is about to retire. A new surgical clinic has just been opened for the reception of patients.

Genoa.—Dr. Morselle, of Turin, has been appointed Professor of Mental Pathology.

Groningen.—Dr. Koch of Amsterdam has been appointed to the chair of Surgery, in succession to Professor Korteweg.

Königsberg.—The temporary charge of the late Professor Jacobson's Ophthalmological Clinic has been given to Professor Vossius.

Liège.—Dr. Firket has been promoted to the full Professorship of Pathological Anatomy and Bacteriology.

Montpellier.—M. Granel has been appointed to the chair of Botany and Natural History, in succession to the late Professor Martins. M. Imbert has been appointed Professor of Medical Physics, in succession to the late Professor Moitessier.

Würzburg.—Dr. Reichel has qualified as *privat-docent* in Surgery.

DEATHS OF EMINENT FOREIGN MEDICAL AND SCIENTIFIC MEN.

THE deaths of the following eminent foreign medical and scientific men are announced:—M. J. Puls, a well-known Belgian entomologist, a pharmacist by profession.—Dr. Landtsert, formerly Professor of Anatomy in the Medico-Chirurgical Academy in St. Petersburg. After retiring from the chair at the end of twenty-five years' service, he employed himself in teaching anatomy at the Academy of Arts.—Dr. Kozloff, who at one time held a professorship in the University of Kieff, where his duties were to teach Pathological Anatomy, Physiology, Anatomy, and the History of Medicine. From 1871 to 1882 he was Medical Inspector in the Medico-Chirurgical Academy in St. Petersburg. For some thirty years he was editor of the *Voyenno-Meditsinski Zhurnal* (the *Military Medical Journal*).

SMALL-POX is stated to have greatly diminished in Chili, owing to the spread of vaccination. In 1880 there were 7254 deaths from this disease; in 1883, 3188; in 1885, 3138; and in 1888 only 1477. The death-rate, however, taken on the whole, is still high, owing to the want of sanitation among the people.

AT the sitting of the Royal Commission on Vaccination on Wednesday, Dr. F. W. Barry was again (the third day) under examination, and it is probable he will be called at the next meeting.

DR. PETER HORROCKS performed Cæsarean section by Sänger's method on Monday last at Guy's Hospital. Both mother and child are progressing favourably.

A CONGRESS of Russian medical and scientific men will be held in St. Petersburg from Dec. 27th to Jan. 7th. It will be divided into eleven sections.

THE death is announced of Mr. Vincent Richards of Goalundo, so well known for his researches on snake poison.

THE first Congress of Polish surgeons has just been held at Cracow.

WASTE OF FISH AND FISH PRODUCTS.

BY J. LAWRENCE-HAMILTON, M.R.C.S.

No. V.

THE alarming, augmenting, avoidable waste of fish and of products made or derivable from fish refuse, together with the waste of immature and of unsaleable fish is a question of national importance. These combined wasteful methods, sanctioned by chronic conventional custom, are factors which tend to increase the price of fish to the consumer, and are a heavy avoidable loss to the fisher-folks of the United Kingdom. In trawling, often the net is brought up without containing a single saleable fish. Whether the unsaleable fish amounts to 50 or 500 per cent. or even more as compared with the saleable fish is a subject upon which fishermen are proverbially reticent. When they do give information on

Digitized by Google

this point their evidence is so opposite and contradictory that the solution of this topic is not thereby advanced. However, when coasting smacks unavoidably catch nothing better than immature and other unmarketable fish, under a rational economic system, this fish should be used up for *the manufacture of waste products which in the United States of America represent upwards of 14 per cent. of the total value of their fisheries.* Excluding the waste of immature and of unmarketable fish, I estimate that upwards of £2,156,900 a year is wasted in the United Kingdom by omitting to work up the waste products of fish after the American plans.

Owing to pressure and other causes, almost all fish caught in the nets are either dying or dead before they are landed into the smacks. British fishermen frequently throw immature and unsaleable fish and fish refuse into the sea. From time immemorial the Chinese and Japanese have profitably worked up and economised the waste products of fish. The Americans boil fish to extract the oil useless for manure, whilst the bones are made into glue and other commercial products, and the remainder is used as manure. The Americans bone and skin their codfish, and pack it in tins; whilst thus making a higher-priced article, they derive extra profit by working up the skins and bones for by-products.

In the United Kingdom valuable waste products, derivable from fish refuse, are usually ignored in every household. Excellent stock or basis for soups can be made from the heads, bones, skins of fish, and of filleted fish, a familiar economy in China, where even sharks' fins often fetch about thirteen pence a pound. A bread of fish "flour" is popular in some countries. English rays are imported to France for making soup; bone earth from fish refuse for manure; albumen from fish blood. A "meat" extract is made from fish; it has no fishy flavour, and is alleged to be better and cheaper than beef extracts. This fish extract mixed up with pea-food, flavoured with herbs and salt, makes a good food-sausage. Herring meal, mixed with starchy food, affords a cheap and excellent food for cows, without giving any fishy flavour to their milk. In some foreign countries domestic animals and poultry are fattened on fish.

The heads, fins, entrails, blood, &c., yield excellent guano. From the skins and bones of fish a strong adhesive cement can be profitably manufactured. The dried skins of the shark, dog-fish, ray, &c., are useful for polishing wood and ivory, and in Egypt serve for the soles of shoes. These fish skins afford a kind of leather called shagreen. The dried skins of flat fish can be used for gloves, "leather" purses, for fining coffee, as a substitute for isinglass, and for artificial baits. The Chinese use painted and varnished fish skins as ornamental lanterns. In Japan wax is made from the skins and intestines of fish. Eel skins serve for whip thongs, and when dressed and dried make braces. In America, cusk and torsk skins have been patented for shoeleather. Siberian peasants clean, stretch, and dry the skin of the turbot for leather bags and as a substitute for glass window-panes. In some parts of Asia the tanned skin of the salmon yields a prettily marked scale-like leather, and ray skins a good imitation of morocco. Imitation porpoise leather is often made from the skins of the seal, walrus, and white whale. The American white fish yield large good upper leather. Indian-ink is obtained from the sepia fish. The roe of the mullet supplies the *botargo* of Italy, and is an ingredient in Indian curries. Besides the sturgeon, the roes of many other fish furnish caviares.

Especially about the middle of February, the decks of boats where cod-fish are killed are actually milk-white with cod-spawn, which should be used for artificially rearing cod-fish, as in Norway. Russian scientists have been specially successful in rearing fish from the roes of dead male and female fish. Mussels, one of the best baits for sea-fish, have often been destroyed to serve as a cheap manure.

RABIES. — The number of dogs in England officially reported during the week ending Oct. 12th as afflicted with rabies was eight, against a similar number in the preceding week. Of these seven were killed, and one died. The distribution was as follows: Sussex (Eastern Division), two; and Essex, Lancaster, Middlesex, Oxford, Surrey, and York (West Riding) one each. No cases were reported from London proper.

LONDON THIRTY YEARS AGO.

THE report for the year 1888, with which the Metropolitan Board of Works has wound up its career, has been made the occasion of a *résumé*, in which that now defunct institution replies to the comments and criticisms which have accompanied its demise by solemnly placing on record the services which in the course of its history it has rendered to the metropolis. Such a narrative can hardly fail to be interesting in no ordinary measure. It is, for example, strange and curious in a high degree to recall now the anarchic condition of London local government so recently as 1855, when the Metropolitan Board was constituted. In the report just issued the picture is strongly drawn. Contemporary testimony to the frightfully insanitary condition of the River Thames and of the slums is quoted from the pages of THE LANCET, and from evidence given by the late Lord Shaftesbury before a Royal Commission, which considered in 1854 the question of the housing of the poor. The description makes one wonder that such neglect of the most elementary principles of hygiene could ever have occurred in a civilised community. The problem of finding adequate room and wholesome dwelling places for the overwhelming population of the metropolis is formidable, and far enough from solution to-day. What it must have been when the river was nothing but an open sewer, and when we were forced to write, "Wheresoever we go, whatsoever we eat or drink within the circle of London, we find tainted with the Thames," it is far from easy to say or even to imagine.

The Board of Works assign the foremost place among the improvements which it has effected to the great work of sewerage and drainage which it has carried out. It is, no doubt, easy to over-estimate the merit of that work. Putting the picture of 1889 beside the picture of 1855, it is most natural that one should be led to exclaim, "What a vast change!" And vast, indeed, it is. But it does not at all follow from that that the reform is complete or the stage attained final. On the contrary, the work which the Metropolitan Board accomplished ought, in our judgment, to be regarded as a mere beginning. The costly and wasteful process of carrying the refuse of London out to sea and casting it away there is wholly unworthy of the science of the day. The historian of the Board narrates with some details the various attempts which have from time to time been made to convert the sewage of London into manure for agricultural use. It is his lot to record of every one of these attempts in succession that they have resulted in disappointment, and the conclusion if not actually drawn is sufficiently indicated that any such undertaking must of necessity be fruitless. We, however, for our part refuse to accept that inference. In spite of all past failures, arising as they have arisen again and again from unfavourable financial circumstances or other faults of management or design, the broad chemical facts remain that this troublesome waste contains highly valuable ingredients, ingredients of which the soil stands in need, and which have to be supplied from other sources at considerable expense. The problem is how to transport it from the place where it is a nuisance to another place where it is a desideratum, and we wholly decline to draw the inference that this problem is insoluble from the meagre data furnished by the unsuccessful attempts to grapple with it which have been recorded by the Metropolitan Board. It may be that considerable alterations will have to be effected in the drainage system which has been elaborated by the Board; it may be that much of the work which it has done has been done upon mistaken lines; but we confidently hope that it will eventually be found that a well-regulated town, even though swollen to the present proportions of the metropolis, can always find upon agricultural land an outlet for its refuse under an arrangement which, while easing the burden of removal, respects the economy of nature.

In perusing this report, we find ourselves more thoroughly in accord with the writer in his comments upon the work of the board in connexion with the preservation of open spaces, and the protection of infant life. Thirty years ago these were subjects which were but little understood, and even

Digitized by Google

less appreciated. In the interval there has been a great awakening of public interest in these subjects, and a corresponding upgrowth of a sound and just sentiment. This development is faithfully reflected in the present report. It appears that during its career the Metropolitan Board had acquired control over parks, commons, and other open spaces to an aggregate extent of upwards of 2600 acres, and secured their permanent enjoyment by the public against the encroachments of private interest. In the regulation and control of institutions and persons whose business is the custody of children of tender years the record of work done is less satisfactory; but something at least has been accomplished in this direction, and will no doubt afford a starting point for further reform. Upon the whole, this report will doubtless tend to improve the position of the late Board in the eyes of the public, who will the more readily forget the misdeeds which brought about its disestablishment in consideration of the great and undeniable services which it rendered at the time when the local government of London was in the process of making.

THE PARIS UNIVERSAL EXHIBITION.

(FROM OUR SPECIAL CORRESPONDENT.)

The Liberal Arts.—America, Russia, Roumania, Holland, Switzerland, Belgium.

THE time is now rapidly approaching when the great Exhibition must close its doors. For those who have watched its development, its gradual ripening, till it reached the zenith of an unparalleled success, the thought that it will all so soon be over conveys an irresistible sense of melancholy. But a short life well spent often leaves an ineffaceable trace in the world's history, and certainly many years, if not centuries, must roll by before the glories of this Universal Exhibition, held as a pacific celebration of a great historical date, is forgotten. Not only has the whole season been one of unusual material and commercial prosperity, but public health has been marvellously maintained throughout. We have had no epidemics, no exceptional sickness; and this, too, both with regard to the general public and also with respect to the large army of attendants and others who have been present and have worked at the Exhibition. I called at the offices of the British Commissioners, and was there informed that all the English officials and assistants had been remarkably free from illness during their now somewhat lengthy sojourn in Paris. Perhaps the improved methods of drainage, though only applied as yet on a very restricted scale, have contributed to this result. Certain it is that the Exhibition itself has been well drained, in spite of the excessive strain resulting from the extraordinary number of visitors. At the English Commissioners' Office there is an interesting illustration of how a good closet may be constructed in conjunction with the most defective and illogical *tinette filtre* system. It is one of Messrs. Jenning's closets with a *tinette filtre* below. This, however, does not prevent the application of a two-gallon flush. As the solids alone are retained in the *tinette*, it does not matter how much water passes through, and consequently no nuisance has arisen throughout the six months the closet has been in use, for the flush was always sufficient. As I have already explained, the new police regulations authorise the application of this system in the worst-drained parts of Paris, and therefore good results could be obtained everywhere if the population were only intelligent enough to avail itself of the new regulation. Messrs. Jenning, besides draining the offices of the British Commissioners, have a very interesting exhibit of sanitary appliances in the machine gallery. Among other things are closet pans that ensure discharge of the flush from a number of small holes at the back and bottom of the pan, as well as from the rim. This, it appears, the French, who are now making almost every form of closet known in England, cannot imitate. They are not yet perfect enough in this manufacture to make the numerous little holes in the pan. On the inner gallery, immediately above Jenning's show, will be found an old acquaintance with a new name. The Crésyl-Jeyes is a French edition of the familiar Jeyes Disinfectant, which in England has been long known and in very general use. In Germany many scientific researches have been made as to its antiseptic qualities, and there is, I was informed, quite a mountain of German literature on the subject. For the treatment of wounds it is said many German surgeons prefer the Crésyl-Jeyes to corrosive sublimate, iodoform, or carbolic acid. These exhibitors are particularly satisfied with what they term a refined preparation of chaste fluid, and which is known in commerce as the Liquor Antisepticus Jeyes.

Before concluding these notices of the Exhibition I would like to insist on the great good achieved by the Liberal Arts Gallery. This is the western wing of the main building, and here may be seen exhibits appertaining to scientific and artistic progress and study. In this wing there are many galleries, where the various nationalities have their respective sections. The English Section contains the exhibits of many publishers, and among them the large volumes of the *Chemist and Druggist* journal. There is a rich show of photographs and photographic apparatus, and notably J. F. Shew and Co.'s pocket apparatus, which has received the highest award given for this specialty. But there is nothing particularly interesting in the English Liberal Arts Section from a medical point of view. In the Spanish Section, which is our nearest neighbour, there is the cabinet of Dr. Macaya of Barcelona, who exhibits all that can serve to illustrate the prevailing method of vaccination from the calf. This is done on behalf of the Spanish Society for the Promotion of Vaccination. Here also are the exhibits of the Seville Deaf and Dumb School. From the Spanish Section the visitor reaches the French scientific educational exhibits. First among these are the collections from the Collége de France and the Ministry of Public Instruction, including all that is used to instruct students in the natural sciences. By the side of this large subject are the apparatus used in Dr. Brown-Séquard's laboratory. Dr. C. Sappey's anatomical specimens illustrating the lymphatic system in men and animals are beautifully arranged. All that appertains to chemical laboratories will be found in this gallery, as also very elaborate charts, plans, and instruments from the Central Bureau of the French Meteorological Society; these include large meteorological photographs and a daily record of weather forecasts, &c. The chemical scales of Messrs. Collet et Fils, who have obtained the gold medal, are in this section, and there is a collection of most elaborate illustrations, plans, and models of schoolrooms, school buildings &c.; here will be noted the improved French methods of warming and ventilation and the realisation of the principle of a unilateral light. All that appertains to the physical exercise and education of children is here also indicated. M. R. Guimard exhibits ingenious methods of in-door gymnastics which can be applied in any ordinary sitting-room. Weights that can be increased or diminished are raised from the ground by means of a rope that passes over a pulley affixed to a wainscoting, and great facilities are also supplied for in-door trapeze exercise. M. Ernest Lalanne exhibits a wooden horse on which anyone in his own drawing-room can learn how to ride. The horse is life-size. To the bridle and stirrups are carefully affixed weights suspended to pulleys. Other weights, from a framework above, can be made to press upon the chest, back, or thigh of the rider. In this manner are produced artificially all the forces of propulsion which render it difficult for the inexperienced rider to keep his seat. Kicking, rearing, bolting, the various hazards of a ride, can be produced in a moment and at will by this wooden horse, and this in such a manner that to acquire the same experience it would be necessary to ride twenty different living horses. M. Lalanne therefore maintains that the science of riding can be learnt much quicker and more completely on his wooden horse than on real horses. However this may be, the wooden horse certainly supplies an excellent and amusing pretext for in-door exercise.

Proceeding through the Liberal Arts Galleries, the exceptional prominence given at this Exhibition to all that relates to anthropology becomes more and more evident. The Société École et Laboratoire d'Anthropologie, which has very appropriately received the gold medal, has, among other exhibits, a small case of exceptional interest. It contains models of the brains of a number of criminals, and the actual skulls of four most notorious and recent murderers. Three out of the four skulls show a marked protuberance of the under jaw. Marchandon is the best known of these four criminals. In the centre of this wing of the Exhibition there are, on the ground floor,

Digitized by Google

the lay figures that represent the history of Labour in prehistoric ages, while above them, in a gallery, are the more serious exhibits of Mr. Francis Galton and Dr. P. Topinard. Twice a week Dr. Topinard attends to give explanations. There are also all the instruments used for the scientific measuring and comparing of heads, &c. Specimens of criminal heads of different ethnological types abound on all sides. The public look in wonderment at all these things. The desire to learn is evident among the crowd, and it is a pity that there are not some cheap pamphlets available so that the most uninformed of the visitors might obtain some general idea of the object of these exhibits. This remark is all the more natural as the anthropological exhibits are surrounded by the classes devoted to printing and publishing, and then to photography.

On the ground floor of the Liberal Arts Gallery will be found a great variety of exhibits relating to technical education, including plumbing work. The Chambre Syndicale des Couvreurs et Plombiers shows numerous types of syphons, that indicate the progress made in sanitary science in France during the last few years. Here also are exhibits bearing on the ventilation of mines. The whole of the east side of the gallery is taken up with a most elaborate display of statistical charts, dealing with every subject—population, death-rates, marriages, stammering, colour of eyes, payment of taxes, amount of travelling accomplished, of alcohol drunk, &c. Before leaving the liberal arts a small American Section should be mentioned, where a few things of interest may be found. Among these M. C. A. Frees of New York, who has been awarded a silver medal, exhibits artificial limbs; the Pomeroy Truss Co. shows apparatus for dealing with curvature of the spine, and W. Schott's antiseptic pocket surgical case. There are, finally, some photographs, illustrating all the services of the Bellevue Hospital of New York.

Considering that the American Government officially supported the Exhibition, and granted a subvention, there might certainly have been a much better display from that country. The American Section is undoubtedly poor. The main part of the section is situated close to the Liberal Arts Gallery. There are a number of scent fountains, and it would seem as if perfumery was in very high favour in the States; but chemistry is not represented in any marked manner. There are some druggists who exhibit, notably Messrs. William R. Warner and Co., of Philadelphia and New York. Soluble coated pills is their specialty, and they show a formidable array of bottles containing every sort of combination in the form of pills. Neat little books explain all the formulæ, and are very practical in assisting the physician to find at once the drug he needs. Close by is Fairchild's pepsine in scales, which has obtained the silver medal. This New York firm asserts that its pepsine contains but a slight imperceptible trace of acid, and that it is not adulterated with added peptone, egg albumen, or milk, sugar, and starch. This preparation has consequently won a large patronage. The Cheseborough Manufacturing Company exhibit a great assortment of vaseline applied as soap, as lubricating grease, and also for a great variety of medical purposes. These preparations are all well known, their utility acknowledged, and it would have been strange indeed if in the American Section there had been no vaseline. In respect to novelties, I discovered only an ingenious apparatus very useful for preparing tinctures. It is a conical-shaped screw with large grooves, which gradually presses the substance introduced forwards; the groove becoming narrower and narrower, the liquid escapes from the open side of the screw container, and by the time the pressed substance reaches the end of its journey it is reduced to dry pulp. This aparatus is introduced by the Enterprise Manufacturing Company of Philadelphia.

The Russian Section is reached next, and though this is also a poor exhibit, there are nevertheless some points of interest. The diagrammometre, for instance, is a wonderful mechanical contrivance for statistical work and the calculation of averages. Its inventor, Victor Kozlaw, is a Russian engineer; and, to quote the words of Count Miliatine, Professor, and at one time Minister of War, the apparatus is like "a head that thinks and speaks." Unfortunately its complicated mechanism defies all description; still it can be understood that it is possible to impart by delicate machinery a record on a dial that shall correspond to the curves of a statistical chart, and that such machinery, if satisfactorily constructed, may be the means of mechanically ascertaining averages, probabilities, &c. Giving proof also of great ingenuity is the apparatus exhibited by the Russian engineer, M. Nadieine. This is a method of domestic drainage by which the solids and the liquids are separated, the latter mixed with ash or sand and converted into dry manure. Near the end of the soil-pipe there is a syphon. After the syphon, the pipe widens out in a fan-like shape, resembling a bottle funnel turned upside down. The solids, by force of gravitation, fall down the centre of this cone, while the liquids, by capillary attraction, follow the walls of the funnel or cone, and are received in a sort of gutter that goes all round it. When this receptacle is sufficiently full, it tilts up and discharges the liquids, either into a drain-pipe (by which they flow to the sewer), or into a special reservoir. This action, by a system of counter-weights, causes a drum to revolve in a case containing the dust, ash, or earth, and liberates a small supply of ash, which falls and mixes with the solids. This apparatus has been in use for nearly a year at the station of the fire brigade in the district of Petrowski, and is said to have answered its purpose well. It is undoubtedly a great improvement on the cesspool system, and may work with some effect where the volume of water used is not very considerable. In the Prussian Section there are also several exhibits of plants and herbs used in medicine. These, for the most part, come from Poland, and are in M. J. B. Segall's stall. M. Mattheisen of Moscow, among other articles used in pharmacy, shows the splendid cantharides for which Poland is celebrated; and Dr. de Korab his preparations of helenine, which he maintains is a specific antiseptic for the germ of tuberculosis. Then we have specimens of the warm clothing the Russian climate renders indispensable, notably V. T. Dichko and Sons' woollen felt boots, sealskin top boots, &c.; and Daria Lavrovna Kretow shawls and wraps of goatshair. Nor should mention of the very sensitive rotative thermometer, for which M. Leon Rabinovitch has obtained the gold medal, be omitted, nor the new kitchener, the "Destructeur Brûleur," where all the household refuse is consumed, thus obviating the dustbin nuisance.

The small state of Roumania has some exhibits bearing on medicine, notable the Roumanian medical preparations of Kónya Brothers of Jassy. Among these, however, it is easy to recognise many familiar French preparations, notably the Tamar Indien. Dr. Severan's glass operating tables are very neat and seem admirably suited for the maintenance of the utmost cleanliness. In the Portuguese Section, the Pharmacia Franco Filhos has received the gold medal for its *vinho nutritivo de carne*. Apart from this meat preparation, another Portuguese firm of chemists, Messrs. Roberto da Costa and Co. of Lisbon, have a silver medal, and display a great number of mercurial preparations. Amongst the Spanish exhibits there is an array of tonic wines, specimens of mineral waters, and a special oil for veterinary purposes, prepared by Messrs. Garcia, Marin, and Co., of Valencia.

The Dutch Section is very rich in all sorts of plants from the Dutch Indies and Java, while Van Houten's, with a model cocoa plantation, cocoa trees of natural size, and a number of æsthetic Dutch houses and cottages, where cocoa is dispensed to the million, is a remarkable exhibition. In France, where the preference is generally given to chocolate, cocoa is now becoming quite popular. In the Dutch Section the same exhibitor has a pretty little Dutch cottage, furnished almost exclusively with diplomas and prizes received all over the world. At this Exhibition he has of course no medal, being *hors concours*. Here close at hand are to be found the very interesting exhibits of cinchona bark and of all the parasites that injure the plantations of this indispensable anti-febrifuge. The Dutch are also large manufacturers of warm underclothing, and we have notably Jansen & Tilames, who exhibit "normal" hosiery, apparently similar to that recommended by Dr. Jaeger.

Of the smaller countries the two most progressive seem to be Switzerland and Belgium. The appliances shown which are obligatory in elementary schools for the teaching of physical science denote a very advanced condition of general education. As much may be said for the chemistry of the superior schools. At the same time the large amount of school furniture constructed on hygienic principles, and so as to facilitate the growth of the pupils, demonstrates that health questions are not neglected. In the Swiss Section, Dr. Laskowski's method for preserving anatomical specimens while retaining their natural suppleness is interesting. Human limbs are exhibited. The

Digitized by Google

muscular tissues, though somewhat dried and shrunk, are thoroughly preserved and flexible. Finally, the relief plan of the Jungfrau (which has obtained the grand prize) and other plans give a graphic conception of the formation of the Swiss Alps and of the health stations situated in these mountainous regions. The pharmacy of Fréd Golliez, from Morat, exhibits articles from Switzerland, and notably a ferruginous cognac that seems very popular.

In the Belgian Section, the charts, statistics, reports, pamphlets, specimen regulations, &c., all denote a country where sanitary science has made considerable progress. There are notably the charts of the Royal Society of Public Medicine. Among the exhibits it may be noted that Dr. Simon of Brussels has obtained the gold medal for his clinical pneumo-dynamic apparatus. Professor Poupart's method of teaching the practice and theory of amputation, with the assistance of lay figures, is interesting. There are, further, a great variety of antiseptic dressings, lints, &c., shown in this section.

It will be seen, therefore, that though many nations have taken no special trouble to be adequately represented in matters relating to medicine or public health, yet, in each section, something may be found that affords interest, and which in a few cases is thoroughly typical of the country of the exhibitor.

Paris, Oct. 17th.

THE ITALIAN MEDICAL CONGRESS.

THE week just closing has been a memorable one for Italian medicine. Signor Crispi's weighty references to State hygiene, which he put in the forefront of his political programme on Monday, were next day followed up by perhaps the greatest medical congress yet convened in Italy—the "Congresso di Medicina Interna" — which held its annual meeting (the second in the series) in the grand hall of the Sapienza. More than three hundred of the profession, including clinical lecturers, consultants, and working practitioners, representing the several schools throughout the Peninsula, were present, while the general public contributed largely to the audience, which included a considerable number of medical students, for whom the railway companies had liberally modified their fares from either extremity of the kingdom to the capital. Professor Guido Baccelli presided, and was supported on the platform by Professors Murri of Bologna, Rossoni of Rome, Maragliano of Genoa, Rattone of Parma, and Cantani, De Renzi, Federici, and Senise of Naples.

The presidential address was in Baccelli's happiest vein. After the customary words of welcome, he congratulated the meeting on the advance it had made over that of 1888, both as to attendance and programme, and then indicated the progress achieved by medicine within the last hundred years. Morgagni cut the first turf, so to speak, of that mighty highway; but his work, exquisite as an artist in the study of nature, restricted itself to the causes and the localities of disease in the sphere of anatomical research. Now the investigation of the etiology of disease has overpassed the province of pathological anatomy, and to-day "in the living and from the living subject are found inexhaustible themes of study." "But," he continued, "it must be confessed that physiological and pathological chemistry have made no such progress as histology and bacteriological cultures. The discovery of micro-organisms themselves no longer suffices us. Leucomaines and ptomaines open up a field of the greatest novelty and difficulty, imposing on the student a far more absorbing task than that presented by pathogenic micro-germs." Dwelling on the distance that divides medicine from the scientific exactitude possible to chemistry and physics, he deplored the exclusive devotion of the best minds to the lessening of that distance, deflecting their energies from the true ground of their application—the clinical. In proof of this he referred to the competitions for medical chairs in the schools, in which the candidates came accredited with every sort of accessory accomplishment without the qualification which was really the central one—clinical knowledge and skill. "I said once," he continued, "and I say it again, that the clinique is the supreme laboratory of experimental human physiology, that the clinique is the school of living anatomy, and that, as handmaids of the clinique, chemistry, microscopy, mechanics, the calculus develop their resources. A true clinician ought to represent, in the knowledge of man, a synthetic force of the first order. He is like the master of an orchestra or like a commander-in-chief—he must know all, and more than all, that the units know, he must be as the multiple to the solos, as the *ensemble* to the components of the harmony. For while ignoring nothing, a clinician makes the appreciation of details subservient to that of the whole, and thus forms his habits and his mental atmosphere, and determines his swift and complex intellectual processes. It is from this that emerges what the lay mind so often admires—his *coup d'œil*, his unerring intuition. And if you ask yourselves what it is that confers such a power, you could not convey it in words. He is like a poet, like a grammarian, who has ceased to remember the rules of prosody and grammar, yet, in writing prose or verse, commits no blunder." Italian medicine, proceeding from old experience to the new analyses, checking and purifying the former by the latter, will place herself on the Via Sacra of truth. "Of this," said Baccelli, "I have the strongest conviction, because she lights her torch at the vestal flame of experimental research, because, in the words of Bacon, she adds to her intellectual resources not feathers to soar, but lead to sound and weights to balance (*non addere plumas sed plumbum et pondera*)." A fine appeal to the audience as a brotherhood in the cause of suffering humanity, and a glowing tribute to the King as an exemplar to all his subjects of philanthropic devotion, formed the peroration of Dr. Baccelli's brilliant and loudly applauded address.

Business began with the joint report of Professors Rattone and Bozzolo on Nephritis, the former discussing its pathogenesis, the latter its treatment. The opinions of previous observers on the origin of the disease were elaborately reviewed, and Professor Rattone, summing up, maintained the validity of the old classification of nephritides into acute and chronic, and showed, as the result of a long series of experiments in which he checked the findings of his precursors, that these maladies are generated by the passage through the kidneys of infective or irritant substances either formed in the system itself or entering from without in the shape of drugs or infections. Professor Bozzolo first set himself to criticise the treatment advocated chiefly in France, by which bloodletting, sometimes in small, sometimes in greater quantity, is practised in acute nephritis, the theory being that the engorgement of the kidneys augments arterial pressure and adds to the labour of the heart. He contended that an ordinary bloodletting can never affect the blood pressure in acute nephritis, while in chronic cases it impairs the reparative powers. Condemning the theory *à outrance*, he passed to other remedies, and objected strongly to diuretics as serving to feed the phlogosis of the kidneys. Warm baths and milk diet were what he mainly recommended—the former for their excitation of the skin to an increase of function, the latter (1) for its diluting the blood and diminishing the density of the urine, (2) for its acting through its contained salts as a mild diuretic, and for its favouring the expulsion of the phlogogenic agents, and (3) for its being a non-irritant food. Professor Baccelli opened the discussion of this conjoint thesis, and was followed by some ten physicians, including Professors Albertone, Maragliano, Giuffrè, and Semmola. To their criticisms (which cannot even be summarised here, but which will be given at length in the official report which the Italian Congress commendably publishes after its sittings) Professors Rattone and Bozzolo replied; and then, in the afternoon, a variety of papers were read and discussed, some of them of special interest, like that of Dr. Petteruti of Naples, in connexion with which he exhibited the "kinesoscope"—a portable instrument devised by himself to register with minute exactness the movements of the several parts of the thorax.

Next day's sitting was in some respects the most important on the programme. Professor Cantani took the chair, from which Professor Baccelli had temporarily retired, to read his elaborate and long-expected memoir on Malaria. Describing its pathogenesis as based on two principal "fulcra"—to wit, the hæmodyscrasia which is manifested in the red globules, and the neuro-paralysis which is revealed in the ganglionic section, he proceeded to show that the palustral infection is a pyrogenic (fever producing) process, but not phlogogenic (inflammation

Digitized by Google

producing). Then he illustrated the double nature of "perniciosa," as determined by individual diathesis and by the nature of the infection; and from this he went on to describe the complications of the fever, its relapsing and its masked forms. Having concluded the nosological part of his paper, Professor Cantani proceeded to review the microscopic researches made in the Roman clinique on more than three hundred malaria patients in the successive seasons of the year, and showed that in grave cases the physician must not rely on merely negative findings in the blood; while the appearance in it of the endo-globular malaric forms demonstrates indubitably the presence of the infection. Passing to the third part of his memoir, the therapeutic, Professor Cantani, in view of the pathogenesis he had established, proposed the direct introduction of the quinine salts into the blood, injecting them, with the usual antiseptic precautions, into the veins. Nothnagel, he said, had *a priori* declared that the intravenous injection of quinine had the same therapeutic value as the hypodermic; but till the present hour Professor Cantani maintained such injections have never been practised with a curative object; only physiologists, in toxicological research, had injected acid solutions, which in animals, as in the human patient, had had highly detrimental results. The form in which he injected the drug was that of a neutral solution of chlorhydrate of quinine in distilled water, with the addition of chloride of iodine in a physiological dose. He then described the phenomena observed after the injection of at first from 0·15 to 0·30, then from 0·30 to 0·60, and finally of the full gramme. With gramme doses he had the best results; all the accessions were cut short without relapse, and this in five cases of very grave "perniciosa." In those cases which resisted repeated hypodermic injections, the intravenous injection never failed once. The elimination of the drug begins after six hours, the morphological alterations of the blood are modified in number and form, and after twenty-four hours the whole have disappeared. Finally, Professor Cantani laid down certain precepts as to the opportune hours for the administration of the quinine; and while disclaiming all intention of formulating general rules for every case of the palustral infection, he said that in all cases of true "perniciosa," when the physician can, without technical inconvenience, employ the intravenous injection, he should practise it not at the beginning of the accession, nor at its height, but at the end of it—that is, at the decline of the temperature, in which case he may be sure that no other accession will recur. This addition to our therapeutic armoury in cases of "perniciosa" has the two precious merits of economising time, and of its being certain that the remedial agent is carried with the torrent of the circulation.

Such is a brief summary of a memoir which Professor Cantani will shortly publish in its authentic form in the proceedings of the Congress. He was followed by his colleague Professor Marchiafava, who went minutely into the pathogenesis and histology of malaria. He examined at length the morphological alterations of the blood, of the red globules, and of the hæmoglobin, and combated the views of Klebs and Tommasi-Crudeli, of Laveran and Golgi, and gave an elaborate description, biologically and morphologically, of the *plasmodium malariæ* in the various forms which he, working conjointly with Professor Celli, had recognised as pertaining to the endo-globular parasite peculiar to the malarial infection. Into this demonstration, given, it must be stated, in so low a voice that he was heard with difficulty, we need not accompany Professor Marchiafava farther than to say that his matter was most interesting, and struck out suggestions which cannot fail to have practical weight in therapeutics. For instance, he made it clear that the organs attacked in malarial fever are: first the brain, then the lungs, then the spleen, then the liver, and finally the intestinal canal. He also showed that the parasitic form encountered in tertian remittents presents different characters from those in other varieties of the fever, and he finally put it beyond doubt that the malarial infection is non-contagious.

In the animated discussion that ensued the chief part was taken by Professor Senise of Naples, who, looking to the origin of the disease, said its proper name should be not "mal'aria" but "mal'aqua," and by Professor Mosso of Turin, who maintained that the blood "is a tissue of our body capable of so many modifications, none of which are properly known, that Professor Marchiafava may easily have been led into fallacy." His criticism, adverse and favourable by turns, evoked an explanatory response from Professor Marchiafava, who also took occasion to rebut the objections of Professor Maragliano. This closed the second day's sitting—the most brilliant of the Congress.

(To be concluded.)

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN twenty-eight of the largest English towns 5709 births and 3433 deaths were registered during the week ending Oct. 19th. The annual rate of mortality in these towns, which had been 17·9, 17·6, and 17·5 per 1000 in the preceding three weeks, rose last week to 18·7. During the first three weeks of the current quarter the death-rate in these towns averaged 17·9 per 1000, and was 1·9 below the mean rate in the corresponding periods of the ten years 1879-88. The lowest rates in these towns last week were 13·2 in Derby, 13·5 in Leicester, 14·5 in Nottingham, and 14·6 in Brighton. The rates in the other towns ranged upwards to 25·1 in Hull, 26·3 in Newcastle-upon-Tyne, 31·4 in Plymouth, and 34·1 in Preston. The deaths referred to the principal zymotic diseases, which had been 529, 403, and 352 in the preceding three weeks, rose again last week to 414; they included 98 from scarlet fever, 83 from diarrhœa, 64 from measles, 59 from whooping-cough, 57 from diphtheria, 53 from "fever" (principally enteric), and not one from small-pox. These zymotic diseases caused the lowest death-rates last week in Leicester and Birkenhead, and the highest rates in Preston, Sunderland, and Plymouth. The greatest mortality from scarlet fever occurred in Sheffield, Brighton, Bolton, Blackburn, and Plymouth; diarrhœa in Leeds and Preston; measles in Halifax, Preston, and Sunderland; whooping-cough in Oldham, Portsmouth, and Wolverhampton; and "fever" in Leeds, Birkenhead, Bradford, and Portsmouth. The deaths from diphtheria included 41 in London, 3 in Salford, 3 in Sheffield, and 2 in Derby. Small-pox caused no death in any of the twenty-eight great towns; and no small-pox patient was under treatment at the end of the week either in the Metropolitan Asylum Hospitals or in the Highgate Small-pox Hospital. The number of scarlet-fever patients in the Metropolitan Asylum and the London Fever Hospitals at the end of the week was 1394, against numbers increasing in the preceding sixteen weeks from 559 to 1343; 188 cases were admitted to these hospitals during the week, against 148 and 177 in the previous two weeks. The deaths referred to diseases of the respiratory organs in London, which had increased in the preceding four weeks from 142 to 264, further rose last week to 300, but were 50 below the corrected average. The causes of 62, or 1·8 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Bradford, Portsmouth, Bolton, and in five other smaller towns; the largest proportions of uncertified deaths were registered in Huddersfield, Sheffield, and Liverpool.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 18·8, 18·6, and 18·3 per 1000 in the preceding three weeks, rose to 20·5 in the week ending Oct. 19th; this rate exceeded by 1·8 the rate that prevailed during the same week in the twenty-eight large English towns. The rates in the Scotch towns ranged from 14·9 and 15·3 in Paisley and Greenock to 20·5 in Aberdeen and 23·1 in Glasgow. The 524 deaths in the eight towns showed an increase of 55 upon the number in the previous week, and included 15 which were referred to diarrhœa, 11 to "fever" (typhus, enteric, or ill-defined), 11 to whooping-cough, 9 to measles, 9 to scarlet fever, 6 to diphtheria, and not one to small-pox; in all, 61 deaths resulted from these principal zymotic diseases, against 74, 69, and 64 in the preceding three weeks. These 61 deaths were equal to an annual rate of 2·4 per 1000, which exceeded by 0·1 the mean rate last week from the same diseases in the twenty-eight English towns. The fatal cases of diarrhœa, which had been 16 and 19 in the preceding two weeks, declined again last week to 15, and were 12 below the number in the corresponding week of last year. The 11 deaths referred

Digitized by Google

to "fever" showed an increase of 6 upon the number in the previous week, and included 4 in Glasgow, 2 in Aberdeen, and 2 in Greenock. The fatal cases of whooping-cough, which had been 15 and 14 in the two previous weeks, further declined last week to 11, of which 7 occurred in Glasgow, 2 in Edinburgh, and 2 in Dundee. The 9 deaths from measles slightly exceeded the number in any recent week, and included 5 in Aberdeen and 4 in Glasgow. The 9 fatal cases of scarlet fever also exceeded recent weekly numbers; 3 occurred in Perth, 2 in Glasgow, and 2 in Leith. Of the 6 deaths from diphtheria, fewer by 7 than the number in each of the two previous weeks, 4 were returned in Glasgow and 2 in Edinburgh. The deaths referred to acute diseases of the respiratory organs in the eight towns, which had been 99 and 87 in the preceding two weeks, rose last week to 118, and were 3 above the number in the corresponding week of last year. The causes of 54, or more than 10 per cent., of the deaths registered in the eight towns were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 31·5, 26 2, and 23·2 per 1000 in the preceding three weeks, rose again to 26·5 in the week ending Oct. 19th. During the first three weeks of the current quarter the death-rate in the city averaged 25·3 per 1000, the mean rate during the same period being 16·4 in London and 17·7 in Edinburgh. The 179 deaths in Dublin showed an increase of 22 upon the number in the previous week; they included 10 which were referred to "fever," 6 to diarrhœa, 2 to measles, 1 to scarlet fever, and not one either to small-pox, diphtheria, or whooping-cough. Thus the deaths from these principal zymotic diseases, which had been 23 in each of the two previous weeks, declined last week to 19; they were equal to an annual rate of 2·8 per 1000, the rate from the same diseases being 1·8 in London and in Edinburgh. The 10 deaths referred to "fever" exceeded the number in any week since March last; while the fatal cases of diarrhœa showed a further decline from recent weekly numbers. The deaths of infants showed a further considerable decline from recent weekly numbers, while those of elderly persons showed a marked increase. Six inquest cases and 5 deaths from violence were registered; and 70, or considerably more than a third, of the deaths occurred in public institutions. The causes of 15, or more than 8 per cent., of the deaths in the city were not certified.

HEALTH OF RANGOON IN 1888.

A copy of Dr. T. F. Pedley's report on the health of the municipality of Rangoon in 1888 has reached our hands. This report throws much useful light upon the unsatisfactory health condition of this urban community, and deserves the serious consideration of the Municipal Commissioners as the sanitary authority of the city. Rangoon, at the time of the last census in 1881, had a population of 134,176 persons, of whom 91,504 were males and 42,672 females; there were therefore only 47 females to each 100 males. Dr. Pedley has apparently assumed that the population of the city has remained stationary since 1881; but, in the face of a table in his report showing an excess of more than 100,000 of immigrants over emigrants at the port of Rangoon during the five years 1884–88, it seems reasonable to think that the population of the city in 1888 was considerably larger than at the time of the last census in 1881. We hope, therefore, that Dr. Pedley's calculated death-rate for 1888 is overstated by an under-statement of the population; but, after making due allowance for this probable over-statement of the death-rate, the report contains conclusive evidence of excessive mortality. It is especially noteworthy that while the death-rate of Christians in 1888 appears to have been but 12·6 per 1000, the rate was 28·4 among Mahomedans, 30·9 among Buddhists, and 48·2 among Hindoos. With regard to the mortality from zymotic diseases, it may be pointed out that the 4574 deaths included 2097 from "fevers," 567 from "bowel complaints," 120 from cholera, and 7 from small-pox. Thus more than half the deaths from all causes were classed under these four headings. The cholera deaths exceeded the number in any recent year, and for the most part are said to have occurred in those localities "where the insanitary conditions are most favourable to its existence." The deaths from other diarrhœal diseases also showed a considerable increase. Small-pox caused in Rangoon 152 deaths in 1883 and 884 in 1884, and the comparative immunity from the disease enjoyed in 1886, 1887, and 1888 is attributed to the successful work of the Vaccination Department. The 2097 deaths from "fevers" showed a marked excess, and were 598 above the average. The greatest mortality from this cause occurred in June and July. A table of the sex and ages at death in 1888 shows the remarkably abnormal age and sex constitution of the population. Under the age of one year, when the numbers living of each sex should not widely differ, the 602 deaths included 352 of males and only 250 of females. The most striking disparity occurs, however, between the ages of twenty and sixty years, in which age-period of the 2740 deaths no fewer than 2225 were of males and only 515 of females. This disparity probably arises from the high death-rate among the coolies, principally from Madras, who are only temporarily resident in Rangoon. Dr. Pedley points out that the city of Rangoon is built upon a partially reclaimed swamp, and that without reclamation and drainage no great improvement of its present unhealthy condition can be effected, as the great majority of the people are living on a soil impregnated with foul organic matter and saturated with moisture. Rain water and fetid sludge are said to form a pool beneath the floors of thousands of otherwise fairly constructed dwellings. A new sewerage scheme is in progress, but Dr. Pedley says, "unless the reclamation of low-lying parts of the town is rigorously undertaken, the new sewerage scheme will lose half its effect." It appears to be difficult to obtain dry wholesome land for building sites, hence land utterly unfit for dwellings is rapidly being built over. These, with the difficulties arising from the large immigration of coolies, who deny themselves proper food and lodging in their effort to save money to return home, are among the causes to which Dr. Pedley attributes the insanitary condition of Rangoon, which is so strikingly reflected in its high rate of mortality. It is satisfactory to note from the local press that the unhealthy condition of the city is now attracting more public attention, and it may be hoped that Dr. Pedley's report will stimulate local public opinion in this important matter.

THE SERVICES.

HORSE AND EQUIPMENT ALLOWANCES.—In the Army Circular of Oct. 1st, a modification is promulgated of the Regulations of 1887, regarding the allowance for horse and equipment, which is applicable to surgeons serving with an army in the field. By the regulation as it stood a surgeon "while serving with an army in the field and necessarily performing mounted duty" was granted £50 to provide himself with a riding horse and horse equipment. In future he may under such circumstances either receive that allowance or be provided with a riding horse from a remount depôt, and horse equipment from public store, or a riding horse from a remount depôt and £10 to provide equipment. "The selection of the kind of issue will be at the discretion of the general officer commanding (or of the adjutant-general of the army if the officer be ordered to provide a horse before embarkation for service). The receipt of temporary duty pay will not disqualify the officer for the receipt of the allowance unless he be acting for an officer who has left his horse available for the duty."

MILITIA MEDICAL STAFF DEPARTMENT.—Surgeon-Major R. H. Rogers, the Waterford Artillery, Southern Division, Royal Artillery, retires under the provisions of paragraph 92, Militia Regulations, 1889, with permission to retain his rank, and to wear the prescribed uniform on his retirement (dated Oct. 19th, 1889).

ADMIRALTY.—The following appointments have been made:—Surgeon Hubert Holyoake to the *Anson* (dated Nov. 1st, 1889); Fleet Surgeon William B. Fletcher to the *Collingwood* (dated Nov. 7th, 1889); Staff Surgeon James W. H. Hawton to the *Victor Emanuel* and Staff Surgeon H. A. W. Richardson to the *Valorous* (both dated Oct. 19th, 1889); Surgeon William Tait to Bermuda Hospital (dated Oct. 19th, 1889); and Surgeon John Hunter to the *Excellent* (dated Nov. 7th, 1889).

VOLUNTEER CORPS.—*Artillery:* 1st London (City of London): Surgeon-Major F. G. Bennett resigns his commission (dated Oct. 19th, 1889).—*Rifle:* 5th (the Hay Tor) Volunteer Battalion, the Devonshire Regiment: Acting Surgeon C. H. Wade resigns his appointment (dated Oct. 19th,

Digitized by Google

1889).—1st Herefordshire: William Broome Giles, Gent., to be Acting Surgeon (dated Oct. 19th, 1889).—2nd (South) Middlesex: Surgeon T. Trent to be Surgeon-Major, ranking as Major (dated Oct. 19th, 1889).—1st Volunteer Battalion, the Highland Light Infantry: Surgeon-Major, ranking as Major, T. Johnston resigns his commission; also is permitted to retain his rank, and to continue to wear the uniform of the Battalion on his retirement (dated Oct. 19th, 1889).

"Audi alteram partem."

THE PRESYSTOLIC MURMUR.

To the Editors of THE LANCET.

SIRS,—In your issue of Oct. 19th Dr. Dickinson has restated the grounds on which he believes that the murmur characteristic of mitral stenosis is due to regurgitation, and therefore occurs during ventricular systole; but he has not attempted to answer the main objections which have been brought against this view, and has made admissions which much weaken the strength of his position. I have so recently stated at length some of the grounds which seem to me sufficient for rejecting Dr. Dickinson's view that I will not repeat them here. I would, however, venture to suggest one or two points in which, as it appears to me, Dr. Dickinson's arguments are inconclusive, or at variance with facts well known and accepted by physiologists and those skilled in experimental research.

Dr. Dickinson states that the "knock" or snap heard at the end of the murmur of mitral stenosis is *at the end* of systole. (The italics are Dr. Dickinson's.) In his former paper[1] he says the "valve allows of regurgitation during the first part of systole, while it is able to close as the systole proceeds, so as to stop regurgitation towards the end of that movement." It is not easy to understand the various periods of the heart's cycle even if, as here stated, the snap comes *during* systole; but if it occurs at the end of systole, it becomes wholly incomprehensible.

a. In this case it would follow that any murmur subsequent to the snap must occur after the end of systole. In mitral stenosis a soft blowing murmur is often heard following the snap, which is generally admitted to be a systolic or regurgitant following a presystolic or direct murmur. But if, as Dr. Dickinson says, the snap is the *end of systole*, this soft murmur cannot be systolic, and there must be some other interpretation of it than that which is usually given. There is, however, no reason to suppose and no evidence adduced by him to show that this is other than, as generally accepted, a mitral regurgitant murmur heard after the *commencement* and not at the *end* of systole. If the first part of the murmur preceding the snap be really regurgitant, and the second soft blowing murmur which follows it be also regurgitant, then there are two murmurs generated by a flow of blood in the same direction and at the same orifice, differing entirely in character and often separated by an interval, a possibility which cannot be entertained. It is to be regretted, for the sake of clearness, that Dr. Dickinson does not quote passages in support of his statement of the views of his opponents, but only says that "those who believe in the presystolic or direct murmur believe that the blood may change its direction at a valve, stop, and go back, and the murmur not lose its continuity or change its tone." The only passage I can find in which any such statement is made is by Dr. T. C. Turner, who writes, *not* in support of the presystolic murmur, but in support of Dr. Barclay's—i.e., of Dr. Dickinson's—views; it is as follows: "If it were true that continuity of the cardiac murmur is inconsistent with a reverse of the direction of the blood stream producing it, this would be fatal to Dr. Barclay's view, which implies a reversal of the blood passing through the mitral orifice between the diastolic part and short 'presystolic' termination of the prolonged bruit, often occupying the whole interval between the second sound and first sound of the heart."[2]

b. Further, it would follow, if the snap occurs at the end of systole, that the carotid impulse which most observers admit follows the snap would not be felt until systole is completed; but experimental physiology has demonstrated that the carotid impulse occurs about one-tenth of a second after the commencement of systole, and immediately after the commencement of the expulsion of the blood from the ventricle.

c. It would also follow that although during the ventricular systole blood has been passing backwards through the mitral orifice into the pulmonary circulation, where the tension is admittedly high, it has not during the same period been forced into the systemic circulation, in which the tension is admittedly low. This is quite contrary to what occurs in ordinary cases of mitral regurgitation, in which the carotid pulse follows the first sound immediately, and is felt not *after* the murmur is over, but *during its continuance*. There is no adequate reason given why in cases where there is regurgitation through a narrowed mitral orifice the carotid pulse should be delayed until after the snap, if, as Dr. Dickinson states, the snap be the end of systole. Again, supposing it to be true that the "knock" occurs at the end of systole, the sound due to closure of the tricuspid valves should precede the "knock" by the whole length of systole, for the tricuspid valves, owing to the increased pressure in the pulmonary vessels, close sharply at the *commencement* of systole. Here also there is no evidence brought forward that such is the case; and it does not seem that any constant want of synchronism between the first sound of the right and left sides of the heart has been noted in mitral stenosis. Again, in cases where there is regurgitation through the tricuspid orifice the murmur is admitted to be systolic in rhythm. If it be so, it should, supposing Dr. Dickinson's hypothesis to be correct, occur at the same time as the presystolic murmur. This, as far as I am aware, is not supported by any recorded case. On the contrary, the tricuspid systolic murmur distinctly comes *after* the snap which terminates the presystolic murmur. And again, if the murmur which Dr. Dickinson calls diastolic is really the direct murmur, and if, as he maintains, the first sound of the heart is only valvular, the sharp closure of the tricuspid valves ought to be heard immediately following it, since he maintains that between it and the subsequent rough rumbling murmur is the commencement of systole. This is not borne out by clinical observation.

In order to account for the sharpness of the sound which ends the murmur under discussion, Dr. Dickinson, without giving any grounds for so doing, discards the explanation of the first sound of the heart which is generally accepted. He assumes that it is due only to the closure of valves, and that muscular contraction has nothing to do with it. If this be so, he should explain why it is that the sound of a hypertrophied heart, in which the cardiographic tracing shows the contraction to be long and sustained, is long and booming; and, on the contrary, why in mitral stenosis, where the sound is short and sharp, the cardiograph shows the contraction to have been more rapid and less sustained; and further, he will have to explain why, when the ventricle has a diminished volume of blood to propel, its systole, contrary to all that can be shown by the cardiograph, is prolonged by the whole length of the presystolic murmur.

Dr. Dickinson is evidently not prepared to accept the view I have lately put forward, and, as I hope, not without adequate reason, that the whole character of the presystolic murmur depends on the flow of blood under high tension through a narrowed orifice into a cavity in which the tension is abnormally low, by which means waves of large amplitude are generated and a thrill produced. He, however, not only gives no alternative, but declines to face the problem, saying, "if the thrill accords, as according to my observation it does, with the heaving of the apex, it is systolic and not made as suggested. How it is made I have not to declare. The circumstances of blood thrills may be various." I can hardly think that such an uncertain statement is calculated, as Dr. Dickinson predicts, to relegate the presystolic murmur to a place "among the errors of the past," and to the rising generation to whom he appeals it may safely be left to judge which view is the more in accordance with facts. I am, Sirs, yours faithfully,

Brook-street, Oct. 22nd, 1889. THEODORE DYKE ACLAND.

[1] THE LANCET, vol. ii., 1887. [2] Ibid., Aug. 18th, 1889, p. 317.

THE VALUE OF HYOSCINE AS A SEDATIVE.

To the Editors of THE LANCET.

SIRS,—I note with pleasure an article which appears in the issue of THE LANCET of the 12th inst., on the value of hyoscine as a sedative, and hasten to add my testimony in favour of a drug which I fear is as yet not fully appreciated.

Digitized by Google

In 1887 and 1888, when in residence at the Leeds Infirmary, I frequently gave it under the direction of the physicians and surgeons, and its administration became quite the routine practice in almost all cases of mental derangement. I have also given it many times since. The solution generally used has been one of the hydrobromate, one grain to 200 minims, or of the hydriodide. These were found to be more convenient than the weaker solutions which were tried at first. The usual dose to begin with was $\frac{1}{150}$ of a grain, but this was generally largely increased. I have given as much as $\frac{1}{30}$. Most of the cases that I have seen have been such as occur in the ordinary run of hospital in-patients—notably, delirium tremens, acute mania following operation, and delirium caused by heart disease. In all of these its success has been most marked. The effect of the drug shows itself in from one to five minutes. The patient becomes less noisy, and his articulation indistinct, drowsiness then comes on, and, although in many cases the man seems to fight against the drug, he soon becomes quiet and lies quite still, often with his eyes partly closed. In about half the cases this state gives place to sleep. This is generally accompanied by stertorous breathing and by a peculiar twitching of all the voluntary muscles; the patient can with great difficulty be roused, and his pupils are dilated and do not react to light. Besides the cases mentioned above, I have given it to a man with intense neuralgia of the supra- and infra-orbital nerves. He was a confirmed opium taker, and morphia had little effect on him. Hyoscine frequently gained him some hours' sleep when morphia and chloral had failed. In yet another case, one of very severe chorea, it sent the patient to sleep after many drugs had been tried in vain. As regards unpleasant after effects, I may say that they are not so common as after morphia, though there is often some dryness of the throat and weariness. I have never seen any alarming symptoms caused by hyoscine, and believe that with ordinary caution it is a safe and very valuable remedy.

I remain, Sirs, faithfully yours,

A. S. BARLING,
House Surgeon, North staffordshire Infirmary,
Oct. 13th, 1889. Stoke-on-Trent.

ST. MUNGO'S COLLEGE, GLASGOW.

To the Editors of THE LANCET.

SIRS,—My attention has been drawn to a letter in THE LANCET of the 19th inst., signed by Dr. J. Wallace Anderson. Dr. Anderson, before writing to you, has neglected to ascertain his facts. His statements regarding the action of the Academic Committee and the governors of St. Mungo's College are wholly incorrect. The committee reported to a meeting of the governors held on Aug. 6th, to which all governors were summoned by circular in the usual way, and the appointments were then made. The list was not published till August 20th. But his statement is quite as accurate as many others that have been publicly made by the opponents of St. Mungo's College. Dr. Anderson could easily have obtained accurate information had he desired, for he is well acquainted both with the secretary of the College and with,

Yours respectfully,
Glasgow, Oct. 19th, 1889. W. G. BLACKIE, Principal.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

The Hospital for Women.

THERE has been lately an interesting case of ileo-colotomy at the Hospital for Women under the care of Mr. Burton. The patient, a single woman, was admitted into the hospital on June 6th last suffering from the passage of all her fæces through the vagina. She stated that she had been confined seven weeks before admission; the labour was difficult, necessitating the performance of craniotomy. Two days afterwards fæces began to pass per vaginam, and continued to do so, nothing passing by the rectum except on one occasion. The fistulous opening was high up in the vagina, and involved the lower posterior portion of the cervix uteri and the adjacent part of the vaginal roof. It was further ascertained that the portion of bowel implicated was not rectum but small intestine. As it was considered impossible to repair from below, and as the patient was emaciating rapidly from inanition, it was determined to attempt treatment by abdominal section; and as so much of the circumference of the bowel was lost, it was decided to perform resection of it and leave the piece attached with vagina and uterus undisturbed. As Mr. F. B. Jessett had had considerable experience in the use of Senn's bone plates, he was communicated with, and made valuable suggestions. The operation was performed on the 22nd of August. To add to the interest as well as to the difficulties of the case the patient had been taken suddenly ill with abdominal trouble three weeks before, and a hæmatocele was diagnosed. In consequence of this the intestines were matted together and adherent to adjacent parts of the uterus and the pelvic wall. The portion of intestine implicated was found to be the lower end of the ileum, about four inches from the cæcum. The intestine was first cut across about four inches above the adherent part, the ends were then invaginated, and the serous surfaces united together by continuous suture; the lower end was then dropped. A longitudinal incision was next made on the convex surface of the upper part, about two inches from the end, and one of Senn's decalcified bone plates placed in position. As there was not room to deal similarly with the short piece between the adhesion and the cæcum, it was determined to make the second opening in the colon itself, and in the same way as the one just made in the ileum. This was done, and the bone plates, one in the ileum and the other in the colon, were brought together and tightly tied with very fine silk. The abdomen was then closed in the usual way. There is little further to record. The patient was kept on starvation diet, nothing but strained beef-tea and water being allowed for four or five days. Flatus passed freely from the third day, the bowels were properly opened on the fourteenth day, and no fæcal matter came per vaginam from the time of the operation. The case shows the great ease with which intestinal resection can be performed by means of Senn's decalcified bone plates, in contrast with the tediousness and danger of the best method of suture heretofore in use. Mr. Burton will probably publish a more detailed account of the case later on. Meanwhile it may be stated that at a very recent date the patient, who is under careful medical observation, was reported to be doing extremely well.

Indecent Advertisements.

The Act which will come into force on Jan. 1st next will be of great benefit to this city and neighbourhood, which has too long been disgraced by the display on walls and hoardings of quack advertisements of a most indecent character, with an effrontery almost incredible. In spite of many prosecutions and fines the nuisance continued, and could only have been suppressed by an Act as stringent as that which has been passed, and which will shortly come into force.

The Education of the Deaf and Dumb.

At the next meeting of the Liverpool Medical Institution the attention of the members will be drawn to the recently published recommendations of the Royal Commission on the Deaf and Dumb, and the following resolution will be moved: "That in the opinion of this meeting the combined method of education is to be preferred to the pure oral system for the masses of the deaf."

Liverpool, Oct. 23rd.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

Queen's College.

THE annual meeting of the governors of Queen's College was held on the 17th inst. The report showed a most satisfactory condition—namely, that the financial position was absolutely sound, that there were 225 medical students on the books (there being 76 new entries this year), and that the arrangements for teaching and working were of the most complete kind. Additional interest was given to the meeting by the presence of the Home Secretary, the Right Hon. Henry Matthews, who spoke as a governor of the College and as a graduate of the University of London. He said that he should be loth to see any changes in that university which would lower the quality of the degrees, and

Digitized by Google

that there were certainly reasons against the multiplication of universities. These sentiments were supported by Sir James Sawyer, who presided, and were generally endorsed by the meeting.

Provincial Colleges and the London Higher Education Commission.

On the same afternoon a conference of representatives of the provincial university colleges of England and Wales was held in the Mason College, by the invitation of the Council and Academic Board, to consider the bearing upon those colleges of the recent report of the Royal Commission. A long discussion took place, and ultimately the following resolution was unanimously adopted: "That this meeting, composed of representatives of the University Colleges at Aberystwith, Bangor, Birmingham, Cardiff, Leeds, Newcastle-on-Tyne, Nottingham, and Sheffield, protests strongly against the adoption of any scheme for remodelling the existing University of London, which follows the lines of the report of the Royal Commission, on the ground that any such scheme invades the vested rights of the provincial colleges, and, by placing them at a disadvantage as compared with the metropolitan colleges, would, if carried into effect, operate seriously against their future progress and development." By another resolution a small committee was appointed "to approach the Lord President of the Council to request him to receive a deputation composed of representatives of the provincial university colleges, and to communicate his decision to the other colleges concerned; and, further, in the event of his consent being obtained, to make arrangements for the interview."

The National Temperance Congress.

The business of this Congress was inaugurated by a reception given by the mayor (Alderman Barron) on the 21st inst., the company numbering about four hundred. The proceedings were marked by much cordiality and satisfaction. The Bishop of London, as president of the Congress, delivered his inaugural address in the Town Hall to a large attendance. In a forcible and elaborate address he dwelt upon the advance made by the temperance movement, and stated that medical men had begun to restrict their recommendation of intoxicating liquors more and more year after year; the quantity that they allowed was becoming steadily less, and they have practically given up to the temperance side entirely the whole body of the young. A series of meetings throughout the district, and dealing with various aspects of the question, have been held, a temperance institute on a large scale opened, and organisations set on foot which promise to give a foundation for future working of this important aspect of social life.

The Scarlet Fever Epidemic.

The latest reports show that this epidemic has not gained in force during the last three weeks, the cases in each week being respectively 87, 85, and 85. On Saturday last the total number of cases in the hospital stood at 424. The death-rate remains very low. The deaths from the seven zymotic diseases numbered only 14 last week, as against 16 in the corresponding week of 1888.

Birmingham, Oct. 23rd.

NORTHERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENT.)

Newcastle.

IT appears from a statement in our local papers that the Executive Council of the late Jubilee announce a surplus in hand, after all known liabilities have been satisfied, of over £4000. This is very satisfactory, but I hardly think that the proposed handing over this important sum to the College of Physical Science here will be considered altogether free from objection. The College of Physical Science is a huge building, with a debt, a complete staff of professors, and a mere handful of students. Now, if some plan could be devised by which other and as useful and important institutions in the town could participate in this surplus, it would, I am sure, give more general satisfaction. I might mention, for instance, the College of Medicine, the Royal Infirmary, the Convalescent Home, and the minor medical charities, all doing good and useful work.—I see that the friendly societies of Hebburn-on-Tyne have held a meeting, and it has been mentioned by delegates that it would be desirable to have an infirmary of their own at Hebburn, instead of contributing annually £500 to the Newcastle Royal Infirmary. It is said that there are twenty-three friendly societies and workshops, all contributing to the Newcastle Infirmary. I fear the workmen will make a mistake if they carry out this suggestion. It would be all very well to have a small local hospital for surgical cases and accidents, but what is to become of the men when work becomes slack and they cannot subscribe to their proposed hospital? There is an immense advantage—of which the working classes get the most benefit—in keeping up a large central hospital like the Newcastle Royal Infirmary, where the nursing and other arrangements are very complete.

Death of Mr. William Cockcroft, M.R.C.S., Catterick.

I regret to notice the death of Mr. William Cockcroft, of Catterick, Yorkshire, which took place on the 13th inst. Mr. Cockcroft was a highly respected practitioner in the district for nearly fifty years, where he commenced after completing his medical education in Dublin. He was a hard worker in his profession up to about two years since, when his health completely broke down and he was compelled to retire.

Proposed Lunatic Asylum for Middlesbrough.

It was stated at a late meeting of the Middlesbrough Board of Guardians that the time had arrived when a lunatic asylum should be erected in Middlesbrough; at present it appears that there are at York 180 lunatics belonging to the Middlesbrough Union, and the guardians had received an intimation from York that the authorities there could not receive any more, while they were paying close upon £4000 a year for them.

Newcastle-on-Tyne, Oct. 22nd.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

EDINBURGH.

Opening of the Edinburgh University Union.

THE splendid buildings erected for the accommodation of the Edinburgh University students were finally thrown open on Saturday by the Chancellor of the University (Lord Justice General Inglis), and those interested had an opportunity of seeing what has been provided for their comfort and entertainment. So much has already been written about these buildings that it is now merely necessary to give a very brief description of the arrangements. There is a capital entrance hall, on either side of which is a writing-room and reference library, rooms which are also to be used for meetings of smaller University Societies which, according to the rules, may become affiliated with the Union. Beyond these rooms, and at a somewhat higher level, is a splendid luncheon and dining-room, in which a very considerable number of students can be served at once. From this is a stair leading to a smoking-room, in which are a couple of billiard tables. This room is well fitted up, and will certainly be a favourite resort for students in their leisure hours. On the top storey is a large hall, to be used as a general reading-room during the day and as a debating hall in the evening. At each side is a kind of strangers' gallery, and at the head of the room is a speaker's chair. This room is to be supplied with the various periodicals and journals, but it is anticipated that there will be the greatest run on general and medical literature for some time at least, as at present the medicals appear to be the most clubable men in the University. Passing from roof to basement, we come to a really good gymnasium, well fitted up with gymnastic apparatus, but sadly wanting in foils, masks, boxing-gloves, mattresses, and such-like movable "properties." Fencing is one of the best exercises that a man who is not regularly and actively engaged in physical exercise can have, and is specially well suited to meet the needs of a close student. *Verb. sap.* Here are a couple of ante-rooms, one of which is fitted with a shower-bath and with room for three or four warm baths. Outside these dressing-rooms are the lavatories, which are exceedingly well arranged. That the whole work has been done most thoroughly was the general opinion of those who took part in the opening ceremonial. The Chancellor of the Univer-

Digitized by Google

sity—who was accompanied to the platform by the Lord Rector (the Marquis of Lothian), Principal Sir William Muir, most of the medical and some of the other professors and lecturers, and a host of legal, civic, and general dignitaries—in declaring the Union buildings open, said that the promotion and encouragement of a more social and gregarious life among the students was by no means a new or crude idea. It formed the subject of serious and earnest consultation among the friends of the Scottish Universities of a former generation, now almost entirely passed away. He himself, twenty years ago, had advanced the opinion that if the students could be associated, not only in their studies, but also in their social hours and amusements, it would contribute largely and usefully to their educating one another, and that, in place of the dull life of the solitary student, there would grow up a life more cheerful and happy—a condition of the highest importance in our educational view, because the youthful mind is naturally joyous and impulsive, and whatever tends to unnecessary depression or sombre thought must impair its elasticity. He thought that the Union had done very wisely in inviting all who had been students in the past and are now members of the General Council to join the Union. It would indeed be very hard if former students, who have borne the burden and heat of the day in promoting its formation, should be denied all connexion with the full-fledged Union. One of the most striking features in the higher education of this country, in the present age, had been recognised—the larger sympathy and closer friendship between pupil and teacher, leading to their intimate association in sports and amusements, which may be enjoyed by both in common without the slightest derogation from the true character of the relations which must exist between them in hours of instruction; and the admission of professors and others in authority to the Union was conceived in a right spirit, and would probably lead to most useful and beneficial results. Lord Lothian, speaking on behalf of the students, thanked all who had helped in any degree and in any manner to bring about such a magnificent result. So far as he had seen, the Union met the utmost needs of the University, and would afford an opportunity for that social intercourse which did so much for student life. They would best show their thanks for the Union by making it what it was meant to be—an additional source of strength to the University to which they belonged, to the alma mater and most cherishing mother, to which anyone worth his salt must have the warmest devotion. Principal Sir William Muir also spoke; and later Lord Lothian caused some amusement by saying, in connexion with the passing of the Universities Bill, that from the professoriate point of view he had ample means—and they took care that he should have ample means—of knowing their desires; but the students had not the same opportunity of bringing their views before him. He did not say that they would have caused him to alter the character of the Bill, but it would have been a great satisfaction to him to know what their views were upon the great subjects that came under discussion in that Bill. In the evening there were great rejoicings, the torch-light procession as usual playing a prominent part in the proceedings.

New Assistant Surgeon in the Royal Infirmary.

There has been no lack of good candidates for the post of assistant surgeon in the infirmary. In addition to those already mentioned, Dr. Kenneth M. Douglas and Mr. H. A. Thomson were candidates. From what is already known of the work of the five men, any one of them might have been elected, and the infirmary would have been well served. The choice of the managers has fallen upon Mr. John Shaw M'Laren, M.A., M.B., F.R.C.S. Edin., at one time well known amongst the students as one of the best demonstrators in the "rooms." Mr. M'Laren was very strongly recommended as one able to bring to bear on his work all that anatomical knowledge, sound surgical training, and teaching capacity that the traditions of the Edinburgh University have associated with its surgical teachers.

The Triple Qualification.

At the quarterly examinations held in connexion with the Royal Colleges of Physicians and Surgeons, Edinburgh, and Faculty of Physicians and Surgeons, Glasgow, there were for the first examination sixty-five candidates, of whom thirty-four, or over 52 per cent., passed; for the second examination seventy-six candidates presented themselves, of whom thirty-three, or over 43 per cent., were successful; and for the final examination there were 101 candidates, of whom forty-six passed.

University of the Edinburgh Faculty of Medicine.

At the special final examinations, held early in October, forty-four of the candidates were successful, and will proceed to the degrees of M.B. and C.M. in due course.

Edinburgh, Oct. 22nd.

GLASGOW.

Cæsarean Section.

DR. MURDOCH CAMERON, obstetric physician to the Glasgow Maternity Hospital, has added a third successful case to his list of Cæsarean sections. The patient was rachitic, about 48 in. in height, and was sent from a neighbouring town, after being two days in labour. The operation was performed on Oct. 8th. The mother and child (female) are both doing well.

Glasgow, Oct. 22nd.

ABERDEEN.

Opening of the Winter Session at Marischal College.

NOMINALLY the winter session began on Tuesday, the 15th inst., but so few students put in an appearance on the first day that the introductory lectures were not delivered till the following day. The opening of the session found the Medical School without a professor of anatomy. Information had just been received by the Principal that Professor Struthers' resignation had been accepted, but no mention was made of a successor. Dr. Struthers at once offered to carry on the work of the anatomical department until his successor was appointed. This offer was accepted by the Senatus, and Dr. Struthers met the students on Friday the 18th. The large lecture-room was crowded, and the students received and welcomed back their old teacher with tremendous cheering. He said: "A short time ago I was your professor, but now I am only your teacher temporarily." Since they last met, he said, he had had only four days' holiday, but he thought he had still vitality enough left in him to carry on the work for a fortnight or so. Most of the professors delivered more or less special introductory lectures. Professor Hamilton chose for his text "Some of the Diseases Common to Man and the Lower Animals." He referred to his Introductory Lecture last year on Pleuro-pneumonia. In it he strongly advocated the establishment of experimental stations with the view of studying the pathology and preventive treatment of the malady. His advice has been taken by the local authority of Fife, and stations have also been established in Australia. He said this was a step in the right direction. In Australia immense saving to cattle-owners has followed the introduction of inoculation. The present system of attempting to eradicate the disease by the slaughter of the whole herd where the disease appeared has not proved a success. Compulsory slaughter, he said, may stay the progress of the scourge for a time; but it is at the best an artificial and clumsy remedy. What we want to know is, Can the proceeding (inoculation) be so perfected as to be free from danger, and yet so efficacious that it will preserve animals through a certain number of years from infection? If so, then we would have some sort of solid basis to found compulsory legislation upon, such as that which now prevails against small-pox. Concluding his remarks on this subject, Professor Hamilton said: "A most interesting question arising out of the study of pleuro-pneumonia in cattle is its relationship to pleuro-pneumonia in man. The disease as it occurs in man is distinctly infectious; but whether it is alike in its causation with the infectious pleuro-pneumonia of cattle remains unsettled." The remainder of the lecture was taken up with the consideration of tuberculosis, "wooden tongue," epidemic sore-throat, &c. Professor Smith Shand first spoke of the extension of the University buildings now going on. He then referred to the resignation of Professor Struthers as "another notable event" which had taken place during the past year. He said: "Dr. Struthers has retired after a professional life devoted to scientific teaching and research. During his *régime* the advance and prosperity of the Medical School have been very marked and greatly due to his exertions and influence. An able teacher, an excellent man of business, an authority on all matters pertaining to university and medical legislation, a man possessed of great energy and

Digitized by Google

strong traits of character, his resignation leaves a blank in the professoriate which it will be difficult to fill. Let us hope that relief from the routine of academic work and teaching will so restore his health that he may enjoy many years of learned leisure." Dr. Smith Shand then spoke of the passing of the Universities Bill, and the great changes that would probably take place in the curricula of the different faculties. He said: "Recently the medical journals have been filled with the contending views of Mr. Wheelhouse of Leeds, the present President of the British Medical Association, who takes the purely practical side of medical education, and argues in favour of apprenticeships; and of Professor Gairdner of Glasgow and of Dr. Clifford Allbutt, who are strongly in favour of scientific and university training. I myself thoroughly agree with the latter system as taught in our Scotch schools, and consider that the wider scientific training of the University, together with due attendance on dispensary and hospital practice, constitute the best means of qualifying the student for the future business of his life. A return to the apprenticeship system would, I consider, be a most retrograde step." Dr. Smith Shand said the great difficulty that had to be contended with was the overloading of the scientific portion of the curriculum to the detriment of the practical portion. The remedy for this which he most favours is to extend the curriculum so that it shall embrace five years of professional study. Professor Cash spoke of the position of his subject, "Materia Medica in Medical Education," and pointed out that the designation of the chair was misleading or insufficient, as it did not indicate that pharmacology and therapeutics—two of the most important and direct applications of science to practical medicine—were taught as well as pure materia medica. He pointed out that the scope of the subjects to be covered in the systematic lectures was very extensive, and argued that if any redistribution of subjects were made in the future a certain part of pure materia medica should be relegated to the departments of chemistry and botany, and this would leave time for the remaining portion of materia medica, as well as therapeutics and pharmacology, including toxicology (except from its medico-legal aspects), to be exhaustively dealt with by the professor of materia medica.

Health of the City.

In his report for September, Dr. Hay states that the number of deaths in the city during the month was 171, which is at the rate of 17·13 per 1000. During September twenty cases of measles were reported, as against seventy-three for August. During the epidemic of measles, which has now exhausted itself, 2000 cases were reported. The city is now threatened with an epidemic of scarlet fever. In September seven cases were reported, but the disease, owing to the carelessness of those affected, is making considerable progress. Dr. Hay has issued a special appeal to the public to exercise every precaution and carry out the printed instructions as to isolation and disinfection.

Aberdeen, Oct. 23rd.

DUBLIN.

(FROM OUR OWN CORRESPONDENT.)

Royal University of Dublin.

A MEETING of Convocation was to have been held on Tuesday, the 22nd inst., but as a quorum did not attend no business could be transacted. It was intended to submit the report from the annual committee to the meeting. The committee stated that a commencement had been made of the University library and museum, and they hoped that immediate steps would be taken to secure to members of the University the privilege of making use of it. The museums illustrative of physical science, biology, and pathology are not open to members of the University, and to exclude students from the advantage of access to collections containing valuable and in some places unique specimens, appears to be a policy of doubtful expediency. Under the statutes in force up to the present year, Fellowships becoming vacant by death or resignation in and after 1889 could only be filled up by competitive examination among the graduates of the University; but the committee have learned that these statutes have been altered and new ones substituted, from which the provisions for competition have disappeared. They regard it, they say, as a matter gravely affecting the well-being of the University and the interests of its graduates that the rich prizes offered for competition, under the provisions of the charter and the sanction of the royal statutes, should have been withdrawn, and that in the very year when, for the first time, they were to have been attainable. A meeting of the University for the purpose of conferring degrees will take place on Monday next, the 28th inst. It is expected that the Chancellor of the University, the Marquis of Dufferin, will preside.

College of Physicians in Ireland.

The Fellows on St. Luke's Day duly elected Dr. Atthill President, and also representative of the College on the General Medical Council for the ensuing year. At the same meeting the Fellowship was conferred upon Dr. Henry C. Tweedy. Last week Dr. Aquilla Smith was presented with his portrait by the Fellows of the College, not only as a token of esteem, but also as a recognition of his services to the College as representative of the College on the General Medical Council. It may be added that the cost of the portrait was subscribed for exclusively by the Fellows of the College, and that the artist—Mr. Catterson Smith—has produced an admirable likeness.

Royal Academy of Medicine in Ireland.

From the report for the past year of the General Council it appears that the number of Fellows is 244, or an increase of twenty-one over the previous session, and that the total amount invested on behalf of the Academy now stands at close on £600. A resolution having been adopted last year approving of the proposal that some member of the profession should be invited to address the Fellows and Members on some branch of medicine, it has been arranged that Professor Purser shall deliver a lecture during the present session, for a remuneration of twenty-five guineas. It has been suggested that the Council should sanction the formation of a committee in connexion with the anatomical section, for the purpose of extending the method of collective investigation to anatomical research in the schools of Ireland, and the Council regard the scheme as one of the modes in which the Academy may aid in the development of medical science in this country. The election of office bearers will take place on Friday next, the 25th inst., and there will be contests for seats on the Council in every section, with the exception of the medical section.

Rotundo Lying-in Hospital, Dublin.

Dr. Macan will shortly vacate the mastership of this institution, and an election for his successor will take place in a couple of weeks. There are numerous candidates for the post, the emoluments of which are about £1000 a year, and the appointment is tenable for seven years. It is generally believed that Dr. W. J. Smyly will be selected. The mastership of the Coombe Lying-in Hospital will also shortly be vacant, and it is expected that the appointment will lie between Mr. Colclough Hoey and Dr. F. Kidd, both having acted as assistant masters to the institution.

Jervis-street Hospital, Dublin.

The introductory address at the opening of the winter session will be delivered on the 1st prox. by Mr. Austin Meldon, President of the Royal College of Surgeons in Ireland. Mr. Meldon has selected for his address the subject of "Pasteur and Hydrophobia."

Galway County Infirmary.

Mr. Robinson and Dr. Browne, Local Government Board Inspectors, by warrant of the Lord Justices, held an inquiry last week in the County Court-house into the condition of the Galway County Infirmary. The following were the points upon which evidence were particularly taken:—(1) The present state of the County Galway Infirmary in relation to the funds available for its support, and the general management of the institution; (2) whether it is expedient that the said infirmary should be converted into a public hospital; (3) whether it is desirable that the county of the town of Galway should be required to contribute towards the cost of maintenance of the infirmary, and, if so, to what extent; (4) in the event of such changes being considered advisable, what alteration would thereby become necessary in regard to the constitution of the governing body of the institution; and (5) what arrangements would seem to be expedient with respect to the future admission of patients, the inspection of the institution, and

Digitized by Google

the auditing of the accounts of the governing body thereof. The infirmary had a full staff of nurses, a surgeon, and two resident pupils. Paid patients were admitted at various rates, varying from tenpence to two shillings per day. There were sixty-one beds. Evidence was given showing the necessity of converting the institution into a public hospital, and Colonel O'Hara, one of the governors, propounded a scheme for the future working of the infirmary. He would allow the ratepayers a representative, while the election of a surgeon should be vested in the Lord-Lieutenant, and not in the governors. He would admit, largely, paying patients and all accident cases at once, though most accident cases should also be paying. Some further evidence having been tendered, the inquiry closed.

The Second Professional Examination under the Conjoint Scheme of the Colleges of Physicians and Surgeons was held last week, and I hear that out of fifty candidates only nineteen passed.

Three Dublin practitioners are at present ill from fever—viz., Messrs. Horne, Ashe, and Auchinleck. Two of the cases are typhoid and the third typhus.

An election for two members of Council of the Royal College of Surgeons took place to-day, with the result that Dr. Kidd and Mr. H. R. Swanzy were returned.

Dublin, Oct. 22nd.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Action of Iodide of Potassium on the Heart.

As whatever emanates from the pen of Professor Germain Sée is always interesting I make no apology in offering to your readers the following abstract from the very important communication he made to the Academy of Medicine on the 8th inst. on the action of iodide of potassium on the heart. He began with the remark that it is not sufficient to affirm that iodide of potassium has a tonic action on the heart, but it must be proved that it is so and how or why it is so. This the learned professor had endeavoured to resolve by experiments in the laboratory and by clinical observation. In conjunction with Dr. Lapicque (his *chef de clinique*) his researches were first directed towards the modifications of the blood pressure under the influence of the iodides of potassium and of sodium, to ascertain whether these salts produced a vaso-constriction or a vaso-dilatation, and also the conditions of the mode of their action. This was done by injecting into the saphenous vein of numerous dogs solutions of the iodide of potassium or of sodium in the proportion of one to ten parts. The dogs were feebly curarised, and a registering manometer indicated the pressure in the carotid or in the femoral artery. It is known that the salts of potash excite the heart and the vaso-constrictor nerves, and raise the blood-pressure. Nothing of the kind takes place with the salts of soda. M. Sée had first verified that the radicle potassium conferred on its iodide the properties of the salts of potash. The following were the very interesting results obtained. When iodide of potassium or iodide of sodium is injected into the blood phenomena are observed which present two distinct phases. M. Sée designates the first "the phase of the alkali," and the second "the phase of the iodine." When the iodide of potassium is employed the phase of the alkali is distinctly characterised. The heart's beat is accelerated, the pressure raised, and the tracings present great oscillations, which are slow and regular. When the iodide of sodium is employed, the phase of the alkali is indicated by a very slight elevation of the pressure, slowing of the action of the heart, with occasional intermissions. On the contrary, the phase of the iodine corresponds with the injection of either of the two salts, and it is indicated by the pressure, which descends slowly, in a continued manner, and by the action of the heart, which is accelerated. M. Sée offers in explanation of this similitude that the iodide of potassium is decomposed, that the potassium is eliminated, and that the iodine is thus found in the blood, combined with the sodium, whatever be the iodide primarily injected. However that may be, Professor Sée's experiments seem to show that the iodide of potassium first determines phenomena of excitation, with the action of the heart accelerated, an elevated pressure, a manifest vaso-constriction; then follows vaso-dilatation, with low pressure, which is also determined by the iodide of sodium. In the vaso-constriction, with elevation of pressure, and the strengthening of the heart due to the potassium, the vaso-dilatation and lowering of the pressure due to the iodine, we have, says M. Sée, the explanation of the effects of the powerful action of the iodide of potassium. The vaso-dilatation explains the hyperæmia of the bronchial mucous membrane and the hyper-secretion which results from this drug, and which is so useful to asthmatics for getting rid of viscous secretions. It explains the pulmonary hyperæmia which results from the venous stagnation in cardiac subjects. It also explains the anti-dyspnœic power of the iodide of potassium in facilitating the circulation in the medulla, and consequently restoring it to its normal functional activity. Immediately the paroxysmal or continued dyspnœa, the fits of suffocation, &c., completely disappear. The vaso-dilatation finally explains how the heart becomes freed from the obstacles which the tonicity of the arterial vessels presents to it, how the coronary circulation becomes more free, and how the heart becomes reinforced and beats with energy. On the other hand, iodide of potassium primarily strengthens the heart and the pressure. Hence M. Sée, comparing its action with that of digitalis, and studying the toxicity of the salts of potash, so exaggerated by physicians, has given it the name of "digitalic poison"—that is to say, beneficial. It results from these considerations that iodide of potassium is applicable to the greater part of the diseases of the heart and of the coronary vessels. Useful in the most diverse lesions, M. Sée would condemn it only when it determines hæmorrhages or permanent gastric iodism. It is not only useful against dyspnœa, it is still more so in many other cases, and M. Sée explains how and why it is so. Iodine reduces the fatty element in fatty degeneration of the heart. In fibro-adipose degenerations, in sclerosis, one cannot expect the reduction of the transformed tissues, but the muscular fibres which have quickened their circulation remain and are consequently improved in their function, whence the indication for iodide of potassium in all cases of degeneration. If the heart be weakened from overwork, or be in a state of asystolism, iodide of potassium renovates the weakened or distended tissues of the heart. If the left ventricle be hypertophied, the most that the drug can do is to render the cardiac circulation more active; it cannot be injurious, as it does not reduce the muscular fibre. In coronary sclerosis (angina pectoris) it is useful in dilating the coronary vessels that have remained free and healthy; but this is not an arterial medicament in the denutritive sense. In cardialgia (false angina pectoris), where the pains are so severe, where the respiration is polypnœic, it has incontestable advantages combined with antipyrin or with inhalations of the vapours of pyridine. In Basedow's disease, or where there already exists a morbid vaso-dilatation, the iodide of potassium will be useless, or even dangerous. On the contrary, it is in aneurysm of the aorta that it succeeds, although it is not by producing the coagulation of the blood, as is generally believed. But it is here, in particular, that M. Sée objects to the use of iodide of sodium, the employment of which nothing can justify.

Paris, Oct. 22nd.

Obituary.

SAMUEL OSBORNE HABERSHON, M.D. LOND., F.R.C.P.

A BRIEF NOTICE of the death of this able and eminent physician appeared in our issue of Aug. 31st, and we now append a review of his life.

Dr. Samuel Osborne Habershon, who was born at Rotherham in 1825, was a descendant of the Yorkshire branch of an old Lancashire family, whose seat, Habergham Eaves, was in the village of Habergham, or Habersham, near Burnley. The older name of Habersham is still retained by the American descendants of the same family, whose ancestors went over with Whitefield, and were among the earliest settlers in the State of Georgia, and contributed the first governor of the colony, and subsequently a post-master-general in Washington's Cabinet. Dr. Habershon was educated at Brampton, near Watt, and at Ongar, Essex. He

Digitized by Google

came up to London in 1840, and at this early age commenced the study of medicine with the assiduity and earnestness which characterised the whole of his after career. Although present at the introductory lecture delivered by the late Dr. Addison at Guy's Hospital in 1840, he did not enter there as a student until two years later. He became, however, a pupil of the late Mr. Ebenezer Pye-Smith, of Billiter-square, City, and, meanwhile, attended lectures on botany at the London Hospital, where he gained the first prize, a silver medal, at the end of the session. His career at Guy's dates from the year 1842, and his record, both at that hospital and at the University of London, was one of continuous and brilliant distinction. Prizes in chemistry and anatomy were awarded him at Guy's in 1843 and 1845, as was also the first prize in chemistry at the matriculation examination of the University of London in 1844. In the first M.B. examination in 1846 he was first in anatomy, in materia medica, and in chemistry, obtaining three gold medals and two exhibitions. In 1848, in the second M.B. he obtained the first place in medicine with a gold medal and scholarship, and the first place in physiology with a gold medal. This uninterrupted success speedily brought him into notice at his hospital, and he was in the following year, 1849, appointed demonstrator of anatomy and tutor. In 1851 Dr. Habershon took his M.D. degree, and became lecturer at Guy's on comparative anatomy, and also gave microscopical demonstrations. These posts he continued to hold until 1853, when he was appointed demonstrator of morbid anatomy, curator of the museum, and lecturer on pathology. In 1854 he was appointed assistant physician to Guy's Hospital, and in 1856 he relinquished the posts he already held for the chair of materia medica. At the same time, in consequence of Dr. Addison's death, he took charge of certain beds in Philip ward. In 1864 he superintended the Skin Department and gave demonstrations, and in 1866 was elected full physician, becoming senior physician in 1873. In this year he exchanged the lectureship on materia medica for that on the principles and practice of medicine, which he held until the year 1877. His career at Guy's Hospital, so distinguished and honourable, was, however, destined to be cut short by circumstances altogether unforeseen. In November, 1879, it became apparent to the medical staff that the new departure in the system of nursing was seriously interfering with the welfare and treatment of their patients. A remonstrance with the governing body led to serious conflict, which was further embittered by a widespread discussion in the public press. Regardless of the opinion of their medical staff, who were qualified by their technical knowledge and daily experience in the wards to be the best judges in the matter, the governing body practically upheld the innovations. As a final result of the prolonged controversy, the resignations of the senior physician and surgeon were demanded, and although this demand was subsequently withdrawn, yet Dr. Habershon and the late Mr. Cooper Forster felt strongly that their continuance in office was not consistent with their personal views of professional dignity and honour. They consequently sent in their resignations in November, 1880, which were accepted. Thus ended for Dr. Habershon a connexion of nearly forty years with Guy's Hospital—a connexion which included the best years of an active life and much arduous and brilliant work. That his action and that of his colleague, Mr. Cooper Forster, was not without large professional support was sufficiently proved by the presentation of a substantial testimonial to each of these gentlemen on the part of old Guy's men and numerous other friends. Whilst deeply regretting the serious check thus inflicted on the progress and prosperity of a great hospital and medical school, it must be recognised that other institutions have profited by the experience, and have safeguarded themselves from a similar catastrophe by giving adequate representation to the views of the medical staff in their governing bodies. It is still further to be regretted that the suggestion made some time since, that Dr. Habershon and Mr. Cooper Forster should be placed on the consulting staff of the hospital, was not carried out—a compliment which would have been not only worthy of the recipients, but graceful on the part of the donors.

In addition to his university degree, Dr. Habershon in 1848 became qualified as Member of the Royal College of Surgeons, England, and a Licentiate of the Apothecaries' Hall. In 1851 he became Member of the Royal College of Physicians and Fellow in 1856. Subsequently he was appointed Examiner in Materia Medica at that College, and one of the Council in 1869; in 1874 and 1875, Censor; in 1876, Lumleian lecturer; in 1876 to 1877, Examiner in Medicine; 1877-8-9, member of the Council; Harveian Orator in 1883; Senior Censor in 1885; and Vice-president in 1887.

Dr. Habershon was physician to the City Dispensary in 1852, but resigned eighteen months afterwards on account of his appointment to Guy's Hospital. In 1862 he became physician to the Star Life Assurance Society, and in 1863 consulting physician to the London City Mission, both of which posts he continued to hold until his death. At the medical societies Dr. Habershon took a prominent position. He delivered the oration at the Medical Society in 1863, the Lettsomian lectures at the same Society in 1872, and was elected president in 1873. He became president of the Metropolitan Counties Branch of the British Medical Association in 1880.

During the many years of Dr. Habershon's intimate association with Guy's Hospital, in each and every capacity, whether as student, teacher, or physician, he was especially distinguished by the conscientiousness and earnestness, as well as by the ability and success, with which he fulfilled the duties that devolved upon him. One who was his colleague up to the termination of his connexion with Guy's, and who valued him as a friend during a period of nearly thirty years, and until his death, writes as follows: "I cannot express my own sorrow, nor my sense of the loss the profession and the public generally have sustained by the death of my dear friend Dr. Habershon. From intimate and long acquaintance and association with him, both as a colleague at Guy's Hospital and in private practice, I learnt to appreciate and to value his character more highly than I can say. Genuine, upright, honest, kind, and considerate, his personal qualifications endeared him to his friends and patients; while his ability, experience, and careful and thorough method of examination secured for him the confidence of his professional allies in his judgment and advice."

Dr. Habershon's position in the profession was the outcome of his own exertions and hard work. Coming up to London as he did when a mere boy, without influence or medical friends, his studious habits and power of application to work soon gained for him a thorough mastery of each branch of his profession, resulting, as we have seen, in an exceptionally distinguished career. The early years of his connexion with Guy's Hospital as a teacher were mainly spent in the anatomical school, the post-mortem room, and the museum. Such a training made use of by a man of conspicuous ability, stood him in good stead in after life. His beautiful and careful dissections, and excellent knowledge of anatomy, his many years of pathological research, formed the basis of much good and sound work. As a writer the books and numerous papers from his pen are of much value, recording as they do the result of years of careful clinical observation and experience. The Guy's Hospital Reports, from the year 1855 to 1872, contain a series of twenty-eight papers written by him. Other articles are published in the Medico-Chirurgical Society's Transactions, THE LANCET, and other medical journals. His most important contributions, however, to medical literature, and those by which his reputation was chiefly made, are: "On Diseases of the Abdomen," published first in 1857 (fourth edition, 1888—also published in America); "On Diseases of the Stomach" (third edition, 1879); "On Some Diseases of the Liver" (Lettsomian Lectures, 1872); "On the Pathology of the Pneumogastric Nerve" (Lumleian Lectures, 1876; translated into Italian, 1879); "On the Injurious Effects of Mercury in Disease."

Widely known as an authority on abdominal disease, Dr. Habershon had an extensive practice. In his methods of treatment he was gentle and opposed to strong or heroic measures, and yet in exceptional cases he was not slow to recommend them, and it is worthy of record that he was the first in England to propose the operation of gastrostomy for stricture of the œsophagus, which was performed, at his suggestion, upon a patient of his by the late Mr. Cooper Forster in 1858. The operation, of course, has since been frequently performed with success in other cases. Though by nature quiet and retiring, Dr. Habershon's influence was a strong one. In the councils of the College of Physicians his opinions were always listened to with respect, and his influence carried weight. Sir William Jenner, during whose presidency he held several of the

Digitized by Google

highest offices, pays the following tribute to his memory: "Dr. Habershon's death is a great loss to the profession. The College of Physicians had no Fellow more sensible, more worthy, or more honourable. As a consultant his professional brethren felt they could repose full confidence in his judgment and in the uprightness of his conduct, while the public justly trusted his ability, skill, and probity."

A man of strong religious convictions, Dr. Habershon engaged in many works of philanthropic interest. As far back as the year 1849 he assisted the Darby-street Ragged School, and afterwards became its valued and devoted superintendent. Later, when he moved from the City to the West-end, he did not relax his useful efforts, and continued almost up to the time of his death in Christian work amongst the poor of his neighbourhood. Even where he was unable to give his personal services he was a generous supporter and staunch friend of many charitable institutions. But his influence for good was also prominently felt by those with whom he came in contact in the midst of his public and professional duties. The wisdom and kindliness of his advice, the force of his example, and his consistent fearless and honourable character were universally recognised. "He was always a very great favourite with the students of his hospital, and was looked up to as a careful and painstaking clinical teacher, and on going round the wards he had always a large and appreciative following. Very many of them esteemed and loved him, because they felt that he had always their best interests at heart. And when, as one of the originators of the Christian Medical Association, he invited to his house on Sunday afternoons the students of Guy's and St. Thomas's Hospitals, they were so impressed with his sincere and heartfelt words, so free from anything like cant, that they could not but feel that he was a true friend interested in their welfare for this world and the next." Such at least is the opinion of one who, as a pupil, knew him well in those days, and continued throughout his life to be a warm and sincere friend.

Dr. Habershon was never a robust man, but, with the exception of one serious illness some years ago, enjoyed good health until within eighteen months of his death. Several times during last year he suffered from severe dyspeptic attacks, but the cause of his malady was not suspected until he was prostrated in November by severe hæmatemesis. During this illness he was attended by Sir William Jenner, in conjunction with Dr. Gilbart-Smith and his son Dr. Herbert Habershon. Recovering in great measure, he resumed his work, but the death of Mrs. Habershon in April, and the mental shock consequent upon it, undermined his health and resulted in a return of his disease. Hæmorrhage from the stomach again appeared on July 9th, and he was again confined to his bed. Repeated hæmorrhages reduced his strength, and in spite of the skill and unremitting care of his medical friends and advisers, Dr. Andrew, Sir A. Garrod, Dr. Gilbart-Smith, and the nursing of his son, he died on Aug. 22nd at his residence in Brook-street of simple ulceration of the stomach. It is not a little remarkable that he should have thus succumbed to a disease upon which he was undoubtedly one of the first authorities.

Dr. Habershon leaves a son and three daughters.

DR. PHILIPPE RICORD.

ONE of the most illustrious characters of the age has just passed away in the person of Dr. Philippe Ricord, who died on the 22nd inst. after a few days' illness of pneumonia. He was born at Baltimore on Dec. 10th, 1800. At the age of twenty years Philippe Ricord arrived in Paris, was soon after admitted to the Internat, followed the lectures of Dupuytren and of Lisfranc, and obtained the Doctorate of the Faculty of Medicine in 1826. Being in poor circumstances, and, as he found it hard to live in Paris, he went to the provinces, whence, after having had a successful practice, he returned to Paris in 1888. He immediately entered the Concours for the Bureau Central of the hospitals. He was admitted first on the list, and was attached to the Pitié Hospital as surgeon, where during two years he lived with the produce of lectures for which he was paid. Three years later (in 1831) he was appointed principal medical officer of the Hôpital Midi, which is reserved for the treatment of venereal affections in the male sex. From this time a promising career was opened to him. He soon acquired a world-wide reputation on the subject of venereal diseases, and he was always considered the highest authority on that class of affections. His private consultations were very remarkable. He had several waiting-rooms in his house for the reception of the different categories of patients who called on him. He had a clever footman, who at first sight knew how to classify the clients. There were waiting-rooms reserved for ladies apart from those for gentlemen. Ricord was of a very generous turn of mind, for he not only gave his services gratuitously to those who could not afford to pay his fee, but he would help them if they were in need. He was courteous and affable, and full of wit, and had an encouraging word for each of his patients, whatever his position in life. He was a man of strong build, and, notwithstanding his advanced years, was very vigorous until quite lately, when his strong constitution began to give way, but his mental faculties were sound till near the last moments of his life. He was the Doyen of the Academy of Medicine, to which he was elected member in 1850, and of which he was once elected its President. Ricord received many honours.. In 1860 he was promoted to the dignity of Commander of the Legion of Honour, and in June, 1871, M. Thiers conferred on him the grade of Grand Officer of the Legion of Honour in recognition of his services at the Ambulances during the siege of Paris. He had received more than two hundred decorations from different foreign Governments throughout the world. It was in fulfilling his duty as a loyal citizen that he contracted the malady which proved fatal to him. On the day of the general elections, on the 6th of October, he came to Paris from Versailles, where he generally spent his summer, in order to deposit his vote in the urn, and immediately started to return to Versailles, but being late for the train he waited an hour at the station for the next train. In thus waiting at the station he took a cold and had to return to his home in Paris. He then had symptoms of pulmonary congestion, which, however, subsided; when on Thursday week last he went down to his garden, and during the night was seized with symptoms of pneumonia, which carried him off on the morning of the 22nd inst. at three o'clock. He was most assiduously attended by Drs. Potain and Bouchut and others of his medical friends and former pupils. For two or three days before his death his flagging strength was kept up by inhalations of oxygen. During the course of Monday alone the patient was made to inhale 800 litres of oxygen. Until seven o'clock in the evening he had full possession of his mental faculties, and was able now and then to speak to Dr. Potain, who was by his bedside, but from that hour he never uttered a word, and expired at three o'clock on Tuesday morning. His funeral takes place to-day (Saturday) at Père la Chaise.

1828

DR. CHARLES ROYSTON.

WE regret to have to record the death, at his residence in Bayswater, of Dr. Charles Royston, under circumstances to a peculiarly sad and painful nature. The deceased, who was about to marry again, was found dead in his bed on the morning of the 15th inst., and at the subsequent inquest the jury returned a verdict, "That the deceased died from an overdose of prussic acid self-administered while suffering from intense mental excitement and severe physical suffering." We are informed that Dr. Royston had of late been passing through a condition of mind in which excitement alternated with fits of depression, in addition to which he had, for some weeks past, although unknown to his relations, been a victim to insomnia. The post-mortem examination showed that the deceased suffered from an abscess on the gall bladder, the pain from which undoubtedly induced a condition of mind which rendered him unable to face trivial worries, which at other times he would have lightly dismissed. A solemn funeral service was held in St. Stephen's Church, Westbourne Park, and the signs of mourning were general throughout the parish, in which the deceased had been a long and respected resident.

METROPOLITAN POLICE SURGEONS' ASSOCIATION. The annual dinner of this Association will take place at the Criterion Restaurant on Thursday, Nov. 14th, at 7 o'clock.

Medical News.

UNIVERSITY OF CAMBRIDGE.—At a congregation, held on the 17th inst., the following degrees were conferred:

Bachelors of Medicine.—Eustace John Parke Olive, St. John's; Eustace Henry Lipscomb, Gonville and Caius; Albert Charles Elsmore, Christ's; Arthur Court, Cavendish Hostel.

Bachelor of Surgery.—Edward Henry Douty, King's.

The Examiners in State Medicine have issued the following list of those examined and approved for both parts of the examination, who are entitled to a diploma certifying to their competent knowledge of what is required for the duties of a medical officer of health. All those approved are on the Medical Register of the United Kingdom:—

F. E. Adams, A. Ambrose, A. R. S. Anderson, C. J. Ayres, G. R. Beardmore, J. T. Calvert, J. W. Campbell, A. K. Chalmers, E. H. Colbeck, H. D. S. Compigné, W. Cotton, A. M. Davies, U. K. Dutt, J. H. Garrett, H. C. M. Gibson, J. Glaister, J. E. Gould, W. Gruggen, W. Jackson, J. R. Kaye, C. S. Kilner, R. Laing, J. Loane, C. R. Macdonald, W. A. Macnaughton, R. M'Niell, J. Nall, R. L. Roberts, D. Roxburgh, A. F. Street, J. Taylor, G. T. Thomas, G. M. Thompson, C. B. Voisey, G. H. Weston.

Dr. Norman Moore, of St. Catharine's College, has been appointed Assessor to the Regius Professor of Physic.

Dr. W. M. Orr, of London, was appointed an examiner in Medicine, and, in consequence of the large number of candidates for the examination in State Medicine, Dr. Carpenter, of London, and Mr. George Turner, lecturer on hygiene at Guy's Hospital, London, were appointed additional examiners.

UNIVERSITY OF GLASGOW.—The following gentlemen have passed the First Professional Examination for the degrees of M.B. and C.M:—

James Alexander Aitken, Robert Hugh Allen, Thomas Barrowman, John James Boyd, Wm. Brodie Brodie, William Mackenzie Brown, Walter Isaac Buchanan, Archibald Prentice Campbell, Jas. Carslaw, M.A., David Charters, Charles Edward Cochrane, James Cochrane, Henry Adolf Cohrs, Alex. Dalrymple Cuthbert, Henry Davies, David Alexander Dewar, Archd. Smith Dick, John Donald, Alexander Edwards, Alex. Robert Ferguson, Andrew Findlay, Alfred Forrest, John James Fraser, Wm. Fulton, Wm. Sprott, Alex. Galt, Thomas Adams Stewart Gibb, Charles L. S. Gibson, David Wyllie Girvan, Daniel M'Intyre Glen, Robert Guy, Walter Buchanan Hastings, Ernst Denny Scott Heyliger, Campbell Highet, James Hogg, John Lindsay Howie, James Jack, John Kennedy, George Lawson Kerr, Hugh Kerr, M.A., Thomas Kirkwood, M.A., Thomas Donald Laird, David Lewis, John Lindsay, William Lowe, James Marr, Robert M'Farlane Marshall, David Ramsay Miller, James Moffat, James Donald Rae Monro, John Morton, William M'Niven Muat, Alex. Christie M'Arthur, Colin Campbell M'Call, Arthur Wellesley M'Clelland, Alex. Hutchison M'Cracken, Duncan M'Donald, John M'Donald, M.A., Malcolm Macnicol, M.A., Alex. Stewart M'Pherson, Peter Carmichael M'Robert, William M'Walter, Robert E. Newton, John Paterson, M.A., John Paxton, James Pettigrew, Wm. John Richard, M.A., James Jenkins Robb, James Bryce Robertson, Leonard Alfred Rowden, Thos. Leadbetter Shields, Francis Small, George Smith, M.A., James Smyth, John Barr Stevens, Nathaniel Stevenson, M.A., Charles Stewart, William Stiell, David Robert Thomson Strong, Robert Taylor, John Hammond Teacher, M.A., David Wallace, Andrew Wauchope, Hope Wellis, Charles Wilson, Robert Wilson, Alfred Alexander Young, M.A., Jas. Murray Young, John Cameron Young, William Semple Young.

The following have passed the Second Professional Examination:—

William H. M. Alexander, William Clachan Allardice, William Anderson, Robt. Bishop, Peter Otho Watkin Browne, Adam Guthrie Burrell, David Birrell Campbell, Niel Campbell, Andrew Cluckie, Charles Edward Cochrane, Robert Cochrane, Alex. Baillie Craig, John Alexander Creighton, Hugh Colligan Donald, James Gray Duncanson, Alfred Ernest Evans, John Falconer, William B. O. Ferguson, David Frame, M.A., Thos. James Freeman, Hugh Galt, Edwin Arthur Gibson, John Green, David Harries, Wm. Sandilands Harrison, Robert Home Henderson, William Moffat Holmes, Robt. King Howat, William Jackson, Robert James, David Clark Laird, Peter Alexander Laird, David Lamb, John Wm. Logie, Robert Alex. E. Lowry, Samuel T. M'Clintock Lowry, Robert Mortimer Malcolm, John Miller, Robert Moir, Percy Hope Murray, William Murray, Robert M'Ghie, John M'Gregor, Charles Hugh M'Ilraith, M.A., Alexander L. M'Leod, M.A., Robert Wm. Nairn, James Henderson Naismith, Gilbert Park, Robert Ramsey, Archibald George Saunders, David Smith, Maurice Tancred Stack, Geo. Clark Stewart, Geo. Mervyn Sydenham, Daniel M. Taylor, M.A., William Risk Thomson, M.A., James Todd, Ebenezer Turner, Wm. Watson, Hope Wellis, John Whitehouse, William Young, John Yuill.

The following have passed the Third Professional Examination, including, in the cases marked with asterisks, the subject of Pathology:—

Peter Henderson Abercrombie, John Adam, John Wilson Adam, *Alexander Percy Agnew, *James Alexander, *Thomas Primrose Anderson, James Barr, Robert Burns, William Butler, *Matthew Cameron, James Hamilton Campbell, *John Monro Campbell, Archibald Chalmers, M.A., *Jas. Chalmers, Jas. Easton Chalmers, John Cochrane, Samuel Cockburn, James Cordiner, M.A., William Craik, William Crichton, Peter Drummond, M.A., *George Henry Edington, *David H. Fotheringham, M.A., *James Fisher Frew, Robert Girdwood, Andrew Goldie, *Charles Herbert Hall, *James Hill, Anthony Inglis, George Scott Jackson, *Gilbert Petgrave Johnson, James Kirkwood, *John Lithgow, Matthew Lochhead, *James Rowatt Logan, *George Agnew Main, William Mason, John Wilson Mathie, *Alexander Goodsir Mowat, M.A., *James Muir, *David M'Donald, *Wm. Dove Macfarlane, Duncan Otto M'Gregor, Hugh Macintyre, Neil Macintyre, *Daniel M'Kenzie, John Norman MacLeod, M.A., *James Gibson M'Naught, M.A., James Niven, William Park (Beith), *William Park (Kilmarnock), *Peter Paterson, Edward Ley Paton, M.A., *John Pollock, Brownlow Riddell, William Roberton, Alex. Marshall Roy, Charles Francis Scott, *Archibald Shaw, *William M'Gill Smith, Rodk. Tate Sutherland, Lewis Dunbar Temple, *John M'Donald Vallance, *James Sim Wallace, B.Sc., Wm. Thompson Merry Wallace, Andrew Watson, John Watt, *Alex. David Wilson, James Alex. Wilson, *Andrew Wylie, Hugh Corbett Taylor Young, John Zuill, M.A.

SOCIETY OF APOTHECARIES OF LONDON.—The following candidates, having passed the qualifying examination in Medicine, Surgery, and Midwifery, have received certificates entitling them to practise in the same, and have been admitted as Licentiates of the Society on Oct. 10th:—

Collett, Henry George Outram, King's College.

On the 16th:—

Bristow, George Hamilton, St. Thomas's Hospital.
Cornilliac, Joseph, King's College Hospital.
Dawber, John Henry (B.A. Oxon.), Middlesex Hospital.
Lory, Arthur George Bateman, London Hospital.
McInerny, John, College of Physicians and Surg., New York.
Neville, Evan James, King's College Hospital.
Pritchard, Edward Josiah, Westminster Hospital.
Wilson, Helen Mary, Royal Free Hospital.

On the 17th:—

West, William Frederick, St. Bartholomew's Hospital.

COLLEGE OF PHYSICIANS IN IRELAND.—At the October Examinations the following gentlemen obtained the Licences in Medicine and Midwifery of the College:—

Medicine.—Philip Cormack, Sydney Fielder, Frederick Wm. Smith Stone.

Midwifery.—Philip Cormack, Frederick William Smith Stone.

The undernamed was admitted a Member:—

Edward Young, F.R.C.S.I.

CONJOINT SCHEME OF THE COLLEGES OF PHYSICIANS AND SURGEONS IN IRELAND.—The following gentlemen have passed the First Professional Examination:—

E. A. Chartres, W. Coneys, J. G. Crozier, J. Flemming, J. E. Fox, R. P. Goode, J. V. Griffin, H. Hunt, R. D. Jephson, D. T. Kelly E. Kennedy, M. Kiely, E. J. King, P. J. Long, J. F. Maguire, J. P. Marnell, P. Merrin, C. E. Murphy, J. P. McCormack, H. McFadden, H. Nash, H. F. Nolan, J. C. O'Malley, M. K. Quinlan, C. M. Richards, J. Robinson, J. F. Sheppard, J. Skelly.

UNIVERSITY OF DURHAM.—At a convocation held on the 22nd inst., the degree of M.D. was conferred on Barrington Syer White.

SANITATION IN BOKHARA.—The Ameer of Bokhara has, it is stated, in consequence of his recent visit to Chardjui, ordered that the sanitation of his capital shall be scientifically inquired into and improved.

ST. LUCIA is unprovided with a lunatic asylum, the expense of providing one being an insuperable difficulty. Madmen have now to be attended at their own homes and watched by their own families.

FOOTBALL ACCIDENT.—A man named Dybull, who was goalkeeper, whilst playing at football, under Association rules, at Scarborough on Saturday, was accidentally knocked down by a player of the opposing team and had his leg broken.

INSANITARY DWELLINGS.—At an extraordinary meeting of the Islington Vestry held on the 18th inst., several houses in Nelson-place and Aston-buildings, Holloway-road, were, in accordance with the report of the medical officer of health and the Vestry's surveyor, ordered to be demolished.

COLLEGE OF PHYSICIANS IN IRELAND.—At a meeting of the Fellows, held on St. Luke's Day (18th inst.), the following office-bearers were elected for the ensuing year:—President: L. Atthill. Vice-president: George F. Duffey. Censors: G. F. Duffey, Joseph Redmond, Andrew Horne, W. Beatty. Additional Examiners: J. H. Benson (Medicine), E. Cosgrave (Medical Jurisprudence and Hygiene). Midwifery: W. J. Smyly. Examiners for License in Midwifery: Andrew Horne, W. J. Smyly. Examiners under the Conjoint Scheme.—Chemistry and Physics: Isaac Ashe, Henry Bewley. Materia Medica and Pharmacy: E. Cosgrave, F. Quinlan. Physiology: J. M.

Digitized by Google

Purser. Medicine: G. F. Duffey, Arthur Foot, C. J. Nixon, W. Beatty. Hygiene and Forensic Medicine: John Molony, Joseph M. Redmond. Examiners for the Membership.—Clinical Medicine: George F. Duffey, J. H. Benson. Pathology: H. T. Bewley, John M. Purser. Practice of Medicine and Public Health: W. Beatty, E. McDowel Cosgrave. Examiners for Diploma in State Medicine.—Chemistry: W. G. Smith. Climatology, Meteorology, and the Geographical Distribution of Disease: J. William Moore. Vital Statistics: S. MacSwiney. Hygiene: C. Nixon. Medical Jurisprudence and Pathoiogical Anatomy in relation thereto: G. F. Duffey. Representative on the General Medical Council: L. Atthill. Treasurer: A. Smith. Registrar: John W. Moore. Elected to the Fellowship: Henry C. Tweedy.

MEXBOROUGH COTTAGE HOSPITAL.—The committee who are furthering this scheme met again on the 12th inst. The movement is rapidly approaching completion in every respect, and the old school-room is being transformed into the requirements of a hospital, under the superintendence of Mr. G. White, agent of Mr. Montagu, who has given the building and is meeting the cost of the alterations.

IRISH MEDICAL SCHOOLS' AND GRADUATES' ASSOCIATION.—The autumnal general meeting of the Association will be held at 11, Chandos-street, Cavendish-square, London, W., on Thursday, Nov. 7th, at 5 P.M. In addition to other business, an alteration of Rule VII. will be proposed by the Chairman of Council. On the same evening the Association will dine at the Holborn Restaurant, at 7 P.M., Dr. Fegan, President, in the chair.

CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST.—Sir Risdon Bennett, M.D., F.R.S., will deliver an introductory address on Monday, Oct. 28th, at the Victoria-park Hospital. Clinical lectures and demonstrations will take place at weekly intervals, commencing Thursday, Nov. 7th, and ending Thursday, Dec. 12th, the lecturers being Dr. Thorowgood, Dr. Heron, Dr. Vincent Harris, and Dr. Ormerod. Full particulars can be obtained by application to Dr. H. Sainsbury, Victoria-park Hospital, E.

BRIDGWATER INFIRMARY.—The report submitted to the annual meeting of the subscribers on the 17th inst., which was adopted, was satisfactory alike in the good work done during the year as well as the financial condition of the institution. In the past year 258 in-patients and 1746 out-patients had received treatment, the largest number recorded for many years. The statement of receipts and disbursements showed a balance in hand of £161 4*s.* 6*d.*, against £45 brought over at the commencement of the year.

MEDICO-PSYCHOLOGICAL ASSOCIATION.—The next quarterly meeting of the Medico-Psychological Association will be held at Bethlem Royal Hospital, on Wednesday, Nov. 6th, at 4 P.M. A paper will be read by Drs. Dodds, Strahan, and Greenlees, on "Assistant Medical Officers in Asylums; their Status in the Specialty." Dr. Baker will show and describe a new form of urinal and a fireguard with spring lock in use at the Retreat, York; also an inspection plate for asylum doors, and marble tiling for Turkish baths. Pathological specimens will also be exhibited.

BEQUESTS AND DONATIONS TO HOSPITALS.—By the will of the late Miss E. M. Jowitt, of Woodfield, Potternewton, the following bequests are made, free of legacy duty: To the Leeds General Infirmary, £500; Edinburgh Medical Missionary Society; £500 and the Zenana Bible and Medical Mission, £300.—Mr. Hamilton Hoare, of Fleet-street, London, has given a donation of £50 to the Royal Hospital for Diseases of the Chest, City-road; and a lady has sent a donation of 50 guineas to the same institution.—The late Mr. Stafford Henry Northcote, of 120, Belgrave-road, Pimlico, has bequeathed £100 to the Royal Free Hospital, Gray's-inn-road, London.—Miss E. Ansted, late of Brooklands, Landford, Wilts, has left by her will £100 each to the Salisbury Infirmary and the British Home for Incurables, Clapham-rise, and £20 to the City of London Lying-in Hospital.—Mrs. Blomfield Moore has given £500 as a thankoffering to the Samaritan Free Hospital for Women and Children, London.—The late Misses Eliza and Jessie Lochore of Minerva Lodge, Lenzie, have bequeathed, free of legacy duty, £300 each to the Glasgow Royal Infirmary and the Glasgow Western Infirmary; £200 to the Glasgow Royal Sick Children's Hospital; £100 each to the Eastpark Cottage Homes and the Lenzie Convalescent Home; £50 each to the Glasgow Eye Infirmary and the Glasgow Medical Mission.—An anonymous donation of £50 has been received by the Governors of the Devonshire Hospital at Buxton.—The Secretary of the Cardiff Infirmary has received £5 from the Cardiff United Bicycle Club.

PROPOSED NEW HOSPITAL AT STAFFORD.—An influential meeting has been held at the Guildhall, Stafford, under the presidency of the Earl of Harrowby, for the purpose of deciding upon the advisability of erecting a new hospital in place of the present one, which has been in existence for 120 years. A committee of investigation had recommended that a new building should be provided on a new site, whereby it was estimated that a considerable saving would be effected. It was believed that for a sum of £10,000 a model hospital could be built, providing accommodation for eighty persons. It was recommended that the sum of £5000 be raised by public subscription, the remaining £5000 being realised for the old building. A motion that the work for the erection of a new hospital be proceeded with was then carried, and a committee was appointed to that end.

UNIVERSITY COLLEGE, DUNDEE.—At the annual meeting of the governors of this College, the report of the Council, which was adopted, stated that £9000 had been promised for the endowment and equipment of a chair of Physiology, and that, although a further sum of £6000 was required to properly endow the chair, yet, looking to the importance of the medical school being equipped as speedily as possible, the Council had resolved to proceed with the appointment of a professor. The financial statement showed that the debt of the College had been increased from £5000 to £6500, and the Council appealed for donations to wipe off the balance outstanding against the College. The Rev. Colin Campbell said it was gratifying to find that while the number of students was increasing, the students were taking a continuous course. He thought sufficient reasons could be advanced to warrant them proceeding to teach the subject of physiology even with a partial endowment. Unless some provisions were made for the teaching of physiology at present, not only would the anatomy students be left in a state of suspended animation, but the Council would labour under the disadvantage of their students departing to Edinburgh, where they could complete the education they desired.

BERLIN VITAL STATISTICS.—In the week from Sept. 15th to Sept. 21st, 862 children were born alive in Berlin, 109 of whom were illegitimate; 31 were born dead, including 3 illegitimate. The number of deaths was 501. Six died of scarlet fever, 1 of enteric, 30 of diphtheria, 1 of quinsy, 7 of whooping-cough, 3 of puerperal fever, 5 of typhus, 1 of syphilis, 12 of old age, 12 of cerebral apoplexy, 23 of inflammation of the lungs, 82 of consumption, 29 of diarrhœa, 24 of cholera nostras, 12 of intestinal catarrh, and 1 of delirium tremens. The number of violent deaths was 19, 1 by burning or scalding, 3 by drowning, 4 by hanging, 1 by suffocation, 2 by running over, 4 by falls or blows, and 4 by shots. Eleven of these deaths were suicides. Of the deceased 174 were under one year, 58 from one to five years, 26 from five to fifteen, 11 from fifteen to twenty, 28 from twenty to thirty, 39 from thirty to forty, 97 from forty to sixty, 60 from sixty to eighty, and 8 over eighty; 137 died in hospitals, including 14 who had come from other places to be treated here. The death-rate for the said week was 17·4 per 1000 of the total population of 1,500,103. The death-rate in the same week in Aix-la-Chapelle was 27·8 per 1000; in Altona, 16·3; in Breslau, 27·4; in Chemnitz, 23·6; in Dantzic, 20·9; in Dresden, 18·3; in Düsseldorf, 18·9; in Elberfeld, 16·2; in Frankfort-on-the-Main, 20·2; in Hamburg and suburbs, 20·3; in Hanover, 21·2; in Cologne, 20·3; in Königsberg, 26·2; in Krefeld, 12·7; in Leipsic, 19·3; in Magdeburg, 16·3; in Munich, 28·3; in Nürnberg, 24; in Stettin, 25·7; in Strasburg, 22·6; and in Stuttgart, 17. The death-rate in London in the same week was 15·2; in Paris, 21·5; in Liverpool, 18·9; in Dublin, 28·5; and in Amsterdam, 16·5.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.*

CADDY, ARNOLD, L.R.C.P. Lond., M.R.C.S., has been appointed House Surgeon to the Leeds General Infirmary.

DANIEL, W. P., L.S.A., has been appointed Assistant House Surgeon to the Female Lock Hospital and Asylum, Harrow-road, W., vice H. J. L. Bullen, resigned.

DAVIES, D. S., L.R.C.P. Lond., M.R.C.S., has been reappointed Medical Officer, Bristol Port.

ESLER, R., M.D., M.Ch., L.M., Q.U.I., has been appointed Divisional Surgeon to the Metropolitan Police P Division, vice P. G. Philps, M.R.C.S., resigned.

EWENS, G. FRANCIS W., M.D., has been appointed Honorary Physician to the St. Pancras and Great Northern Dispensary, Highgate.

FLEMING, R. M., L.R.C.P., L.R.C.S. Edin., has been appointed Medical Officer of the Holbrook District, Samford Union.

HEAVEN, J. C., L.R.C.P. Lond., M.R.C.S., has been reappointed Assistant Medical Officer, Bristol Port.

MEIGHAN, T. S., M.D., M.B., C.M. Glas., has been appointed Professor of Ophthalmic Surgery, Anderson's College Medical School, Glasgow.

MILLER, J. T. ROGER, L.S.A. Lond., has been appointed District Medical Officer and Public Vaccinator for the Leavening District of the Malton Union, vice Wm. Deeley, M.D., L.K.Q.C.P.I., resigned.

MOORE, A. J., M.R.C.S., L.S.A., has been reappointed Medical Officer of the Parish of St. Lawrence, Reading Union.

OGLE, C. J., M.R.C.S., L.S.A., Anæsthetist to the Gordon Hospital for Fistula, &c., has been appointed Surgeon, vice the late Mr. Benton.

ORD, WM. THEOPHILUS, M.R.C.S., L.R.C.P. Lond., has been appointed Medical Officer and Public Vaccinator to the Halesowen District of the Stourbridge Union, vice T. McLauchlan, M.B. Edin., resigned.

PARSONS, F. J. C., L.R.C.P. Lond., M.R.C.S., has been reappointed Medical Officer for the Port Sanitary Authority, Bridgwater.

POLLOCK, R., M.B., C.M., F.F.P.S. Glas., has been appointed Medical Officer of the Burgh of Pollokshields, Glasgow.

SNADDEN, JAMES, M.B., C.M. Edin., has been reappointed Medical Officer No. 4 District, Wortley Union.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement.

CENTRAL LONDON SICK ASYLUM DISTRICT, Cleveland-street Asylum, Cleveland-street, W.—Assistant Medical Officer and Dispenser. Salary £100 per annum, with board and residence.

CHARING-CROSS HOSPITAL, London.—Surgical Registrar, for one year, at a salary of £40, but the holder is eligible for re-election.

CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, Victoria-park, E.—House Physician for six months. Also Resident Medical Officer. Salary £100 per annum, with board &c.

COUNTY BOROUGH OF HUDDERSFIELD.—Medical Officer of Health for the Borough and Urban Sanitary District of Huddersfield. Salary £400 per annum, with actual disbursements in addition.

GLOUCESTER FRIENDLY SOCIETIES' MEDICAL ASSOCIATION.—Locum Tenens, out-door.

GORDON HOSPITAL FOR FISTULA &C., 278, Vauxhall-bridge-road, S.W.—Assistant Surgeon.

LEICESTER INFIRMARY AND FEVER HOUSE.—Assistant House Surgeon. Salary £80 per annum, with board, apartments, and washing.

LIVERPOOL DISPENSARY, 34, Moorfields, Liverpool.—Two Assistant Surgeons. Salary £80 per annum each, together with apartments, board, and attendance.

LIVERPOOL ROYAL INFIRMARY.—Honorary Surgeon.

MIDDLESEX HOSPITAL, W.—Second Chloroformist to the Hospital.

NORTH RIDING INFIRMARY, Middlesborough-on-Tees.—House Surgeon.

NORTH-WEST LONDON HOSPITAL, Kentish-town-road.—Junior Resident Medical Officer for six months.

PARISH OF EDAY, Orkney, to Inspector of Poor.—Resident Medical Officer. Salary £70 a year and practice.

PARISH OF THE UNITED PARISHES OF WHITTLESEY.—District Medical Officer and Public Vaccinator. The Medical District comprises the northern portion of the parish; the Vaccination District comprises the outlying portion of the parish. The salary as District Medical Officer will be £70 per annum, with the usual extra medical fees for midwifery and surgical cases. The fees for vaccination and revaccination will respectively be 3*s.* and 2*s.* per case.

PARKER DIXON, Esq., Solicitor, 13, Gray's-inn-square, London.—Assistant Medical Officer, in a large Metropolitan Lunatic Asylum. Salary to begin at £100 a year, with board, lodging, washing, &c.

ROYAL LONDON OPHTHALMIC HOSPITAL, Moorfields, London, E.C.—Clinical and Junior Assistants. The former for one year, but the officer is re-eligible, and the Junior Assistants for six months, also re-eligible.

SALISBURY INFIRMARY.—A Dispenser. Salary £105 per annum; out of doors.

SALOP INFIRMARY, Shrewsbury.—House Surgeon. Salary £100 per annum, with board and residence.

SOUTH-WESTERN FEVER HOSPITAL, Landor-road, Stockwell, S.W.—Two Clinical Assistants. The remuneration is limited to residence and rations.

VICTORIA HOSPITAL FOR SICK CHILDREN, Queen's-road, Chelsea, S.W. Ophthalmic Surgeon.

WEST BROMWICH DISTRICT HOSPITAL.—House Surgeon. Salary £80 per annum, with board, residence, and washing. Also Assistant to the House Surgeon. No salary, but board, residence, and washing.

WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL, Wolverhampton.—House Surgeon. Salary £100 a year, with board, lodging, and washing.

Births, Marriages, and Deaths.

BIRTHS.

ALEXANDER.—On Oct. 21st, at the London County Asylum, Hanwell, W., the wife of Dr. Robert Reid Alexander, of a daughter.

COLLIER.—On Oct. 12th, at High-street, Oxford, the wife of W. Collier, M.D., of a son.

DONKIN.—On Oct. 21st, at South-hill-park, Hampstead, the wife of Charles Donkin, L.R.C.P. Edin., of a daughter.

FRANCIS.—On Sept. 3rd, at Sooke, near Victoria, Vancouver Island, the wife of Harry A. Francis, L.R.C.P., M.R.C.S., of a daughter.

HUNT.—On Oct. 20th, at Crouched Friars, Colchester, the wife of Edgar A. Hunt, surgeon, of a son, prematurely, stillborn.

KIDD.—On Oct. 18th, at Brook-street, Grosvenor-square, the wife of Percy Kidd, M.D., F.R.C.P., of a son.

MAC COMBIE.—On Oct. 19th, at the Hospital, Hatfield-street, New-cross, the wife of Dr. John Mac Combie, of a daughter.

PERN.—On Oct. 16th, at Botley, Hants, the wife of Alfred Pern, F.R.C.S., of a son.

WARREN.—On Oct. 19th, at New Brompton, Kent, the wife of E. C. Warren, surgeon, of a daughter.

MARRIAGES.

CAVENAGH—WHITEHEAD.—On Oct. 9th, at Haslingden, John Paul Cavenagh, of Hull, L.K.Q.C.P.I., L.R.C.S.I., to Annabella, second daughter of Thomas Hoyle Whitehead, Esq., J.P., Holly Mount, Rawtenstall, Lancashire.

COLLINS—POTTS.—On Oct. 16th, at the Parish Church, Broseley, George Duppa Collins, M.R.C.S., L.S.A., to Selina, youngest daughter of the late George Potts, Esq., solicitor, Broseley.

HAYES—BARRY.—On Oct. 16th, at Ballyadam, Patrick Aloysius Hayes, Surgeon-Major Medical Staff, to Edith, second daughter of the late Wm. H. Barry, Esq., J.P., Ballyadam, Carrigtohill.

MARSHALL—DONALD.—On Sept. 25th, at St. Mary's, Bathwick, Bath, by the Rev. Colmer Godwin, curate of Christ Church, Torquay, Arthur Lumsden Marshall, M.A., M.B. Cantab., fourth son of Major-General W. B. Marshall, late Royal (Bengal) Artillery, to Margaret Minnie Helen, youngest daughter of the late John Donald, Deputy Inspector-General of Military Hospitals, and late of the 24th Regiment.

ROBERTSON—COPELAND.—On Oct. 22nd, at the Parish Church of Rainton, by the Venerable Archdeacon of Durham, assisted by the Rev. Hugh McNeil Minton-Lenhouse, M.A., Rector of Tillingstone Lovell, brother-in-law of the bride, Cecil Robertson, M.B., C.M., Smeeston, Somerset, son of W. P. Robertson, Esq., of Aberdeen, to Mabel Beatrice, third daughter of the Rev. G. Dale Copeland, B.D., Rector of Rainton.

DEATHS.

DAVIDSON.—On Oct. 17th, at Culross Park, Culross, Perthshire, Robert Halkerston Davidson, M.D., late Deputy Inspector-General of Hospitals of Her Majesty's Indian Army, Bombay.

GROSVENOR.—On Oct. 7th, at Ladbroke-grove, Notting-hill, George Fox Grosvenor, M.D., eldest son of the late William Grosvenor, Esq., aged 61.

JOHNSTONE—On Oct. 19th, at his residence, High View, Ramsgate, Henry James W. Johnstone, F.R.C.S. and J.P., eldest son of the late James Johnstone, M.D., Physician to King William the Fourth.

LAWTON.—On Oct. 19th, at 136, York-road, Lambeth, Richard Lawton, aged 87.

LEON.—On Oct. 19th, at Redcliffe-gardens, S.W., Hananel de Leon, M.D., formerly of Kingston, Jamaica, aged 92.

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editors."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed to the Sub-Editor.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "to the Publisher."*

We cannot undertake to return MSS. not used.

A NEW TITLE FOR THE NEW ORDER OF APOTHECARIES.

WE have received several communications on this subject, the new apothecaries evidently desiring strongly a title expressive of their larger qualifications. Mr. A. R. Willson, of the Radcliffe Infirmary, Oxford, argues that as the new qualification is called a "Diploma in Medicine, Surgery, and Midwifery," and certifies competency to practise in all these branches, the holder is not sufficiently described by the title L.S.A. He argues from the above facts that their legal title is Dipl. in Med., Chir., & Obstet., L.S.A., and this is the description he advises every new licentiate to adopt. Mr. R. R. Sleman, of 7, St. Benet's-place, E.C., forwards us a form of petition to the General Medical Council to give the new licentiates "such title or titles as will convey to everyone the increased scientific status which such further study must necessarily confer." We should advise the new licentiates to take counsel with themselves and with the authorities of the Society before petitioning the Medical Council. The Medical Council has no power, we apprehend, to confer new titles. It is for the Society or its members to procure an alteration of the law that will allow the Council to register new licentiates under a juster title. The Council might be asked again to favour such a reasonable amendment of the law; but the simpler the language in which such a request is couched the better.

Mr. James Wigg.—1. The membership of the Royal College of Surgeons, England, did not confer a qualification in medicine before the Conjoint Scheme.—2. The licence of the College of Physicians, London, did confer a qualification in surgery before the Conjoint Scheme.

E. F. F.—1. The appointments are in the hands of the chairman of the Prisons Department, Sir Edmund Du Cane.—2. The Crown Agents for the Colonies, Downing-street, S.W.

Jeyes' Sanitary Compounds Co.—The matter shall receive attention.

TOUTING AMONGST FAITH-HEALERS.

To the Editors of THE LANCET.

SIRS,—The following exact copy of a letter recently addressed to a lady patient of mine may amuse and interest your readers. I may add that it is in an illiterate hand, as the mixture of French and English and the absence of punctuation will show.

I am, Sirs, yours faithfully,

Middle-lane, Hornsey, N., Oct. 23rd, 1889. A. GOLDNEY CHITTY.

"Near at Hand, 23 Sept., 1889.

"MA CHERE MADAME,—If you have not full confidence in your present medico and feel disposed to try the efficacy of prayer send for

"Yours obediently

"MARTIN MICHEL."

QUACKERY IN BRAZIL.

A BRAZILIAN medical journal complains bitterly of the sometimes vexatious restrictions with which the law surrounds the legitimate practitioner, while, on the other hand, the quack goes quite free. Every medical man, on coming to settle in a district, has to present his diplomas to the authorities for inspection, and also to pay fees for a licence to practise; the quack, of course, does nothing of the kind. Again, if a medical man sees an infectious case in the ordinary course of his duty, he is obliged by law to incur some expense and inconvenience for the protection of the public. The quack, on the other hand, if he sees an infectious case, an illegal act in itself, is not in the least troubled by sanitary regulations—indeed, he may sign death certificates and perform many other acts which for him are distinctly illegal without any of the authorities taking the smallest notice.

Anilins.—Lunge's "Coal-tar and Ammonia," 1887, gives a good account of the preparation of crude products from coal-tar. As to such complex compounds as antipyrine, no popular description is possible. Attfield's Chemistry, 13th edition, 1889, describes briefly the most important.

X. Y. Z. might put the questions to his medical adviser.

THE NEW ENTRIES.

To the Editors of THE LANCET.

SIRS,—We shall doubtless before long have the official returns of new entries at the medical schools. Should the numbers show a gain it will be an occasion for congratulation amongst professors and all interested in the numerical prosperity of their schools. A different feeling, however, will be awakened in the breasts of the rank and file of the profession should the returns show an increase upon last year's, for they have everything to lose and nothing to gain by a growth in numbers on the register, sharpening, as it inevitably will, the present almost intolerable keenness of competition.

On the general question of overcrowding in the profession THE LANCET has more than once spoken fearlessly and forcibly, but I am desirous of calling attention to one cause of the evil in question which has not, I think, been hitherto touched upon. I allude to the touting for students by the medical schools through the advertisement columns of the general press. Surely the facilities for advertising are ample enough in the medical journals to aid those who have already made up their minds to enter the profession in selecting the school best suited to them.

If there is any doubt in the minds of our hospital authorities as to the existence of overcrowding in the profession, or of the deplorable results arising therefrom, let them walk through our suburban as well as our thickly populated, more central neighbourhoods, and witness the profusion of so-called dispensaries, with shop fronts emblazoned with gold letters on "a sea" of chocolate, setting forth the wonderful skill of the proprietor and the cheapness of his wares. If this sight does not raise a blush for "the cloth," it is quite certain our fathers would have felt ashamed had such a spectacle greeted their eyes.

I am, Sirs, your obedient servant,

Oct. 16th, 1889. C. W. C.

ALBUMINURIA.

To the Editors of THE LANCET.

SIRS,—The circumstance of Dr. Saundby quoting from a different lecture of Dr. Graves from the one referred to by me renders his remarks on my note of the 8th inst. comparatively irrelevant. For the rest, if ever there was a man less likely to be hampered by the trammels of doctrine—the pitfall of medical men—Dr. Graves was that man. His illustrious pupil, Stokes, said of him: "He was a true physician"—not too common a commodity now-a-days. He revolutionised the practice of medicine in the treatment of fever. He *fed it*, relegating the Sangrado treatment which had hitherto obtained to well-merited oblivion, thus forming the germ, as I think, of conservative medicine. His views on capillary circulation, on the doctrines of inflammation (confirmed by microscopical investigations), on circulation of blood within the cranium (confirmed by Dr. Burrowes' experiments), on the pathology of paralysis (so remarkably in accord with the cerebro-spinal theory), on the pathology of tubercle, on the nature of the acid in the human stomach, &c. &c., make up a roll of medical achievements destined to fill a bright page of medical history, and equalling, I humbly apprehend, anything that has been done by "Kidney Bright."—Yours faithfully,

Oct. 21st, 1889. A PUPIL OF THE LATE DR. GRAVES.

CIRCUMCISION.

To the Editors of THE LANCET.

SIRS,—In Dr. Smith's "Concise Dictionary of the Bible," under the heading "Circumcision," is the following passage:—"The process of restoring a circumcised person to his natural condition by a surgical operation was sometimes undergone. Some of the Jews in the time of Antiochus Epiphanes, wishing to assimilate themselves to the heathen around them, built a gymnasium at Jerusalem, and that they might not be known to be Jews when they appeared naked in the games made themselves uncircumcised (1 Macc., 1, 15)." Will any one of your readers kindly inform me what this surgical operation was?

I am, Sirs, yours truly,

Huntingdon, Oct. 22nd, 1889. LANCELOT NEWTON.

Digitized by Google

THE CLIMATOLOGICAL AND HYDROLOGICAL CONGRESS IN PARIS.

WE are informed that our correspondent was in error in implying that the United States was not officially represented at the Congress, Dr. A. Lawrence Rotch having, it appears, been delegated by the U.S. Commissioner-General at the Exposition for that purpose.

Dr. R. Rentoul (Liverpool).—Our space will not permit of the insertion this week of our correspondent's letter, which, however, will appear in our next.

GEYSER BATHS.

To the Editors of THE LANCET.

SIRS,—As the publicity now given to the dangers of these baths is due entirely to the evidence which I gave at the inquest on Reginald Chapple, I beg you will allow me to add a few words in further explanation.

The statement made by the coroner, Mr. Wyatt, was that, though this "accident" had occurred, there was a kind of "geyser" which did not require a funnel, and which was perfectly safe to use. I then opposed that opinion on the ground that in a bath-room of small cubic space, like the one in question, no apparatus of such a kind could be safe, owing to the rapid consumption of the oxygen of the apartment, and I do not care what kind of burner it may be provided with, whether Bunsen's or otherwise. I would also venture respectfully to differ from the writer of the annotation in your last issue, in which he says of the funnel (which should in all cases be provided): "The latter should not be carried out of doors, as the wind may blow back the fumes into the bath-room, but should be conveyed into an adjoining corridor or large room." This advice is surely inconsiderate, as in any case it must fill the house with noxious fumes, even when the draught is sufficient to clear the bath-room; and I can readily imagine a house of such a construction that even leaving the bath-room door open whilst the geyser is in action might have a similar result. Would it not be in every way better to recommend clearing the atmosphere of the bath-room from the possible regurgitation of fumes by opening both door and window for half a minute after the geyser burners are extinguished? In the meantime the funnel may be relied on to create its own draught at all times when the gas is fully turned on.

As deaths from the deoxygenation of the air of small rooms are at least twice as numerous in England as those from hydrophobia, I trust you may be able to find room for this warning.

I am, Sirs, your obedient servant,

Upper Norwood, S.E., Oct. 9th, 1889. EDWARD HAUGHTON, M.D.

"TELEGRAM—IMMEDIATE—NO CHARGE FOR DELIVERY."

To the Editors of THE LANCET.

SIRS,—Everybody's name and address in the "Medical Directory" should be followed by his telegraphic address, thus: (T. A. Liston, Surgeon, Ainsdale); or (T. A. Abernethy, Physician, Elter Water.) Such telegraphic address need not be a registered telegraphic address (for which the Post-office requires a guinea a year), but simply an abbreviated address which each man knows by experience is sufficient to ensure the prompt and correct delivery of his telegrams. When we telegraph to our London friends we spend nearly sixpence in name and address before we come to the words of the communication. All *un*registered telegraphic addresses in London, Dublin, &c., should conclude with the name of the *delivering office*, as the Post-office calls it, and this can be ascertained by inquiry at the nearest post-office to your residence. The editors of the Medical Directory must have information supplied before Nov. 1st, or it will be too late for the Directory for 1890. I am, Sirs, yours truly,

October, 1889. CRAVEN, Surgeon, Kendal.

COMBINARE.

IN our notice last week of the material under this name (which, by the way, was wrongly spelled "combinaire") we inadvertently omitted the address, No. 12, Gray's-inn-road, after the name of the inventor, Mr. Stoward.

DENTITION IN UTERO.

To the Editors of THE LANCET.

SIRS,—As a sequel to the letter of Mr. James Henry Clark, in your issue of Oct. 12th, I beg to say that I was called in to-day to remove two lower incisors from the mouth of an infant aged twenty-two days. They were there at birth, and had become so prominent and loose that the mother was anxious to have them removed. I enclose them with this letter, and may add that it is by no means the first case in my experience. I am, Sirs, yours truly,

Biggleswade, Oct. 14th, 1889. J. B. EMMERSON.

Mr. R. C. Nicholls.—We would refer our correspondent to an article in THE LANCET of Sept. 14th, p. 540. For the other side of this question see our issue of last week, p. 809.

"TREPHINING THE SACRO-ILIAC JOINT IN SACRO-ILIAC DISEASE."

To the Editors of THE LANCET.

SIRS,—In the report of the above case in your last issue, p. 787, are two errors. May I ask you to kindly correct the same, as materially affecting the diagnosis and treatment of the case? The patient could not sit on the *right* tuber ischii, not "left." For "two-inch limb" read two-inch *limit*. I am, Sirs, yours faithfully,

New Cavendish-street, W., Oct. 23rd, 1889. MAYO COLLIER.

ADVANCE IN MICROSCOPIC BACTERIOLOGY.

BY means of an improved microscope made by Seibert of Wetzlar the internal structure of the anthrax bacillus can be made out. This consists of a series of pearl-like corpuscles, which can be plainly seen to undergo division. The magnifying power of the microscope is said to be 2250 diameters.

Mr. W. J. Fraser.—The person extolled in the paragraph of the *London Weekly Telegraph* sent us is not in the Medical Register.

H. E.—Tribune Médicale of Oct. 3rd.

THE EXAMINATION IN SURGERY AT THE ROYAL COLLEGE OF SURGEONS AND THE EXAMINATION HALL.

To the Editors of THE LANCET.

SIRS,—If the Court of Examiners of the above institutions could arrange to take the *viva voce* part of their examination on the same day as the written (Friday), or even on Saturday, the next day, instead of having to wait till Monday and Tuesday respectively of the following week, it would be a great saving of expense and inconvenience to provincial students, who could take their departure immediately on the conclusion of the examination, the same or next day, instead of waiting about the town for nearly a week with no chance of enjoyment, and with no definite result, except that of emptying their pockets and evaporating their greater or less stock of assurance; for who can possess a serene and contented mind under the prospect of facing such an uncertain ordeal as an examination in medical knowledge amounts to, where the gravity and anxiety of the situation are enhanced by its being successfully or otherwise the means of deciding the result of four, six, or even eight years of toil and labour?

I have the honour to remain, Sirs, your most obedient servant,

October, 1889. A CANDIDATE.

PRACTICE IN BUENOS AYRES.

To the Editors of THE LANCET.

SIRS,—Can any of your readers kindly inform me how I should set to work in order to obtain a practice in Buenos Ayres or the immediate vicinity of the town? Any information as to opening, &c., will greatly oblige, Yours faithfully,

Oct. 21st, 1889. L.R.C.P. & S.

THE LATE ALBERT SMITH'S WORKS.

To the Editors of THE LANCET.

SIRS,—Can any of the readers of your valuable journal inform me if it is possible to get a copy of one of Albert Smith's old works—"The London Medical Student"?—I am, Sirs, yours faithfully,

ALFRED CORRIE,

Hull, Oct. 21st, 1889. Staff Surgeon, H.M.S. *Rupert*.

COMMUNICATIONS not noticed in our present number will receive attention in our next.

COMMUNICATIONS, LETTERS, &c., have been received from—Mr. Mayo Collier, London; Mr. Christopher Heath, London; Dr. Bate; Mr. T. Bird; Dr. Horrocks, London; Mr. A. G. Chitty, Hornsey; Dr. Auld, Glasgow; Mr. L. Newton, Huntingdon; Mr. Sweeten; Dr. Hopkirk, London; Mr. A. E. Nevins, London; Dr. Norbury, Plymouth; Dr. J. Young, Stewarton; Mr. A. MacDougall, Richmond; Mr. C. J. Marsh; Dr. T. K. Clarke, Huddersfield; Dr. McKeown, Belfast; Mr. H. H. Taylor, London; Dr. Edmunds, London; Mr. Sunter; Dr. Collier, Oxford; Mr. Greenleaves; Mr. Fraser; Dr. F. H. Alderson, Hammersmith; Mr. Edge, Manchester; Dr. Wallace, Colchester; Dr. Lees, London; Dr. Skerritt, Bristol; Dr. Shuttleworth, Lancaster; Mr. A. Corrie, Hull; Mr. J. E. Blomfield, Sevenoaks; Dr. Stephenson, Hanwell; Dr. H. P. Hawkins, London; Dr. Ormsby, Dublin; Mr. Thorpe, Walthamstow; Dr. Maguire, London; Mr. M. Palmer; Mr. J. E. Thompson, Vienna; Mr. R. Harrison, London; Mr. Friend; Mr. J. P. Bush, Clifton; Mr. Christy, London; Messrs. Willows, Francis, and Butler, London; Dr. Montague, Nottingham; Messrs. Kingsford and Co., London; Dr. Walker, Redcar; Mr. Blake, Dublin; Mr. Musgrave Craven, Kendal; Mr. Yearsley, London; Mr. Sleman; Dr. Fancourt Barnes, London; Dr. O'Neill, Belfast; Dr. R. Medical Diary for the ensuing Week.

Monday, October 28.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations, daily at 10 A.M.
ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1.30 P.M., and each day at the same hour.
CHELSEA HOSPITAL FOR WOMEN.—Operations, 2.30 P.M.; Thursday, 2.30.
HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M., and on Thursday at the same hour.
METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.
CENTRAL LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M., and each day in the week at the same hour.
UNIVERSITY COLLEGE HOSPITAL.—Ear and Throat Department, 9 A.M.; Thursday, 9 A.M.
CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, VICTORIA-PARK, E.—4.30 P.M. Introductory Address by Sir Risdon Bennett, M.D., F.R.S.
MEDICAL SOCIETY OF LONDON.—8.30 P.M. Dr. Ord: Some interesting points in connexion with Glycosuria.—Mr. Maxmaduke Shield: Cerebral Abscess due to Ear Disease, evacuated by the Trephine.

Tuesday, October 29.

GUY'S HOSPITAL.—Operations, 1.30 P.M., and on Friday at the same hour. Ophthalmic Operations on Monday at 1.30 and Thursday at 2 P.M.
ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 4 P.M.; Friday, 2 P.M.
WESTMINSTER HOSPITAL.—Operations, 2 P.M.
ST. MARY'S HOSPITAL.—Operations, 1.30 P.M. Consultations, Monday, 2.30 P.M. Skin Department, Monday and Thursday, 9.30 A.M. Throat Department, Tuesdays and Fridays, 1.30 P.M. Electro-therapeutics, same days, 2 P.M.

Wednesday, October 30.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 10 A.M.
MIDDLESEX HOSPITAL.—Operations, 1 P.M.
ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour. Ophthalmic Operations, Tuesday and Thursday, 1.30 P.M. Surgical Consultations, Thursday, 1.30 P.M.
ST. THOMAS'S HOSPITAL.—Operations 1.30 P.M.; Saturday, same hour.
LONDON HOSPITAL.—Operations, 2 P.M. Thursday & Saturday, same hour.
SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN.—Operations, 2.30 P.M.
GREAT NORTHERN CENTRAL HOSPITAL.—Operations, 2 P.M.
UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.; Skin Department, 1.45 P.M.; Saturday, 9.15 A.M.
ROYAL FREE HOSPITAL.—Operations, 2 P.M., and on Saturday.
KING'S COLLEGE HOSPITAL.—Operations, 3 to 4 P.M.; Friday, 2 P.M.; Saturday, 1 P.M.
CHILDREN'S HOSPITAL, GREAT ORMOND-STREET.—Operations, 9.30 A.M.; Surgical Visits on Wednesday and Saturday at 9.15 A.M.

Thursday, October 31.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M. Surgical Consultations, Wednesday, 1.30 P.M. Ophthalmic Operations, Friday, 1.30 P.M.
CHARING-CROSS HOSPITAL.—Operations, 2 P.M.
UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.; Ear and Throat Department, 9 A.M.

Friday, November 1.

ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.
WEST LONDON MEDICO-CHIRURGICAL SOCIETY (Board-room, West London Hospital).—8 P.M. Pathological Specimens:—Mr. R. F. Benham: An Umbilical Cord Knotted Ante Partum.—Mr. Keetley: Specimen showing Three Incomplete (Richter's) Strangulated Hernia in the same subject (a man aged seventy-six).—Mr. R. Lake: A Hypertrophied Tonsil. Cases:—Dr. Abraham: An unusual case of Psoriasis.—Mr. Keetley: A Girl aged fifteen with a Congenital Lateral Curvature of the Spine and a Double or Bifid Row of Spinous Processes in the Mid-dorsal Region. Microscopical Specimens:—A series illustrative of Phthisical Conditions of the Lungs, lent by Mr. Arthur Townsend of Birmingham.—Dr. Abraham: Sections of Psoriasis. Papers:—Dr. Thudichum: A New Mode of Operating on Nasopharyngeal Tumours (so-called relapsing).—Dr. Reginald Dudfield: The Sanitary Acts of last Session, especially the Infectious Diseases (Notification) Act, 1889.

Saturday, November 2.

MIDDLESEX HOSPITAL.—Operations, 2 P.M.
UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.; and Skin Department, 9.15 A.M.

ABSTRACT OF

An Address

ON

SCHOOL HYGIENE,

AND ON

MEDICAL GUIDANCE IN THE SELECTION OF SCHOOLS FOR CERTAIN CHILDREN.

Delivered at the Sanitary Institute of Great Britain on July 16th, 1889,

BY CLEMENT DUKES, M.D.LOND., &C.,
PHYSICIAN TO RUGBY SCHOOL AND SENIOR PHYSICIAN TO RUGBY HOSPITAL.

IN his opening remarks the lecturer explained that to attain the end they had in view—the production of a capable and vigorous race—the conditions must be gathered from the nature of the case and from experience. The gardener would tell them that no plant would be healthy and reach its normal development which had been checked in growth. "Keep it growing" was his constant lesson; then, and only then, would it fulfil its destiny in nature. Yet this was precisely the course which they were constantly neglecting in dealing with the human plant, which was sometimes placed under favourable circumstances, but at other times, and more frequently, under conditions the most adverse. For convenience, and to avoid repetition, he would only refer to the education of boys, but he wished it to be understood throughout that every suggestion was equally applicable to girls, who were so grossly neglected in the matter of education, and especially in the appliances which were necessary for physical education. In order that the highest physical growth might be attained during school life, it was necessary that the constitution of every child should receive a careful estimate of its capacity previous to the commencement of that period of life—a period of the first importance, embracing the years of most active growth, from eight to nineteen years of age. In speaking of the choice of a school for a child, his remarks obviously only applied to parents who were in a position to exercise a choice. To advise the poor to select an appropriate school would be as wise as to recommend the choice of a particular brand of champagne. Hitherto the medical profession had had little or no voice in the selection of an appropriate school for the individual child, and parents had usually sent their children to this or that school, on the ground that they themselves had been educated there, or because a friend had a boy or girl at the same school; so that the payment of the school cheque, promptly or otherwise, had been alone accepted as the criterion of their duties to their children in the matter of education. Without desiring to interfere with this arrangement when the children were the healthy children of a healthy stock, he did protest with all the force of which he was capable in the case of: (1) Children who were delicate or sickly; (2) children who had had an ailment which would recur under unfavourable circumstances; and (3) children who were healthy at the present time, but who were the offspring of parents who, as they advanced in years, developed ailments or diseases which had an hereditary tendency, and which medical men knew were apt to be transmitted sooner or later to the children, though medical men at the same time also knew that the possibly latent disease might be eradicated, or mitigated, were the child surrounded by favourable conditions during the period of school life. Not to heed such tendencies to disease, now that medical science was sufficiently advanced to lend an effective helping hand, was a parental neglect which might hamper the child through life and occasion untold misery, not only to the boy himself, but also to his future wife and children, by entailing his premature death, or often even worse, that moroseness of character which ill-health so frequently engendered. The lecturer then proceeded to give the two following cases as illustrative of his remarks:—

"1. Some time since I attended a little boy who was exceedingly ill with a chest illness. The course pursued by the illness caused me considerable anxiety, until I ascertained that he was born in India, and had had an illness from malaria during his residence there. I at once saw that his present illness was masked by this prior malaria fever, and on the administration of quinine and arsenic he speedily recovered. I heard recently that he was being educated to compete for a scholarship at a school situated close to the bed of a river, whose meadows at certain times of the year are frequently under water. I represented to the guardian of the boy that such a situation was most undesirable. My protest was heeded, and I have little doubt that, if the child be educated in the place where I advised, his ague will gradually, and I hope completely, wear itself out during his growing years, and that he will attain a healthy manhood. Had his parent persisted in sending him where he had proposed, the intermittent fever would have found a fitting soil for its continual recurrence, and would have clung to him throughout his life, or produced internal disease, such as spleen, with all its miseries and inconveniences. A clever boy would thus have been handicapped through life simply from ignorance of the importance of the subject. 2. A few weeks ago a friend of mine, an oculist, asked my opinion about a patient, a pale-faced, precocious, strumous boy, who was an only child, overgrown, listless, and stooping. He was suffering at the time from recurring attacks of iritis, depending upon synechiæ, the sequelæ of a former attack of rheumatic iritis, and had been living for many years near a brackish swamp. My opinion was sought because the parents had placed the boy at the most unsuitable school for such a constitution that could have been selected—a school unsuitable for any but the soundest and most robust. I advised that if the parents persisted in returning such a type of boy to that school, and he were mentally, morally, and physically ruined, the blame would rest upon the parents alone. For, as he could not thrive under such circumstances, sustained application to work would be impossible, and he would become a 'loafer,' with all its attendant evils. The sequel shows that the process I predicted was already taking place. I inquired of my friend, for the purpose of quoting this case to-day, what was the result of our advice, and he writes a characteristic reply: 'You might as well try to walk arm-in-arm with a grasshopper as to try to persuade that unfortunate boy's clerical father that there is any better school on earth for his son than the school at which he himself was a boy.' The result we expected came sharper than even I anticipated. 'He returned to school, and within a few weeks ran away from the school and came to London with another boy.' Now, had this boy been sent to a school where he would have improved in health and become vigorous, he would have worked well and played well, and would have become a credit to himself and his parents. I insist that this boy demands pity, the parents deserve blame; whereas the parents would seek your sympathy in their heartrending trouble, especially as he was an only child."

The lecturer next proceeded to refer to—1. Adolescents who had not suffered from any previous illness, but who had never thriven, and who were subject to continual *delicacy*, *anæmia*, and frequently repeated *catarrh*. 2. Adolescents who suffered from deficient or deteriorated health, arising from previous illness occurring during childhood. This class would include those who had suffered severely from a "*fever*," such as typhoid fever and scarlet fever; a long illness from an *inflammatory disease*, as pleurisy and joint disease; and *rickets*. Parents might say that their child was in its usual health, and had not ailed since the illness. But it was manifest to others that the child was pale and thin, not thriving, and had made no way since the illness in question. 3. Diseases which had already occurred during childhood and were liable to recur during adolescence. Under this heading he would class such diseases as *malaria*, *rheumatism*, asthma, neuralgia, albuminuria, and diarrhœa. 4. Hereditary disease in the parent which is liable to manifest itself in the offspring during childhood or to develop after childhood. Amongst these he would enumerate *gout*, *Bright's disease*, *nervous diseases*, and *tubercular disease*. The lecturer insisted that much could be done for those children by placing them in a healthy situation where they

Digitized by Google

might pass their school life. With care and judgment in the selection not only of a well-placed but a well-built school, properly ventilated throughout, with large sunny rooms by day and large open dormitories by night, so that they could not breathe pre-breathed air, these children would respond to the influence of a healthy situation during school life beyond all expectations, and would outgrow the delicacy of their youth.

On the subject of Asthma, the lecturer said:—

"In the case of *asthma*—a frequent ailment during adolescence—I can, I regret to say, offer very little advice as to choice of situation, since the disease is one which exhibits the most curious and remarkable vagaries. Some children are quite free from attacks at the seaside; others in a town; others in the country, either in low-lying districts or on high levels; some where there are pine trees; others where the air is keen and dry; while others again can only breathe easily where the air is warm, moist, and relaxing. In one of the worst cases I ever had under my care, where every remedy had failed to give relief in the place where he was being educated, I inquired in despair whether there was any place on earth where he could breathe comfortably. The boy smiled, and replied that he could breathe with perfect ease on the Underground Railway in London, and that when he was at home he sometimes took a return ticket from one end of the line to the other, solely for the purpose of enjoying the pleasure of breathing with comfort. But in a worse case than this I summoned the father, for I feared a fatal termination, from a very long distance. On his arrival I asked if he knew any place where his son could draw his breath with ease; and he said, 'Yes, at home.' But inasmuch as he lived a forty-eight hours' journey away, and that across the sea, the difficulty to be faced was that of transporting the boy alive. However, I urged the trial, as I feared death from exhaustion if he remained. While we were discussing the question deep snow was on the ground, but a thaw came at the time of starting, and when the travellers, with all the appurtenances for his terrible attacks, arrived in London a dense fog prevailed, which at once mitigated the severity of the attacks, and the boy went comfortably to bed, was able to lie down, which he had not been able to do for several weeks, and slept most of the night, instead of sleeping only in momentary snatches as heretofore, and eventually he reached home safely. Whatever might be the course advised for those who were the victims of this unfortunate illness, it could only be tentative. Again, children having an hereditary tendency to tubercular disease should pass their earliest school years at the seaside, and their public school life at a spot where the conditions were suitably adapted to their physical state; where their vigour would be such that tubercular bacilli would find no fit soil in their organism in which to develop. There were many schools admirably located for the education of such a type of constitution. But that horrible legend, 'Because I was at school there, and my father before me, and we have all been educated there for generations,' has such fatal hold upon parents that some specific thought for the child never for a moment emerged from this ancestral lunacy. One cannot but admire the feeling of pride, constancy, and gratitude which made a parent adhere to the school of his fathers; but, on the other hand, human welfare might thereby be sacrificed to a mere tradition."

The lecturer pointed out the importance of class-rooms in schools being systematically ventilated and equably warmed by hot-water pipes rather than by fires; and, with regard to dormitories, he insisted that in bedrooms, where about nine consecutive hours were passed, each boy should have allotted to him at least 800 cubic feet of space and seventy-two square feet of floor space, with plenty of floor space between the side of each bed.

In conclusion, the lecturer said:—"I will epitomise the gist of this address in a few words. I have striven to point out that there are certain types of children, hitherto rarely considered, to their great detriment, who require special care during their school years to enable them to contend against adverse circumstances and to reach a healthy manhood. The kind of care required varies considerably in individual cases; but in the main it may be asserted that it is fatal to the attainment of a vigorous manhood if such children grow up in a cold, damp atmosphere; on a wet soil or subsoil; in small, dark class-rooms; and in the confined atmosphere of a cubicle. In place of these conditions, their constitutions imperatively demand that they should spend these years of development in a dry atmosphere, and in a locality sufficiently elevated to be free from the effects of a damp soil and subsoil. They also require that the aspect of all their rooms should be sunny; that the class-rooms should be large, light, and above ground; and the dormitories large and open, and unoccupied by day. Under these simple, but essential, conditions, delicate children will enjoy the best chance—which is obviously their due—of developing in health and vigour, and becoming not merely hardy in themselves, but the transmitters also of a constantly improving race. To help adult age and old age out of their illnesses and diseases is a noble work; but to prevent disease arising in the young, and thus enable them to grow up in health and vigour, is the noblest work of all."

ON THE TREATMENT OF PNEUMONIA BY THE ICE-BAG.[1]

BY D. B. LEES, M.D. CANTAB., F.R.C.P.,
FORMERLY SCHOLAR OF TRINITY COLLEGE, CAMBRIDGE; PHYSICIAN TO AND LECTURER ON MEDICINE AT, ST. MARY'S HOSPITAL; SENIOR ASSISTANT PHYSICIAN TO THE HOSPITAL FOR SICK CHILDREN.

FOUR YEARS ago I published in the *British Medical Journal* (July 11th, 1885) an account of "Two Cases of Broncho-pneumonia Treated with Bleeding and Ice." I was much impressed with the good results that in each of these cases followed, and appeared to be due to, the persistent application of an ice-bag to the chest wall over the inflamed lung. Since that time I have taken such opportunities as have occurred to me of testing the use of the ice-bag in cases of pneumonia, and my impression of its value and of its great superiority to poultices and other warm applications has been so greatly strengthened, that two years ago I mentioned the matter to some of my friends who have large opportunities of clinical observation in hospitals and elsewhere, and asked them to give the ice-bag a fair trial. Several physicians have been good enough to comply with my request. If their opinion of this method of treatment prove to be as favourable as my own, practitioners of medicine generally may be encouraged to employ it, and by a sort of informal collective investigation it will then stand or fall. It can only be by the careful observation of a large number of individual cases that a satisfactory demonstration of its value can be obtained; for pneumonia is pre-eminently a disease in which it is easy to arrive at false conclusions with regard to the effect of treatment. The remarkable "crisis" which usually marks the close of a pneumonia is a trap for the unwary therapeutist, and any remedy the employment of which has preceded this striking event is only too likely to be credited with having produced it. And the fact that the crisis may occur at any period of the disease, from the third day to the tenth, makes it specially difficult to be sure that an apparent cutting short of the pyrexial process may not be simply the natural course of its development. To this deceptiveness of clinical experience is no doubt largely due the remarkable variation in medical opinion about the proper treatment of pneumonia. And the difficulty of correct inference is greatly increased by the fact that a condition so alarming in its appearance when at its height nevertheless usually recovers completely when the patients are children or young adults, except under special circumstances. Too often has the natural course of the disease appeared to give proof of the efficacy of some particular line of treatment, and venesection, leeches, tartar emetic, aconite, veratrine, digitalis, quinine, and alcohol have each in turn had their enthusiastic advocates. In advocating the employment of the ice-bag in pneumonia I am desirous of bearing these fallacies in mind.

The use of cold applications to the chest in pneumonia was advocated twenty years ago by Niemeyer. He used, however, not the ice-bag, but cold compresses, which are certainly far inferior to the ice-bag, through their tendency to become warm, and the necessity they entail of frequent disturbance of the patient. Niemeyer says: "I have made extensive employment of cold in the treatment of pneumonia, and, relying upon a large number of very favourable results, can

[1] A paper read before the Harveian Society, Oct. 17th, 1889.

Digitized by Google

recommend this procedure. In all cases I cover the chest of the patient, and the affected side in particular, with cloths which have been dipped in cold water and well wrung out. The compresses must be repeated every five minutes. Unpleasant as this procedure is in almost all cases, yet even after a few hours the patients assure me that they feel a material relief. The pain, the dyspnœa, and often the frequency of the pulse, are reduced. Sometimes the temperature goes down an entire degree. My patients often retain this surprising condition of improvement throughout the entire duration of the attack, so that their outward symptoms would hardly lead one to imagine the grave internal disorder. The relatives of the patient, too, who do not fail to perceive the improvement, now readily assist in the treatment to which at first they were opposed. In a few cases, and only in a few, the use of cold affords no relief, and the troublesome manipulation for its application increases the distress of the sufferers so much that they refuse to keep it up. In such cases I have not insisted upon the further application of cold. In the hospital at Prague every pneumonia is treated with cold compresses, and, according to the statements of Smoler, it is exceptional for a patient not to feel material relief from this treatment. As, however, I have never succeeded in cutting short a pneumonia by means of cold applications, I should only ascribe a palliative influence to their use, had not the duration of the disease in many instances been decidedly shortened and the convalescence hastened by means of their energetic and methodical employment. In fact, in but few cases have we seen the disease delay its departure until the seventh day. Many have improved on the fifth, and a very large number as early as the third day; nay, I have repeatedly found it impossible to keep patients with recent pneumonia in hospital for a longer period than a week." This quotation from Niemeyer (vol. i., p. 185) bears striking testimony to the benefits obtained from the use of cold compresses frequently renewed, while acknowledging the drawbacks inseparable from their use.

My observation of the effects of the ice-bag has satisfied me that we may by it obtain still more striking benefit without these drawbacks. The ice-bag retains its cold until all the ice in it is melted; hence it produces a much more powerful local impression, and a fall of temperature considerably larger than the "entire degree" of which Niemeyer speaks, while the much less frequent disturbance of the patient and the freedom from wetting of the surface remove entirely the objections to which he refers. I have found that the presence of the ice-bag is usually pleasant to the patient, and I have never met with any decided objection to its use, even in children. Only occasionally where delirium has been present has the ice-bag been thrown off.

I will now briefly relate my experience of this method of treatment, and will classify the cases according to the apparent effect.

A. CASES IN WHICH IMMEDIATE AND FINAL ARREST OF THE PYREXIAL PROCESS FOLLOWED THE APPLICATION OF THE ICE-BAG.

Case 1.—William W——, aged twenty-five, was admitted into St. Mary's Hospital on the evening of Nov. 15th, 1887, with a temperature of 104°, which fell next morning to normal, but had again risen when I saw him in the afternoon to 104·8°. There was limited pleuro-pneumonia at the right base, skin burning, herpes round the mouth. Pulse 120; respiration 36. This was apparently the fifth day of the disease, he having shivered on Nov. 12th, and again on the 13th. The affected side was tightly strapped, and an ice-bag applied over the strapping. The temperature fell immediately, and next morning was normal, when the ice-bag was removed; the pulse was 90, and respiration 24. After this the temperature was subnormal. Clearly the crisis had occurred, and whether or not the ice-bag had hastened it must be a matter of opinion. Possibly it may have been simply a coincidence.

Case 2.—John P——, aged twenty-six, admitted on June 18th, 1887, with a temperature of 104°, and a limited area of dulness at the left posterior base, pulse 120, respiration 24, on the fifth day of his illness, shivering having occurred on June 14th. The temperature continued about 104°, until I saw him on the seventh day, when an ice-bag was applied over the inflamed lung. During the following night the temperature fell until it reached 99°, when the ice-bag was removed. A rise of one degree followed, but next morning (ninth day) the temperature was normal, and so continued. Here, again, the apparent result from the ice-bag may have been a mere coincidence.

Case 3.—Maurice W——, aged sixteen, seen at Uppingham school, with Mr. T. Bell, in February, 1886, on the fourth day of his illness. The temperature was 104°, and there was moderate consolidation at the right base, with viscid, rusty sputum. No ice was obtainable, but snow was lying on the ground. Sponge-bags filled with snow were placed over the inflamed lung. The temperature fell at once (fifth day), and did not again rise. Once more we must remark that the apparent effect may possibly have been nothing more than a coincidence. This, however, was certainly not so in Case 4, the subject of which was my own youngest child, aged three years. He had suffered from catarrh for two or three days, when he rapidly became acutely ill; the temperature ran up to 104°, the breathing was very rapid, and his lips began to look a little dusky. Just the faintest impairment of resonance was to be detected at the base of one lung. He passed a most restless night, and in the morning was no better. Some ice was sent for, and an ice-bag applied to the suspected area. Within twenty minutes of its application a distinct change for the better was observed. The breathing became much quieter. The temperature fell at once. In a few hours he was quite out of danger, and in a day or two was quite well. I am convinced that an attack of broncho-pneumonic was cut short.

Case 5.—In December, 1886, I was asked by a friend, a well-known physician, to see his little boy, aged four years. After a week's catarrh, the boy's temperature had suddenly risen to 104·5°; pulse 140; respiration 50, occasionally interrupted by a short cough. The cheeks were a little dusky. I found a shade of loss of resonance at the left base below the angle of the scapula. At this spot, and also at the corresponding spot on the other side of the chest, inspiration was a little harsh, and attended by a little râle, and expiration was too plain. It was clear that broncho-pneumonia was just commencing. An ice-bag was applied to the back of the chest, and immediate recovery followed, the improvement being remarkably rapid. In this case, as in that of my own child, I have no doubt that the pneumonic process was strangled at its birth.

B. CASES IN WHICH IMMEDIATE ARREST OF THE PYREXIAL PROCESS FOLLOWED THE APPLICATION OF THE ICE-BAG, AND A RELAPSE FOLLOWED ITS REMOVAL.

Case 6.—Jenny McN——, a girl of about four years old, in the Highgate convalescent branch of the Children's Hospital, was found one day to have a temperature of 104°. I saw her next day, and found that there were dulness and bronchial breathing over part of the lower lobe of the right lung, with a hot burning skin and temperature still 104°. An ice-bag was at once applied over the affected lung, and within a few hours the temperature fell to 98°. The ice was then removed. The temperature immediately rose again, but did not pass 101°. It continued at this lower level for about thirty-six hours, and then suddenly fell to 96·5° and remained subnormal. The day after this fall examination showed that both dulness and bronchial breathing had completely vanished. In this case the immediate fall of six degrees which followed the application of the ice was clearly not the crisis, for on removal of the ice pyrexia recurred (though to a much less extent) and continued for thirty-six hours before the final drop.

Case 7. Caroline S——, aged thirty-eight, was admitted into St. Mary's Hospital on Jan 7th, 1889, and I saw her next day, the fourth of her illness, a rigor having occurred during the evening of Jan. 4th. The temperature was 103°, pulse 128, respiration 44. Dulness and tubular breathing were present over the left axillary base. She was slightly jaundiced. An ice-bag was applied at 3 P.M. At midnight the temperature had fallen to 99·6°, and the bag was removed. Immediately the temperature again rose, at 10 A.M. of the next (the fifth) day it stood at 101·5°, and at 6 P.M. at 104°, actually a degree higher than before the application of the ice. It then began to descend in a leisurely fashion, reaching 100·5° by the evening of the sixth day, 99·2° on the seventh evening, 99° on the eighth, and 98·4° on the ninth. Thus there was no marked crisis at all, and the recurrence of the pyrexia after the removal of the ice clearly proved that the process was not yet over, and that the sudden drop of 3·5° in nine hours which accompanied the use of the ice was certainly due to it.

C. CASES IN WHICH IMMEDIATE ARREST OF THE PYREXIA FOLLOWED THE USE OF THE ICE-BAG, A RELAPSE FOLLOWED ITS REMOVAL, AND A SECOND FALL OCCURRED WHEN THE ICE WAS REAPPLIED.

Case 8.—Thomas C——, aged nine, was admitted into St. Mary's Hospital on July 14th, 1887, with pleuro-pneumonia of the left base. He had been caught in the rain on July 9th, felt ill on the 10th, but went to school on the 11th and 12th; pain in his side commenced on the 13th. On admission his temperature was 103°, pulse 128, respiration 48. An ice-bag was immediately applied, and the temperature fell moderately quickly, reaching 99·4° thirty-six hours later, when the ice was removed. At once an upward movement of temperature began, and in eight hours it had risen to 104°. Again the ice was applied, and again the temperature descended, but more rapidly than before, reaching 98·4° in sixteen hours more, after which it did not again rise above 100°. This terminal crisis occurred on the fifth day, reckoning from the initial pain. The more gradual fall of 3·5° which followed the first application of the ice was clearly due to it, as was shown by the relapse which followed its removal.

Case 9.—Henry B——, aged twenty-six, was admitted into St. Mary's Hospital on June 24th, 1887, on the second day of a pneumonia of the left base, several rigors having occurred on the morning of the previous day. I saw him on the third day; his temperature was then 103°, pulse 116, respiration 32; physical signs limited, but characteristic. An ice-bag was applied, and the temperature fell promptly to 97·6° on the morning of the fourth day. The ice was removed, and the temperature rose at once; when it reached 100° the ice-bag was replaced. The rise, however, continued as far as 102°, from which it fell again to normal on the fifth day. Here the beneficial action of the ice seems to be manifest, firstly, in the rapid fall of temperature on the third day; and, secondly, in the fact that the subsequent rise did not attain a higher level than 102°.

Case 10.—Mary T——, an infant aged six months and a half, seen in consultation with Dr. Langston of Westminster. This is one of the two cases published four years ago. It proved a complicated one, through the occurrence of otitis and commencing meningitis, which was on two occasions relieved by puncture of the tympanic membranes performed by Mr. Field. In the early part of her illness she nearly succumbed to broncho-pneumonia. Leeches gave immediate relief to her cyanotic condition, but the temperature still stood at 105°, and the physical signs of consolidation over the root of the right lung were marked. After an ice-bag was applied the temperature fell in twenty-four hours to 101·4°. The bag was then removed, and the temperature rose to 103°, but fell again till it reached 100·4°. A sudden rise to 105·6° followed, and was accounted for by the discovery of a fresh patch of dulness over the root of the other (the left) lung. The ice-bag was applied to this new focus of inflammation, and at once a very rapid fall of temperature followed. In nine hours after the application of the ice it had fallen no less than 7°—from 105·6° to 98·8°,—though the ice was removed when it had fallen to 102°, and I noted that the new dull area was distinctly smaller than it had been in the morning. Three days later there was another rise to 106°, again accounted for by the discovery of a small fresh area of dulness behind the edge of the left scapula, the two areas already mentioned as previously consolidated being now both completely resonant. Again ice was applied to the new site of inflammation, and again there was a rapid fall to 102·4°, when the ice was removed. A transitory rise to 104° followed, and then a quick descent to 99°. The lung trouble was now practically at an end, but the temperature rose again owing to the otitis &c., which now began to manifest itself. In the long run the child recovered perfectly. A complete account of the case was published in the *Practitioner* for Aug., 1886.

D. CASES IN WHICH RAPID FALL OF TEMPERATURE FOLLOWED THE APPLICATION OF ICE, BUT RELAPSES (APPARENTLY DUE TO IMPLICATION OF FRESH PORTIONS OF LUNG) OCCURRED WHILE THE ICE WAS BEING CONTINUOUSLY APPLIED.

Case 11.—Emily B——, aged fifteen, was admitted into St. Mary's Hospital on Jan. 24th, 1885, with severe broncho-pneumonia. This is the other case published in the *British Medical Journal*. She had been ill ten days before admission, and was found to have general bronchitis, with dulness over the whole front of the left lung, with a temperature of 104·2°. Poultices were applied to the chest. Next day she was worse, the temperature had risen to 105°, the physical signs were more marked, the pulse was 136, the respiration 44, and there was very considerable lividity of the lips and cheeks. Venesection to ten ounces was performed, and gave great immediate relief. The temperature fell one degree, but rose again as much in the evening, and next day was higher than ever, reaching 105·6°, the pulse then being 144, and the respiration 48. An ice-bag was now applied over the left front. Immediately the temperature fell precipitately, and next morning it was only 98°. In the afternoon, however, it rose again to 105·8°. On examination I found that the resonance over the left front, where the ice-bag had been applied, was remarkably improved, but fresh pneumonic crepitation and bronchial breathing had appeared in the axillary region. The ice-bag was shifted to this new focus, and again the temperature fell precipitately to 98°. It rose once more to 103°, and fell again to 98°. On the fourth day after the use of the ice was commenced there was a final rise to 104·2°, which proved to be due to implication of the apex of the opposite lung, there being now impaired resonance and harsh inspiration below the right clavicle. A second ice-bag was applied to this spot, and, to my surprise, twenty-four hours later I found the right apex perfectly normal. The temperature had fallen to 96·7°, and after this convalescence was uninterrupted. In this case the beneficial influence of the ice was quite indubitable, and the contrast shown by the temperature chart before and after its employment is most remarkable. The severity of the case was sufficiently demonstrated by the cyanosis, which necessitated recourse to venesection.

Case 12.—John S——, aged thirteen, was admitted into St. Mary's Hospital on Aug. 10th, 1888, on the fourth day of a pneumonia of the left base. His temperature was 105·8°. The house physician gave him five grains of quinine, and next morning his temperature was only 100·6°, but before 2 P.M. it rose again to 104·2°, when an ice-bag was applied over the inflamed lung. The rise continued until 6 P.M., when 105·4° was reached, but a rapid fall followed, and at 10 A.M. of the next (the sixth) day the temperature was only 100·2°. In spite, however, of the continued application of the ice, there was a rise in the afternoon to 103°, but this proved very temporary, and next morning (the seventh) 99° was again reached, and the ice-bag was removed. After this convalescence followed.

E. CASES IN WHICH NO IMMEDIATE ARREST OF THE PNEUMONIA FOLLOWED THE APPLICATION OF ICE, BUT OBVIOUS RELIEF TO SYMPTOMS RESULTED.

Case 13.—Minnie C——, aged twenty, admitted into St. Mary's Hospital on April 10th, 1888, on the seventh day of a pneumonia of the right base. Her temperature was 104·4°, and an ice-bag was at once applied. There was a fall of three degrees in the next few hours, but next morning the temperature was again 104°, in spite of the continued application of the ice, and it remained between 103° and 104° for three days. On the tenth day there came a sudden fall to 98°, and the ice was removed. On the eleventh day, however, it rose again to 102°, and the same happened on the twelfth day. Examination showed that the cause of this was the appearance of a small area of fresh inflammation at the base of the opposite lung. A second ice-bag was placed over this spot, and after this the temperature did not exceed 101°, and in three days more she was quite convalescent, the physical signs having disappeared. Here the ice-bag did not shorten the duration of the disease (unless, indeed, it may be credited with arresting an incipient attack on the previously healthy side), and it produced only temporary reduction of temperature, but the patient expressed herself as considerably relieved by it.

Case 14.—John L——, aged twenty-five, admitted into St. Mary's Hospital on July 9th, 1889, on the fourth day of a pneumonia affecting the apex of the right lung. I saw him on the fifth day and found his temperature 103·6°, pulse 120, and respiration 48, with viscid rusty sputum. He had been delirious during the night, and was still semi-maniacal and very surly, resisting examination, talking wildly, and accusing us of attempting to poison him. The physical signs of pneumonia at the right apex were distinct. An ice-bag was applied at 2 P.M., and in spite of his curious mental condition he did not object to it. A fall of temperature of two degrees and a half followed on the

Digitized by Google

morning of the sixth day; but in a few hours 103·6° was again reached. It was noted, however, that his mental state was markedly improved. On the seventh day the temperature was still 103°, but the delirium had vanished, and the physical signs at the right apex were less distinct. On the eight day still further improvement was manifest, and the temperature stood at 102° in the morning and fell rapidly to 99° in the evening, when the ice was removed. After this the temperature was subnormal, and the patient convalescent. In this case improvement in the physical signs distinctly preceded the crisis.

Case 15.—Mary A——, aged twenty, admitted into St. Mary's Hospital on May 11th, 1889, on the fourth day of a pneumonia commencing at the right apex. She had a most unfavourable family history. She stated that her father suffered from asthma, that her mother had died of "galloping consumption," that she had lost ten brothers and sisters, and that of the three who survived two suffered from consumption. She had herself spat blood at times during the last two years. She also had suffered from "fits" for four years, and the onset of her pneumonia was marked by a fit instead of a rigor. I saw her first on the fifth day of her illness, and found evidence of pneumonia at the right apex, with temperature 104°, pulse 128, and respiration 48. An ice-bag was applied over the affected apex at noon. At 6 o'clock the next morning the temperature had fallen four degrees, but in the course of the day it rose again to 102°. The pulse remained at 130, but the number of respirations had risen from 48 to 74, and some cyanosis had appeared. The upper part of the right lung both in front and behind was now dull, as far down as the angle of the scapula. On May 14th, the seventh day of her illness, the temperature was still only 102·5°, though the pulse was nearly 130, and the number of respirations had risen to 100. The right lung seemed now to be involved in its entire extent. Both cheeks were markedly cyanosed, and the sputum, which was scanty, very viscid, and a little aerated, was of exceedingly dark colour, almost black, the "prune-juice" expectoration of admittedly evil omen. A much larger ice-bag was now obtained, capable of surrounding the whole right chest, and this was applied at 5 P.M. Four ounces of brandy daily were ordered for her, and an ether and ammonia mixture every four hours. On the next day, the eighth, the temperature ranged about a degree lower (101·5°), the pulse remaining at 120, and the respiration still from 88 to 100. But it was observed that the sputum was distinctly less dark, and at the same time less viscid and more abundant. On the ninth day the temperature, pulse, and respiration remained about the same, but an extraordinary improvement had occurred in the physical signs. There was now very fair resonance over both back and front of the right lung down to the angle of the scapula, with large moist râles in front, and smaller râles with more natural breathing behind. Below the angle of the scapula there was dulness, with fine moist râles, both inspiratory and expiratory. There was still further improvement in the appearance of the sputum. On the tenth morning I found that though the temperature had been even a little higher (103°) and was still 101°, and the pulse and respiration were respectively 120 and 86, the improvement in the physical signs was still more marked. My note was: "Very fair resonance behind, even to the base; some impairment in the axillary region from the posterior to the anterior axillary line. Over the front, resonance good as far as the nipple. Over the whole lung bubbling sounds can be heard, moderately loud, and of double rhythm. Cheeks bright-coloured." Between 6 o'clock and 10 that evening the temperature suddenly fell from 101° to 97°; the crisis had arrived, and the ice-belt was removed. After this convalescence was complete. It must be allowed, I think, that in this case the ice was of the greatest service. It is hardly too much to say that it saved the patient's life. The condition on the seventh day, when the large ice-belt was applied, was most alarming. The entire right lung was consolidated, and the dyspnœa, the cyanosis, and the "prune-juice" expectoration indicated the gravity of the prognosis. Seventeen hours after its application a distinct improvement was observed in the sputum and in the hue of the cheeks. Next day a very extensive change for the better had occurred in the physical signs, and this improvement advanced rapidly. It had attained a most remarkable degree before the crisis occurred. It is surely uncommon in pneumonia for manifest improvement in physical signs to commence thirty-six hours before the crisis, and in this case it seemed certainly due to the local influence of the ice. The comparatively low range of the temperature throughout (after the ice was applied) should also be noticed.

Case 16.—Harry D——, seven years old, an inmate of the Highgate Branch of the Children's Hospital, with a retracted right chest due to former empyema, the right lung being entirely collapsed (as was found on post-mortem examination some months later), was taken ill on June 22nd, 1887. I saw him next day, and found his temperature 104°, pulse 160, respiration 56. Feeling sure, though I could not prove, that pneumonia of the left, the only working, lung was commencing, I had an ice-bag at once applied over it. The temperature fell four degrees before the next morning, but gradually rose again, not attaining the same height, however, for forty-eight hours. On the third day of his illness I detected a small area of dulness over the root of the left lung, and at this spot bronchial breathing. He complained of pain at the epigastrium, and I noticed that his lips and cheeks were already livid. This was not surprising, for his other lung was useless. The prognosis was evidently most grave, and might even have been looked upon as hopeless. Next day, the fourth, the dulness was more extensive, being now four fingers' breadth in diameter, and albuminuria was present, but the complexion was not more blue than yesterday, and the boy seemed a little stronger. The icebag had been persistently applied. Pulse 160, respiration 60. On the fifth day the dulness was decidedly less, measuring now only two fingers' breadth, and the temperature was lower, ranging at about 102°; pulse 152, respiration 58. Epigastric pain continued. The sixth day resembled the fifth. On the seventh day the temperature fell to normal, and the ice-bag was removed. Pleuritic friction could now be heard over the dull area and below it. The pleurisy kept his temperature a little raised for a few days, but it gradually subsided without effusion of fluid, and the boy returned to his condition before the pneumonia. By-and-by he was able to go home, but three months later he came back to Great Ormond-street, and died there from cardiac failure. Post-mortem examination showed that the right lung was completely collapsed, the right side of the heart greatly dilated, and the tricuspid valve incompetent, the left auricle and ventricle and mitral valve being normal. The left lung was very voluminous; it was healthy except for some very old cretaceous and calcified tubercle at its apex; there were comparatively recent pleuritic adhesions over the left lower lobe. In this case it is hardly possible to doubt that the icebag saved the boy's life, in a condition otherwise hopeless.

F. Cases in which no very Obvious Benefit resulted from the Use of the Ice-bag.

Case 17.—James R——, aged five, was admitted into St. Mary's Hospital on July 8th, 1887, on the third day of his illness. Next day his temperature was 104°, pulse 150, respiration 50. No signs of pneumonia, however, could be discovered until the sixth day, when the upper lobe of his right lung became consolidated. An ice-bag was applied and kept on until the crisis, which occurred on the eighth day. It was not clear that in this case any distinct benefit followed from its use.

Case 18.—Edward S——, aged about forty, was admitted into St. Mary's Hospital on June 28th, 1887, on the second day of his illness. He was found to have a limited pleuro-pneumonia at the right base, and also an area of dry pleurisy at his left base. It was noticed that the heart's action was very feeble. Temperature 104°, pulse 120, respiration 32. An ice-bag was applied to the right base, but at the same time whisky was ordered, and its amount was increased from four ounces on the third day to six ounces on the fourth day and to nine ounces on the fifth. It was difficult to say whether the ice-bag did good, though the range of temperature was a little reduced, but it certainly did no harm, in spite of the great cardiac weakness and the consequent necessity for free stimulation. On the evening of the fifth day came the crisis; the ice-bag was discontinued and the whisky was gradually reduced. Satisfactory convalescence followed.

The above is a complete list of the cases treated by the ice-bag, of which I have notes, though in two or three other cases seen in consultation I have recommended its use, and improvement has followed and apparently been caused by it. Reviewing the eighteen cases narrated, I

Digitized by Google

may point out, in the first place, that none of them died. Many of the cases, indeed, were comparatively slight, and most of them occurred in children or young adults, in whom the prognosis of lobar pneumonia is usually good, however alarming the symptoms may appear to be. At least two, however (Cases 15 and 16, both of lobar pneumonia), would, I think, have certainly died but for the ice-bag, and two more (Cases 10 and 11, both of broncho-pneumonia) would almost certainly have done so.

In the great majority of cases remarkable improvement followed the application of the ice. The reduction of temperature which usually occurred at once was often very striking. Instead of the "entire degree" spoken of by Niemeyer as resulting from the use of cold compresses, it frequently amounted to three or four degrees, sometimes even more; on one occasion even to seven degrees. If a subsequent rise occurred it was usually to a decidedly lower level when the ice had been permanently applied, and though when the ice had been removed the subsequent rise often passed the original height, it was again rapidly reduced by a second application. These results were especially observed in children, perhaps partly because their temperature is more easily affected than is that of adults, and partly because the icebag covered a larger proportion of their smaller chest wall. But the improvement was not confined to a mere reduction of temperature. In many cases I noticed a striking arrest in the development of the physical signs, and also of the general symptoms of the disease; and it is particularly to be observed that in some instances this improvement began an entire day or more before the crisis, and was far advanced when that event occurred. This was very remarkable in each of the two gravest cases (Cases 15 and 16). Occasionally, in slight cases, the application of the ice was followed by immediate complete abolition of the disease; but this is obviously open to the fallacy that the crisis may have already arrived, and I therefore lay no stress on this. But, in the two cases of broncho-pneumonia seen in young children in their very earliest stage, it certainly seemed that the disease was promptly cut short. I have never seen any harm follow from the employment of the ice-bag in pneumonia. In one case, indeed, the notes of which have been unfortunately lost—that of a boy of seven years old, with a pneumonia of the right apex, accompanied by a pericardial rub,—so rapid a reduction of temperature followed the use of the ice that the child shivered and was cold, and the house physician felt it necessary to stimulate him. But when I saw him the next morning he was very lively. In a case of pyrexia, however, recently under my care, in which the diagnosis was doubtful until a typhoid rash appeared, and in which an ice-bag was applied to the left lung on the hypothesis that the cause might be a latent pneumonia (the patient being a boy of about six), distinct collapse was produced by the cold applications. The temperature fell to below normal, the boy complained of cold, became bluish, and shivered. The symptoms were easily removed by warmth and brandy. Similar effects may no doubt be produced in pneumonia by the incautious use of ice. They are the more likely to happen the younger the patient, and they are probably more easily produced in cases of broncho-pneumonia, especially in feeble and rickety children, than in cases of true lobar pneumonia. That they need not necessarily occur, however, is manifest from Case 10, which was one of broncho-pneumonia in an infant of only six months and a half. Their occurrence may, I think, almost always be prevented by a sufficiently careful observation of the temperature. I usually direct, at all events in the case of young children, that the temperature shall be taken every hour, and the ice-bag removed when the thermometer indicates 100°, and replaced if a rise to 102° follows. In some cases it is wise to apply warmth to the feet or even to the abdomen at the same time that the ice-bag is applied over the inflamed lung, and the internal administration of brandy may then also be of service. With these precautions it is often possible to use the ice-bag even in debilitated patients without harm. It will be well, however, to draw attention to another point. Dr. Lauder Brunton has suggested to me that the occurrence of collapse may sometimes be due to the direct action of the cold upon the heart, and I have seen him perform an experiment on the excised heart of the frog which illustrates this. A frog is pithed, and the heart rapidly cut out and isolated. It continues to beat regularly. If now it be chilled by the application of ice, the pulsation diminishes until it entirely stops. If the ice be removed and gentle warmth substituted, the pulsations recommence and soon regain their former rate and vigour. This alternation can be repeated two or three times. The experiment clearly shows the depressing influence of cold on the action of the heart, and it is no doubt wise to bear this in mind, and see to it that the ice-bag is not placed over the præcordial region. But I do not advocate the employment of this treatment in pneumonia in very feeble children, in the aged, or in adynamic conditions generally.

My conclusion is, that there is reason to believe that the ice-bag applied over a pneumonic lung has a directly curative influence, that it does not simply reduce the general temperature, but that it distinctly tends to repress the inflammatory process in the lung, with more or less success according to the severity of the case, and the height which the inflammation has already reached. This is true, whatever theory of the causation of the disease be adopted. Coccus or no coccus, the ice-bag benefits an ordinary pneumonia. Whether its action is beneficial in the epidemic and "pythogenic" forms of the malady I cannot say, having no experience of these. I will only add, as confirmatory evidence, that some months ago my colleague, Dr. Angel Money, published a note in one of the medical journals recommending the use of the ice-bag in the pneumonia of children, and that in THE LANCET of Aug. 10th of this year there is a statement that Dr. Fieandt, a Finnish medical man, "has treated no less than 106 cases of pneumonia with ice, and with the best results. Though ten of the cases were of double pneumonia, only three out of the whole number succumbed, notwithstanding that the epidemic was by no means a slight one." Thus the mortality was only 3 per cent. With this may be contrasted some figures given in the same journal on July 27th of this year, in which it is stated that "in the 1000 cases of acute lobar pneumonia treated at the Massachusetts General Hospital from 1822 to the present time, there was a mortality of 25 per cent.;" and the authors add that "treatment has not influenced the mortality rate nor the duration of the disease or of its convalescence." If this rate of mortality had prevailed among my eighteen cases I should have lost four of them, and four is precisely the number which, as I have already shown, were almost certainly saved by the ice-bag.

ABDOMINAL SECTION FOR INTESTINAL OBSTRUCTION FOLLOWING OVARIOTOMY.

BY JOHN ANDERSON, M.D., C.I.E.,
PHYSICIAN TO THE SEAMEN'S HOSPITAL, GREENWICH; AND
MONTAGU HANDFIELD-JONES, M.D.,
OBSTETRIC PHYSICIAN IN CHARGE OF OUT-PATIENTS AND LECTURER ON MIDWIFERY AND DISEASES OF WOMEN TO ST. MARY'S HOSPITAL.

THE risks and complications of ovariotomy are so well known and have been so ably and fully set forth that there remains but little to be added. There is, however, one complication which has been so little noted, and of which such very few instances have been published, that it seems pardonable to put on record the full details of the following case.

Miss X——, single, aged forty-three, came under the care of my friend Dr. John Anderson in the latter part of the year 1888. At that time she was suffering from the presence of an abdominal tumour, of which the following history was given. The growth had been noticed for the first time some two years previously. It had slowly increased in size since, but had not caused marked pain, nor had it interfered very seriously with general health. Menstruation had occurred monthly, lasted on each occasion about four or five days, was not accompanied by much pain, and, though becoming rather less free, was still fair in amount. Several surgeons had been consulted as to the nature of the tumour, but, as no vaginal examination had been allowed, their opportunity for an accurate diagnosis was necessarily curtailed. Some of these gentlemen had suggested the possibility of the growth being cancerous, and one had thought that the tumour was probably a fibromyoma of the uterus, and did not call for operation. The family history of the patient presented two points of in-

Digitized by Google

terest—(1) her mother was still living and suffered from the presence of a large abdominal tumour, concerning the nature of which Miss X—— could give no reliable information; (2) pulmonary phthisis had declared itself in a marked form in several near relatives. The patient herself was a lady possessed of high intellectual gifts, cultivated and refined, but whose physique was by no means proportioned to her quick, nervous energy; eye and cheek alike suggested that pulmonary phthisis would find in her a favourable victim. Beyond the occurrence of several bronchial attacks, one of which had necessitated a residence in the south of France, there was no past history of any disease. After making an examination of the tumour by the abdomen, Dr. Anderson came to the conclusion that the growth was very possibly a solid tumour of the ovary, and suggested that an obstetric physician should see the patient in consultation with him. For some time this was declined by the friends, but in the end of January, 1889, permission was granted, and on February 2nd Dr. Anderson met me in consultation. The following was the condition at this time: The whole lower abdomen was occupied by a solid tumour, which, resting apparently on the brim of the true pelvis, extended upwards to a distance of two inches and a half or more above the level of the umbilicus. The mass, which was slightly larger than the uterus at the seventh month, was apparently throughout of a stony hardness, its surface was regular, it could be pushed somewhat from side to side, and the abdominal wall moved over it in respiration. The flanks seemed to be occupied by a limited quantity of ascitic fluid, and a sharp and sudden pressure on either flank sent a thin wave of fluid across the growth.

Vaginal examination under the influence of chloroform showed that the uterus was small, acutely retroflexed, low in the pelvis, and quite separate from the abdominal tumour. On pressing upwards firmly, the lower extremity of the latter could be felt resting on the brim of the true pelvis. A diagnosis of solid ovarian tumour, probably of a malignant type, and accompanied by ascitic effusion, was given, and early operation recommended. Careful examination had already shown that the heart, lungs, and other large organs were healthy. The urine was tested and found to be normal. The tumour had grown considerably during the last few months, pain had increased, and flesh and strength were both being lost. Menstruation was still regular, but scanty, of poor colour, and somewhat painful.

The operation was performed, on February 16th, 1889, at 3 P.M., Mr. Braine giving ether and Dr. John Anderson assisting me. On opening the peritoneum, about two pints of dark-coloured ascitic fluid escaped. Some old parietal adhesions existed, but they were easily separated. The tumour was entirely solid excepting at its left upper angle, where a small cyst extended upwards towards the spleen. Owing to the firmness of the mass it was impossible to lessen its bulk materially, and the abdominal incision had to be extended upwards for three inches above the umbilicus. As soon as the tumour had been drawn out of the abdomen the upper part of the wound was sewn up to prevent escape of the intestines, and then, the pedicle having been compressed by two large forceps, the growth was cut away. The pedicle, which was short, thick, and three inches and a half wide, was formed entirely by the right broad ligament. The tumour was a fibro-sarcoma of the right ovary, and had the right Fallopian tube passing round in front of its pedicle. Having transfixed and tied the latter, it was dropped into the pelvis, the cleansing and irrigation of the peritoneal cavity effected, and the abdominal wound closed by ten sutures. The operation, which lasted one hour and twenty-four minutes, was followed by great shock, but from this the patient rallied very satisfactorily.

As regards the abdomen, nothing could have progressed more satisfactorily. There was no sign of any peritonitis. The bowels were well relieved by enema on the sixth day, and when the stitches were removed on the eighth day, the wound had completely healed by the first intention. During this first week, however, complications in connexion with the lungs commenced. On the very morning of the operation Miss X—— remarked that she felt one of her heavy chest colds coming on, and complained to a friend how unfortunate it was, inasmuch as she had been free for a long time from such attacks. Of this, however, nothing was said to Dr. Anderson or myself. On the evening of the third day the temperature rose to 101° F., and the pulse to 120. A short irritable cough commenced, and breathing became hurried and oppressed. Examination of the chest showed that broncho-pneumonia had established itself in the anterior and upper part of the right lung. Two days later the corresponding part of the opposite lung was attacked similarly, then about three days after this extension the left back was found dull in its lower half, and well-marked pneumonia of the lower half of the left lung was found to be present. During the whole of this time the temperature kept up between 100° and 101°, but the abdominal condition was normal and the bowels were open daily.

On March 4th, 1889, the patient was seen by Dr. Anderson, and the following report given:—Miss X—— is progressing very favourably; pulse about 90, soft, weak, regular; temperature has come down to normal; bowels open twice yesterday after a dose of the liquid extract of cascara. There is no complaint of pain, and the nights are good. Examination of the chest shows the presence of high-pitched breathing in both fronts, but the moist sounds have disappeared. The right back is clear, but the lower half of the left back is still somewhat dull; moist râles are heard over the dull area, but there is no tubular breathing. Cough is becoming less troublesome, and there is a fair amount of muco-purulent expectoration.—5th: My colleague received a letter this morning from the nurse, saying that sickness had occurred at 10 P.M. on the previous night, and had returned several times since; the morning temperature had fallen to 96·2°; the bowels had been open slightly. In the afternoon Dr. Anderson saw the patient, found no reason to attach much importance to the vomiting, and regarded the gastric disturbance as connected with the defervescence of the pneumonia.—6th: The bowels acted naturally and copiously this morning. Vomiting has recurred three or four times since yesterday afternoon.—7th: The past night has been very restless; vomiting has taken place at intervals, and on the last three or four occasions has been distinctly "stercoraceous." The bowels have not acted since yesterday morning; the pulse is 128, small, regular, weak. Temperature normal. The abdomen is slightly tumid, but otherwise seems perfectly normal. All food by the mouth was at once stopped; nutrient enemata were ordered to be given every four hours; ice to be sucked in small quantities occasionally. A sedative solution of five minims of opium and one drachm of water was given every four hours, by the mouth. At 9 30 P.M. things were in much the same condition; no vomiting had occurred since 2 30 P.M., but there had been slight retchings with eructations, which smelt fæcal, and nothing had passed by the bowel. Tongue moist and clean.—8th: At 11 A.M. it was reported that there had been no more stercoraceous vomiting, but some retchings and fæcal-smelling eructations. Temperature normal; pulse 108, weak. Urine, fair amount and normal. Tongue moist, but coated. Abdomen somewhat fuller, but soft, moving well with respiration, not tender at any point, resonant everywhere. General condition not so good; weakness increasing. It was decided, as no stercoraceous vomiting had taken place for some considerable time, to test whether the integrity of the intestinal passage had been restored by giving teaspoonful doses of peptonised milk and raw beef juice alternately every half hour. At 6 P.M. Dr. Anderson paid a second visit, and found that the stercoraceous vomiting had returned severely at 5.30 P.M. At a consultation later in the day it was decided that probably some portion of the small intestine had become constricted by a band of lymph, which was gradually contracting and compressing a portion of the gut, and that abdominal section should be again performed next morning.—9th: Present condition—Patient much emaciated; she has lost much flesh and strength during the past week. The eyes are sunken, and large dark rings surround them. There has been no action of the bowels since Wednesday. Tongue moist, but coated. The abdomen is distinctly tympanitic, resonant everywhere, soft and supple, not tender, and moves fairly with respiration. At 11.30 A.M. the patient was etherised by Mr. Braine, and, assisted by Dr. Anderson, I again opened the abdomen along the line of original incision, from the umbilicus to within an inch and a half from the upper border of the symphysis pubis. After opening the peritoneal cavity, a careful investigation revealed the fact that a knuckle of small intestine had become firmly fixed by adhesive peritonitis to the wall of the cavity just above the position of the cæcum. So broad and so firm was the union that it was necessary to dissect off the parietal peritoneum and set the gut free with the adherent portion of the latter attached to it. As far as could be judged, the knuckle of intestine

Digitized by Google

involved corresponded to the upper portion of the ileum; many coils of small intestine below the seat of obstruction were found lying collapsed and empty, but before the operation was concluded these had become distended again. Before closing the wound careful search was made for any further adhesions, with the result that two coils of small intestine were found lying close to the promontory of the sacrum, connected by soft fibrous bands of recent formation; these latter were tied and separated, and then the peritoneal cavity having been freely washed out with douches of boiled water at 100° F., the wound in the abdominal wall was closed by twelve silk sutures. The operation lasted an hour and a half, and at its close the patient was much exhausted; but after being in bed about half an hour and having two ounces of brandy by enema a good reaction was secured. Soon after returning to bed about a pint and a half of yellow feculent fluid was vomited; but at 5 P.M. there had been no more sickness, a good rally had taken place, the pulse was 120 and much improved in force and volume, and the patient's countenance had lost its death-like appearance. At 6 P.M. a slight attack of stercoraceous vomiting occurred, and at midnight a little sour-smelling fluid (not feculent) was brought up; but after this time, though there was a little retching, no more vomiting took place. The usual dietary after abdominal section was observed; the patient rapidly improved, flatus was passed by the rectum about six hours after the operation, and on the fourth day the bowels acted freely and copiously without any recourse to aperients. A week later the stitches were removed, and though the wound gaped a little superficially, all the deep parts were firmly and strongly united.

A month later the condition of the abdomen was perfect, the patient had gained flesh, and, with the exception of some slight mischief remaining in the left lung after the pneumonia, the recovery was in every respect perfect.

Remarks.—In the light afforded by the second operation there is little difficulty in reading the course of events and explaining the formation of intestinal obstruction in the foregoing case. During the extraction of the large solid ovarian tumour from the abdominal cavity several old peritonitic adhesions passing from the wall of the abdominal cavity to the tumour were separated. On the right side, at the spot where the coil of small intestine was found glued to the parietal peritoneum, the latter had been rendered raw and bare by the tearing away of an adhesion with a broad base during the process of extraction of the growth. At the time of operation some extra care had to be given to this spot to stop bleeding and to trim up the torn surface of the peritoneum. Doubtless during the process of repair the knuckle of small intestine became fixed to this spot by adhesive peritonitis, then, as the days of convalescence went on, the gut was gradually constricted and narrowed by the contracting lymph, till at length the kinking and paralysis of peristaltic function led to complete obstruction. The difficulty experienced at the second operation in detaching the adherent intestine from the abdominal parietes was a proof that the adhesion had been steadily consolidating since the first operation, and very suggestive in itself of great interference with the function of that part of the bowel. The collapsed condition of the intestine below the seat of adhesion, and the way in which the gut became distended again after the adherent portion had been set free, left no doubt as to the site and completeness of the obstruction. The possible causes of intestinal obstruction after ovariotomy are manifestly numerous: fixation by adhesive inflammation to the pedicle, to the abdominal wound, to the site of separated adhesions, twisting of intestine by manipulation during the operation, inclusion of a loop of intestine in the pedicle ligature, slipping of a coil of the gut into surgical traps such as are formed when the pedicle is treated by the extra-peritoneal method, or when the stump of the broad ligament is stitched to the back of the abdominal wound, will readily suggest themselves. It is not, however, so much with the causation of the obstruction as with the possibility of making an early and accurate diagnosis that the surgeon has to do. Where the site of the accident may be, and by what means the block has been formed, can seldom if ever be decided with useful accuracy until the abdomen is reopened. Hirsch,[1] in his article on "Intestinal Obstruction following Ovariotomy," points out that the diagnosis has to be made under two different conditions: in one class of cases the obstruction is formed at the time of operation, as when a loop of intestine is included by the surgeon in his pedicle ligature; in the other class the obstruction forms slowly, as in the case now under consideration, and the patient has practically recovered from the ovariotomy before any signs of obstruction manifest themselves. In the second group the diagnosis is generally easy, and the decision of reopening the abdomen can be arrived at while the condition of the patient holds out a fair prospect of a successful issue; but in the first group the symptoms of intestinal obstruction are so intermingled with those of traumatic or septic peritonitis that an absolute diagnosis is exceedingly difficult, and the patient is generally so far gone before the surgeon considers himself justified in reopening the abdomen that all hope of relief by laparotomy has to be abandoned. Hirsch in his paper gives fourteen cases of intestinal obstruction following ovariotomy, and in only one (Case 8) was a secondary laparotomy done. This case was similar to that of Miss X——, in that signs of obstruction did not appear till late in the convalescence, and in that operation on the twenty-first day was followed by a successful result. With the increasing and more perfect knowledge of abdominal surgery, and with accumulating records of successful results, it is highly improbable that cases of the kind just quoted, in which obstruction has occurred late and signs of the accident are clear, will be allowed to die without an attempt being made to relieve them by surgical interference; but in those cases (which unfortunately form the majority) where symptoms of intestinal obstruction appear early and are complicated or masked by the presence of general peritonitis, either traumatic or septic, the surgeon will always be placed in a position of cruel uncertainty. Some may say that the abdomen should be opened in any case, as it enables us to search for and relieve an obstruction, should such exist; and, on the other hand, should septic peritonitis be present, it gives the opportunity for washing out the peritoneal cavity and inserting a drainage-tube. As regards this latter point, however, Mr. Alban Doran[2] remarks: "Judging from what I have seen, septicæmia, when it has once set in, is very unamenable to any active kind of treatment." My own experience is entirely at one with this statement; and while our surgical instinct renders us unwilling to leave a patient with actual mechanical obstruction unrelieved by operative interference, our past experience makes us yet more hesitating in using the knife in cases where further surgical proceedings may only hasten the end. In the group we have just been considering each case must be more or less a law unto itself; and in deciding the question of a secondary operation, the surgeon will be guided more by his surgical instinct, by the study of small details, and by his past experience, than by the formulation of any general rules.

The patient is now (October 28th, 1889) in admirable health, and is actively engaged in her ordinary literary pursuits.

A CONTRIBUTION TO THE

STUDY OF CHRONIC VALVULAR DISEASE OF THE HEART,

BEING

AN ANALYSIS OF ONE HUNDRED AND FIFTY CONSECUTIVE CASES SEEN AT THE GLASGOW ROYAL INFIRMARY DISPENSARY, WITH A SPECIAL LIST OF CASES BEARING ON THE INFLUENCE OF PREGNANCY IN CHRONIC VALVULAR LESIONS.

By GEO. S. MIDDLETON, M.A., M.D.,

ASSISTANT PHYSICIAN TO THE GLASGOW ROYAL INFIRMARY, ASSISTANT TO THE PROFESSOR OF PRACTICE OF PHYSIC IN THE UNIVERSITY OF GLASGOW, ETC.

(Concluded from p. 848.)

THE influence of pregnancy upon the prognosis in heart disease is a subject of very considerable interest, and one in which it is of importance to have definite grounds on which to form an opinion. I have recorded the cases of twenty-six women suffering from valvular disease, who had borne children, and a brief summary of these follows.

CASE 1.—Mrs. R——, aged thirty-eight. In 1869, four weeks after her first confinement, was treated in the

Digitized by Google

Glasgow Royal Infirmary for dropsy. During her residence the first hæmoptysis occurred; cardiac disease was detected at that time. During her second pregnancy she again had hæmoptysis, but not since that time. Three subsequent confinements were without trouble. The sixth was followed by dropsy; the seventh normal. The eighth pregnancy was complicated with dyspnœa and œdema of the lungs, and convalescence from confinement slow. She is again three months pregnant, and suffering slightly from dyspnœa. This woman has been under observation for four years, and presents the murmur of mitral stenosis in its most typical form. Last month, for the first time, the cardiac dulness was noted to be enlarged to both sides, and over the right ventricle a brief ventricular systolic murmur was heard. During these twenty years she has never for any considerable time been unable to perform her household duties—those of a labourer's wife. Whenever she feels the breathlessness increasing to such an extent as to threaten to interfere with her work—i.e., during pregnancies, she comes to the dispensary and improves at once on iron and digitalis. She never had rheumatism, rheumatic or severe growing pains.

CASE 2.—Mrs. M——, aged twenty-seven, came complaining of abdominal symptoms. Pelvi-peritonitis after parturition; very weak, and badly cared for. Accidental discovery of murmur of mitral stenosis. No spontaneous complaint of cardiac symptoms, but admitted having dyspnœa during last pregnancy; no cardiac symptoms under observation. No history of rheumatism. When last seen was apparently quite well.

CASE 3.—Mrs. M——, aged thirty-nine. Complaint: pains in head and back, and menorrhagia. Well-marked auriculo-systolic murmur. Subacute rheumatism after childbirth seventeen years previously, and less severe pains since. Has had several children since, and rheumatic pains are most marked after confinements. Has never had cough or spit, but has occasionally had dyspnœa on exertion, and palpitation when excited.

CASE 4.—Mrs. C——, aged forty-two. Complaint: shortness of breath, cough, and weakness. Well-marked auriculo-systolic murmur. No history of rheumatism, but "inflammation of lungs" six years ago, and frequent attacks of bronchitis and shortness of breath since then, with hæmoptysis three years ago. Five children, the youngest two years old. No history of special troubles during pregnancies.

CASE 5.—Mrs. H——, aged forty. Complaint: weakness and "choking." Had acute rheumatic fever seventeen years ago, eight months after first confinement. No recurrence of rheumatic pains. During seven subsequent pregnancies has had dyspnœa and cough; severe hæmoptysis during second and eighth, and occasionally at other times. Had not noticed dyspnœa and cough until within past few years, except during pregnancies. No œdema of the feet. Always recovered rapidly from confinements, but during last pregnancy (five years ago) was confined to bed almost all the time. Auriculo-systolic murmur at the apex. When seen she was decidedly ill.

CASE 6.—Mrs. H——, aged thirty-eight. Complaint: cough and hæmoptysis. Was well, save for slight cough, till two years and a half ago, when, during pregnancy, cough became worse and hæmoptysis occurred; no œdema. Recovered some time after confinement, but hæmoptysis has recurred. Is not pregnant. Auriculo-systolic murmur at apex. Rheumatic pains in childhood, but never so severe as to confine her to bed.

CASE 7.—Mrs. W——, aged twenty-eight. Complaint: dyspnœa, cough, hæmoptysis, and pain in left side. Typical murmur of mitral stenosis. Six attacks of rheumatic fever, the first eleven years, the last five months ago. Had palpitation since first attack; hæmoptysis only within past six months. Was married ten years ago, and is now pregnant with her seventh child. Was always well during her pregnancies, except during the last, when she had a discharge of blood for two months before the birth of a stillborn child at full time.

CASE 8.—Mrs. R——, aged fifty-two, Complaint: debility, diffuse pains, and heart disease. Has suffered from cough, slight spit (rarely bloody), dyspnœa, œdema, &c., at various times during many years past, and thinks that some of these first occurred shortly after a severe attack of rheumatic fever thirty-three years ago, when she was told that her heart was affected. Has had rheumatic pains since, but never severe. Had one child, without troubles during pregnancy or afterwards. When last seen seemed quite well. Well-marked mitral stenosis.

CASE 9.—Mrs. H——, aged twenty-seven. Debility, cough, and pain over heart and down the left arm, aggravated on coughing. Four years and a half ago, after an indefinite period during which she had been aware of pain in the left arm and of palpitation on exertion, she was suddenly, when at hard work, seized with hæmoptysis, not very copious. Since then precordial pain and troublesome cough, with frequent blood stains in spit. For two years has been scarcely able to do her household work. Had had two children prior to attack of hæmoptysis, without trouble during pregnancy or afterwards. Has since had three children, at full time, and has had hæmoptysis during each pregnancy. During last pregnancy had general anasarca, which persisted for a month after delivery, since which she has not regained her former health. Pure mitral stenosis discovered on examination. No history of rheumatic or growing pains.

CASE 10.—Mrs. McK——, aged thirty-two. Complaint: "lungs gone." Œdema at bases of lungs; dyspnœa, slight cough and spit; has often spit blood, first about eight years ago during pregnancy. Rheumatic fever seventeen years ago; no symptoms till eight years ago. Loud auriculo-systolic murmur, and perhaps also a brief ventriculo-systolic murmur at apex.

CASE 11.—Mrs. F——, aged forty. Repeatedly under observation for two years, and when last seen very ill with dyspnœa, cough, and general cardiac distress; well-marked double mitral murmur; never acute rheumatism, but severe growing pains. Dates cardiac condition to a period two days after seventh confinement nine years ago, when a fright induced severe dyspnœa, hæmoptysis, &c. Has had repeated similar attacks, and has never been quite well. Four children since; never very ill during gestation, no difficulty at confinement, but convalescence always tedious. Six months after last confinement had temporary right hemiplegia and aphasia.

CASE 12.—A. F——, aged thirty-two. Cough and hæmoptysis; mitral stenosis and regurgitation. Rheumatic fever at age of thirteen, and again eight months ago a slight attack; hæmoptysis nine months ago. One child six years and a half ago; very ill during pregnancy and long afterwards.

CASE 13.—Mrs. J——, aged thirty. Complaint: shiverings and hæmaturia of two days' duration. Double mitral murmur. Rheumatic fever at thirteen and fifteen years of age, and heart was under suspicion then. In eighth month of fourth pregnancy; three previous pregnancies normal. Never had dyspnœa till present pregnancy, but has had palpitation since marriage nine years ago. Slight hæmoptysis six weeks ago, and severe hæmoptysis a month after being first seen.

CASE 14.—Mrs. R——, aged twenty-nine. Left hemiplegia of four years' duration, but now only slightly marked, preceded by right hemicrania. No history of rheumatic fever, but has had "rheumatic pains." Has had palpitation. Three children before the seizure, one stillborn, one premature, and a third that died at four months of "nævus." One miscarriage since. Mitral regurgitant murmur and doubtful murmur of mitral stenosis. (History regarded as possibly syphilitic.)

CASE 15.—Mrs. B——, aged fifty. Complaint: dyspnœa, cough, sleeplessness, and pain in left side. Had cough and shortness of breath since she was a girl, especially in winter, but never confined to bed with these till ten or twelve years ago. Never had rheumatic fever, but slight rheumatic pains not infrequently. Six children, all born at full time and nursed by herself. During pregnancies great œdema of legs for last three months. A year ago hæmoptysis for first time, and frequently since. Marked auriculo-systolic murmur, and probably also ventriculo-systolic, at apex; very cyanotic and fingers clubbed.

CASE 16.—Mrs. M——, aged fifty-five. Complaint: general anasarca of several years' duration, with cough and dyspnœa, the cough dating thirty years back. Rheumatic fever twenty-one years ago, but never since. Aware that her heart is affected, but cannot give date of origin. Had two children since rheumatic attack, and suffered more with them than with previous eight. Marked mitral regurgitration. Very weak and livid.

CASE 17.—Mrs. McG——, aged twenty-six. Complaint: general anasarca of a week's duration, but with history of two previous attacks—the first three years and the second

Digitized by Google

eighteen months ago,—attributed to drinking, which she has indulged in to great excess for three years, so that each "spree" now ends in delirium tremens. Mitral and tricuspid regurgitant murmurs. Was married very young, and had her first child before she was fifteen, a second eighteen months later, and a third in other two years; all three living and healthy. About a year later had a miscarriage at the fourth month, and in rapid succession two others about the same period, and about three years ago a still-born child at eight months; has never been pregnant since. Always had hæmoptysis during gestation, but never œdema. Since she was fourteen has always had a cough, specially severe in winter; also great shortness of breath and palpitation since her third pregnancy. No history of rheumatic or other pains. Never had sore-throat or rash.

CASE 18. — Mrs. S——, aged forty-nine. Complaint: dropsy of limbs and body of a year's duration, with shortness of breath, palpitation, and debility. Mitral regurgitation. Severe rheumatic fever twenty-one years ago; no recurrence. Had several children before that, and five since. While pregnant with the latter seems to have suffered more from œdema of legs than on former occasions, but had no other trouble. Two years ago had severe hæmoptysis. While under observation had severe attack of melæna.

CASE 19.—Mrs. C——, aged sixty-two. Came complaining "of her heart"—palpitation, dyspnœa, cough, expectoration, and œdema of the legs. Tumultuous action of the heart, with hypertrophy of the left ventricle; mitral and tricuspid regurgitant murmurs, and a suspicion of an auriculo-systolic mitral murmur; great accentuation of the pulmonic second sound. Duration unknown; never had rheumatism or rheumatic pains. Had five children, and no trouble with any of them. [Very doubtful if cardiac disease was present during childbearing.]

CASE 20.—Mrs. McG——, aged thirty-five. Complaint: "dropsy"—œdema of limbs and ascites, with breathlessness, cough, and great lividity, dating from three months before the birth of her seventh child, three months ago. Four years ago, during her fifth gestation, had a similar attack with occasional hæmoptysis, and the sixth pregnancy was associated with similar, but less marked, symptoms. The last three pregnancies ended at the seventh month, as did also the first; but second, third, and fourth reached the full time. The first four pregnancies were not associated with dropsy or other troubles. Hypertrophy of left ventricle, with marked ventriculo-systolic murmur at the apex and a doubtful trace of auriculo-systolic; marked accentuation of pulmonic second sound. No history of acute rheumatism, but during second pregnancy had severe pains in legs and feet, confining her to bed for weeks, and has since been more breathless and more troubled with cough than formerly.

CASE 21.—Mrs. McJ——, aged thirty-eight. Complains "of her heart," precordial pain, dyspnœa, lividity, &c. Seven years ago had rheumatic fever, and has had slight attacks since. No cardiac symptoms till three years and a half ago, when, a week after the birth of her ninth child, she was suddenly seized with shortness of breath and hæmoptysis, ever since which she has had dyspnœa and palpitation. Has had ten children, the seventh eight months prior to the rheumatic attack, the eighth about two years later, the ninth as above, and the tenth about two years ago. She did not suffer more during the later than during the earlier pregnancies, and never unduly. Hypertrophy mainly of left ventricle; great irregularity of cardiac action; brief mitral ventriculo-systolic murmur, and probably also an auriculo-systolic; pulmonic second sound not much accentuated.

CASE 22.—Mrs. M——, aged twenty-two. Debility, cough with sputum streaked with blood, dyspnœa, and œdema of feet at times. One child, lately weaned. Aortic regurgitant murmur. Doubtful history of rheumatism.

CASE 23.—Mrs. G——, aged fifty-three. Cough, shortness of breath on exertion, and palpitation, said to be of only a fortnight's duration. At apex auriculo-systolic and ventriculo-systolic murmurs; at base double aortic murmur. Had rheumatic fever fifteen years ago, when carrying her sixth child, after the birth of which she had "inflammation of the side" with hæmoptysis. No recurrence of rheumatism or hæmoptysis. Has had a seventh child since, without any trouble. Left arm and hand much atrophied since twenty-eight years ago; onset with pain and "dumbness" in thumb; no injury.

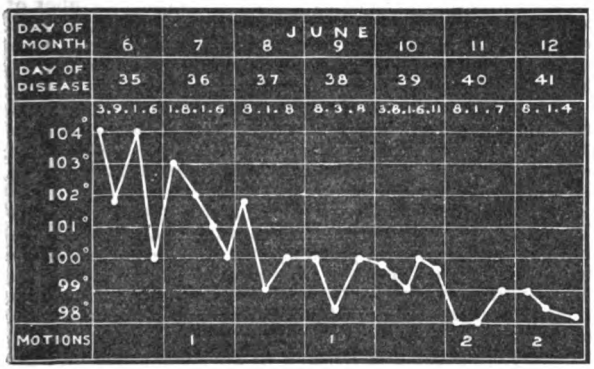
CASE 24.—Mrs. M——, aged fifty, complains of painful cramps in both legs and in left arm, of which she has had several attacks during the past fortnight, each lasting for a couple of hours or thereabout. Has had a cough during the past six months, with whitish sputum tinged with blood during the past six weeks, due, she believes, to epistaxis. Considered herself healthy till five years ago, when she got a fright and thereafter suffered from giddiness. Has never had marked dyspnœa, never had acute rheumatism, but suffered from rheumatic pains some three years ago. Marked double aortic murmur. Was married at fourteen and had twelve children.

CASE 25. — Mrs. G——, aged forty-eight. Complaint: palpitation, cough, and pain and swelling in the epigastrium. Double mitral murmur and double aortic murmur. Rheumatic fever ten years ago, and three recurrences. Since first attack shortness of breath, worse during the past two years. Since first rheumatic seizure has had two children, and was weak while carrying them, but had no special troubles.

CASE 26.—Mrs. N——, aged thirty-six. Complaint: precordial pain, headache, giddiness, palpitation, dyspnœa, and occasional hæmoptysis. Rheumatic fever twenty-six and twenty years ago, both bad attacks; occasional pains since. Nine years ago, three months after her first pregnancy, she fell from a height and was severely hurt; thereafter giddiness and dyspnœa. Two pregnancies since then, the last three years and a half ago, and had swelling of legs with both, but no hæmoptysis, which began only three years ago. Marked cardiac impulse with enlargement of dulness, but with slight thrill at apex. When first seen murmurs diagnosed as of mitral obstruction and regurgitation with probably aortic stenosis also, and exceptionally accentuated pulmonic second sound. When next seen, accentuation of second sound quite absent, and murmurs then unequivocally of aortic obstruction and regurgitation without suspicion of mitral lesion.

In only one or two of these cases does there seem to be any doubt that the cardiac lesion had preceded the birth of some of the children. Now, of these cases 9 were suffering from pure mitral stenosis, 8 from combined mitral stenosis and regurgitation, and 2 from pure mitral regurgitation; a total of 19 with pure mitral disease. Of the others, 2 had mitral and tricuspid lesion, 2 mitral and aortic, and 3 pure aortic disease. The great preponderance of cases of mitral lesion, and especially of mitral stenosis, is here very striking, and the histories of repeated pregnancies without much general disturbance, as seen, for instance, in a most marked form in Case 1, lead to the inference that the prognosis, even when pregnancy occurs, must in cases of that kind be regarded with considerable hopefulness. This view is entirely at variance with that expressed by the late Dr. Angus Macdonald in his book on "Heart Disease during Pregnancy," in which he gave it as his opinion that mitral stenosis was the most serious cardiac complication of pregnancy. It is, however, entirely in accordance with the general view of this lesion expressed above, and with the general tenor of Dr. Gairdner's teaching.

In regard to the general prognosis of cardiac valvular lesions, then, while admitting the gravity of all such affections, I would, from the experience I have had at the dispensary, incline to take a more favourable view than is often done. Even with regard to aortic incompetency, I am more hopeful than I once was, when I consider the condition of comparative health which many of the cases presented, their considerable duration, and the conditions under which the patients' lives were spent. For it must be remembered that almost all of these cases occurred among the very poor, whose circumstances were in all respects unfavourable from a prognostic point of view, and the great majority of whom, even when under observation, had to work hard for their living. In the more favoured classes of society, therefore, the prognosis ought to be all the better.



Treatment.—On this I have little to say, for the dispensary is not a suitable field for testing remedies, those who continue under observation not being able to carry out the general regimen ordered, and not being sufficiently under our control for the results of treatment to be carefully noted, while the more severe cases are always sent into hospital. In general terms, I may say that I have used both digitalis and strophanthus, especially in mitral disease, and such remedies as the iodide of potassium and nitro-glycerine in suitable aortic cases, with benefit. I need scarcely add that I have never regarded the mere discovery of a murmur as an indication for treatment.

TYPHOID FEVER; PERFORATION; RECOVERY.

BY GEO. A. BRANSON, M.R.C.S. &c.

A. B——, a professional nurse, aged twenty-six years, who was engaged from Melbourne to take care of a little typhoid patient early in April, complained to me on my evening visit (May 5th) that she herself had been "awfully bilious for the last two days." On examination I found she had a temperature of 104°, pulse 110, skin dry, and furred tongue. I told her that she probably had contracted typhoid, and that she must at once go to bed, and stay there. I ordered her hyd. subchlor. (gr. viii.) and pulv. jalap co. (gr. xii.), and sent for a woman to nurse her. (See Chart.) The chart shows, in a most interesting manner, the course her attack ran. The high rise of temperature on the seventh evening of the disease was due to excitement about the arrival of her great friend and fellow nurse from England, Miss Crabtree, whom I had telegraphed for to come up from Melbourne to nurse her. The only medicine I gave her, besides the powder above mentioned, were four minims of the tinctura veratri viridis every two hours until her pulse was below 100, until the tenth day of illness, when, her motions becoming very fetid, she took two grains of naphthaline night and morning for three days, with good result. She ran through an ordinary attack of typhoid upon strict milk diet until the twentieth day, when I was foolish enough to give way to her entreaties, and to permit her to

sit up in bed and to take a cup of chicken broth. For this nature severely rebuked us; her temperature that night went up to 101·4°, and the following night to 103·4°, and her pulse grew rapid again. She then developed phlebitis of the left femoral vein, with great pain, swelling, and stiffness in the thigh and leg; the pain and swelling subsided considerably in three days, but on the evening of the twenty-fifth day her temperature again ran up; pulse 115, weak, and easily compressible. Her tongue became very foul, so I put her on tincture of nux vomica and dilute nitro-hydrochloric acid, of each ten minims, to be taken three times a day, and half-ounce doses of brandy every three hours.

On the evening of the twenty-sixth day her temperature ran up to 103·6°, and, although she was freely sponged with cold water, at 8 A.M. the following morning it was 103·8°. Fifteen grains of antipyrin brought the temperature down a little, but depressed her considerably. On the twenty-eighth day she appeared to be better in every way; but as she was constipated I gave her an enema of ten ounces of hot water, and she responded with six semi-solid light typhoid-coloured stools; her temperature and pulse both ran up again at night, and the following morning her temperature was 104° and her pulse 130. No pain anywhere; she was quite sensible and cheerful, and took the brandy and milk well. The following morning, thirtieth day, she complained of feeling sick after the milk, so I ordered her whey instead; she passed two motions during the morning and one in the evening—small ones with nothing abnormal; but her pulse was very threatening, 140 per minute, and weak, so I put her upon carbonate of ammonia, tincture of digitalis, and sulphate of ether. The following morning, thirty-first day, she again complained of feeling very sick, with considerable pain in the right cæcal region; tongue heavily furred, but not dry; respiration short and hurried, pulse 130, temperature 103°. I ordered hot fomentations to the abdomen, and at midday went back to see her, and found the pain in the abdomen almost gone, the skin covered with cold clammy sweat, pulse imperceptible at either wrist, temperature 104°, abdomen commencing to swell, violently sick and retching; hiccough also present. Heart beating 145 per minute. As the patient had not a single relative in Australia, I told her friend the nurse I was of opinion that perforation of the bowel had taken place, and that the patient might last six hours. Fortunately they were living close to my house, and I could see the patient frequently. At 5 P.M. her temperature was 105°, abdomen much more distended, breathing very shallow and rapid; kept poppy fomentations and a binder on abdomen; pulse imperceptible, patient quite sensible, felt cold, and kept vomiting terribly. No ice could be obtained in the district. Ordered her enemas of brandy and beef-juice every three hours. At 10 P.M. her temperature was down to 100·2°; still pulseless at wrists; heart beat 130. Skin cold and clammy; retching continued, but retained enemas well. Breathing very spasmodic, entirely thoracic. She said her throat was suffocating her. I gave the nurse a bottle of chlorodyne, and directed her to give the patient twelve to fifteen minims very frequently, if restless, either by mouth or rectum; abdomen greatly distended. At 1 A.M. on the thirty-second day her temperature had fallen to 98°. Abdomen intensely distended, pulse imperceptible; still cold sweat and retching. Ordered hot-water bottles to be put round her, to push the chlorodyne and brandy, and gave her eight grains of carbonate of ammonia, which she quickly ejected. I gave her a hypodermic syringeful of rectified ether, and directed the nurse to give her a syringeful of brandy and ether alternately every half hour; absolutely nothing by the mouth. My prognosis was that she would be dead before daylight; but, on returning at eight next morning, I found that my patient had slept three hours and a half, and although her temperature had been subnormal all night, she was no worse than she was seven hours previously. To continue with the brandy enemas and brandy-and-ether hypodermic and chlorodyne. At 1 P.M. her temperature was up to 99°, but she was weaker, and took less notice of my visit than formerly; from 5 P.M. until midnight she was sinking fast, delirious, pulseless, cold sweat, and intense abdominal distension; could not count her heart beats; still retching violently. On visiting her at eight o'clock next morning (thirty-third day of disease) I found she had slept for a few hours, and had lost the delirium and cold sweat; temperature 102·6°; still retching; pulse at wrist 130; abdomen same as yesterday. Ordered the nurse to continue the brandy enemas, to apply mustard to the stomach, push chlorodyne and ether, and to give half a drachm of oil of turpentine every three hours. Her temperature at 5 P.M. was 104·4°, but her pulse was stronger, and she was not so sick as she had been; no pain whatever. At 1 A.M. the following morning her temperature was 104·8°, but at 11 P.M. it was 102·5°, and she was decidedly better; less sickness, pulse stronger, abdomen still intensely distended. The following day her temperature varied from 104° in the morning to 100° at night, and she was improving splendidly; tongue foul, but no sickness or retching; no pain; less distension; took and retained a little brandy-and-milk by the mouth. To keep on taking chlorodyne, and to take eight grains of bicarbonate of soda and half a drachm of spirit of ether every three hours.—Thirty-sixth day: Slept well last night; tongue cleaning up; abdomen going down; pulse 110, and much stronger; no sickness, so gave her some raw beef-juice and brandy, and, as she had not passed any motion for more than five days, I ordered her a small enema, which pained her considerably, but acted once very efficiently. From this time onwards she improved very rapidly. Her next motion, on the thirty-eighth day, contained a number of small sloughs, and was remarkably offensive. Abdomen getting quite retracted. On the fortieth day she passed a slough fully six inches long by half an inch in diameter; very foul odour. She then made an uninterrupted recovery, and could walk about before returning to Melbourne on June 28th.

I must apologise for these somewhat rough notes. They were hurriedly made in a busy time of a large Bush practice, and with no intention of publication; but there are many points which appear to be of great interest. Was

Digitized by Google

the relapse on the twentieth day due to my allowing her to sit up and to have chicken broth? I fear so; and yet this rise of temperature might be due to the phlebitis of the left femoral vein; for although the temperature went up to 101·4° that night, and the following evening to 103·4°, yet the next three nights it was not high. There can be little doubt that actual perforation of the gut took place, followed by peritonitis with efficient adhesions. Bristowe, writing of perforation, says: "Death almost invariably follows this lesion, and generally occurs within a couple of days, sometimes in the course of a few hours." I had one other case of perforation this year which proved fatal sixty-eight hours afterwards. I attribute the patient's recovery to the splendid nursing she received, to her own great pluck, to peritonitis, to keeping the bowels quiet with opium, and to the hypodermic injections. Although the actual perforation may have been small, yet the amount of tissue destroyed was immense. Naphthaline answered well as an internal deodorant and disinfectant; I have also used for this purpose iodoform dissolved in sulphate of ether, then mix with vegetable charcoal, evaporate the ether, and mix with glycerine.

Tungamah.

LEPROSY IN KASHMIR: ITS DISTRIBUTION AND ETIOLOGY.

BY ERNEST F. NEVE, M.D., F.R.C.S. ED.,
SURGEON TO THE MISSION HOSPITAL.

FOR my purpose the country of Kashmir may be subdivided into:—1. The valley proper—a tract about fifty miles by thirty, comparatively level, bisected by the river, containing several large sheets of water—one, the Woolar, being the largest freshwater lake in India. In the centre of the valley is the city of Srinagar. 2. The tributary valleys, averaging thirty to forty miles in length, comparatively narrow, leading down by steep gradients from the great watersheds. 3. At the heads and sides of these valleys, and also at an elevation all round the main valley, are the uplands and mountain pastures. The population, which is less than half a million, may be grouped as A, urban; B, agricultural; C, fishing; D, herdsmen. In Division 1 of the valley we have Groups A, B, and C. In Division 2 Groups B and D. As we penetrate into the mountains the latter group ever increases.

Now, let us glance briefly at two points—viz., the diet and the distribution of leprosy. Speaking generally, the diet of Groups A and B is rice, a great assortment of vegetables and fruit, meat, milk, and a certain amount of fish. The diet of Group C would be somewhat the same, but includes a very large amount of fish, especially in the case of the boating population around the Woolar lake, to whom fish is a staple article of diet, both fresh and dried. There is a small dried fish industry, and fish thus prepared is sent up to the city. The diet of Group D is largely composed of milk and milk products. To a less extent the herdsmen eat the other articles above mentioned; but from fish they are cut off, from their position, being usually far removed from the lake and river, while the snow streams do not contain fish. Lepers are rather numerous in Kashmir. During the past year we have seen eighty-six as out-patients. Of these, at different times, forty-four have been admitted as in-patients into a special ward. Notes have been taken of many of these cases, but chiefly with regard to their condition and treatment. I have drawn up a table of lepers seen, with the exception of five, within a fortnight. An analysis of this will illustrate some points in distribution and etiology.

The prevailing type is mixed tubercular and anæsthetic leprosy. The number of cases twenty-two; the majority males. Of these eleven were from Division 2 of the valley, six from Division 3, two from Divisions 2 to 3, one from Division 1, while two were unknown. With regard to population groups, one was from Group A, twelve from Group B, none from Group C, three from Groups B, D, four from Group D, while two were unknown. Nine gave a history of other lepers existing in the district or village from which they came; seven denied the presence of other lepers there; six were uncertain whether there were or not. Fifteen stated that absolutely none of their relatives had the disease; one said his mother was affected; in the case of another, one sister only was leprous; a third stated that only his mother and one sister were diseased; in the case of a fourth, only an uncle was affected; another patient gave a history of his grandfather being a leper, but his father not; and, finally, one had a brother a leper. In the case of one, the condition of the relatives was unknown. Interrogated as to fish diet,[1] nine had eaten fish frequently, two occasionally, one perhaps in infancy, five never. With regard to the remaining five I have no record.

Now this analysis suggests several interesting considerations:—

(*a*) A preponderance in males. We do not see many female lepers. According to our books, the percentage of this sex does not exceed 16.

(*b*) We note that Division 2 of the valley contributes rather more largely than the others. This is partly due to its proportionately large population; then in the winter the people from Division 3 come down into the neighbourhood of Division 2; yet I am inclined to think that if the table had embraced a larger number of cases that Division 3 would be found to contribute the largest number of lepers—viz., from amongst the herdsmen of the country.

(*c*) The question of the existence or not of other lepers in their district is one on which the testimony of patients is not worth much, as signs in others are often slight and intentionally concealed.

(*d*) With regard to relatives their testimony is more valuable, because living in the same house they have opportunities of judging. The result of the inquiry is interesting as affecting the question of heredity and contagion. It is a striking fact that in so many instances no other member of the family was affected, as is also the way in which individuals are selected by the disease, and occasionally a generation is skipped. Certainly we should not get such a clean bill of health in the case of the tubercular diathesis. I have examined the near relatives myself in several cases, and satisfied myself as to their freedom. It is the same with regard to their offspring. One patient informs me that his wife, son, and two daughters have all been constantly living with him till recently, yet all are healthy.

(*e*) In any country where fish is abundant, of course it forms an article of diet. If the questions had been about milk, or rice or mutton, probably every member would have answered in the affirmative. It is a very significant fact that not a single member of Group C, the fishing population, is to be found on my list. Indeed I do not remember ever having seen a leprous boatman.

Contagion.—There is nothing in Kashmir which can be said really to favour the idea of contagion. The histories of the above patients are rather against it. Still, one is confronted by the question, If leprosy is neither hereditary nor contagious, why does it not die out? I feel that the grouping of the lepers is important. When travelling in the different parts of the valley, if in a given district one leper is found, others will not be far distant. This tends to indicate certain endemic propensities. Again, the fact of heredity being apparently not a very strong factor in reproducing the disease tends to make communicability more probable.

If leprosy is contagious, it is so either by (1) aerial transmission, (2) inoculation, or (3) diet. The first appears opposed to all one's experience. The second, as far as Kashmir is concerned, has never been proved, although the leprous bacillum has been found present in the discharges. If contagion occurs, it must take place only under favourable circumstances. Surgeons who do the operation of nerve-stretching on lepers do not escape an occasional prick of the fingers. But so far the inoculation experiment has, I am happy to say, failed. Intermediate transmission by flies from wound to wound, or even by mosquitoes, does not seem impossible. Vaccination is not sufficiently practised to be, if done carelessly, a possible source of contagion. Thirdly, diet, including water. Recent researches with regard to milk and tuberculosis direct by analogy one's attention to diet. We must eliminate actual inoculation, due not to diet but to contaminated eating vessels. Diet, I take it, may be at fault, either as a predisposing cause or as containing actual virus. As a predisposing cause, food insufficient or poor in quality and wanting in variety would be apt, speaking generally, to predispose. With regard to actual virus in

[1] See Hutchinson: THE LANCET, vol. i., 1879, p. 230; Brit. Med. Jour., vol. i., 1889, p. 1449.

Digitized by Google

the diet, this might be present as (1) the specific organism of leprosy arising *de novo* in certain diet substances; or (2) another bacillum might, under suitable conditions, become changed in its nature and tendencies, and become leprous; neither of these views seems probable, or indeed in accordance with bacteriological laws; (3) from actual contamination, as by a leper washing in a tank, and the water of that being drunk or mixed with food, as, for instance, in the adulteration of milk; or again (4) it is possible that under certain conditions the bacillum might propagate itself if once planted in a suitable medium, as, for instance, milk, milk cheese, or dried meat, so that these, when ingested, might reproduce the disease in those who are predisposed.

(To be concluded.)

PERCHLORIDE OF MERCURY IN DYSENTERY.

BY K. P. CHOWDHOVRY,
ASSISTANT SURGEON, MEDICAL OFFICER IN CHARGE OF THE BURDWAN CHARITABLE HOSPITAL.

DYSENTERY is a disease which prevails most extensively in various malarious tracts in India. It has been the scourge of the Indian army, and is the principal cause of death among the famine-stricken, ill-fed, and improperly clothed poorer classes of the people of this country. It occurs in the most virulent form among the poor pilgrims who travel by the Grand Trunk Road from the North-western Provinces to the Temple of Juggernaut in Orissa. When it occurs among the Europeans it is very generally found to be obstinate. On account of this they are often required to undertake long journeys to distant and salubrious climates to recover their health. It is therefore of the utmost importance to find out any medicine which could be useful in so dreadful a disease. The discovery of ipecacuanha certainly produced a new era in the treatment of dysentery. A very large number of cases that used to die yearly in the Indian army from acute and chronic dysentery began to be saved by the introduction of this remedy. Large doses of ipecacuanha became for a time the only treatment of dysentery in both the acute and chronic stages. The high authority of Dr. Maclean sanctioned this as the only rational treatment, and for a time the profession held up this as the most suitable means of controlling the dreadful ravages of the terrible disease. The practice, however, in the civil hospitals and among the people generally began after some time to change. The ipecacuanha treatment was found unbearable in many cases, and the constant sensation of nausea which worried the patients undergoing such treatment interfered very greatly with their taking nourishment. Smaller doses of ipecacuanha are more easily retained, and on the whole they produce less inconvenience to the patients. I have found smaller doses (3 gr. to 5 gr.) in combination with soda and acacia very useful in acute cases of dysentery. But in the treatment of the chronic varieties every remedy seemed to be equally useless. Thousands of cases of this fell disease have been treated in the Burdwan Charitable Hospital within the last five or six years, and to my knowledge a very large number of them died, notwithstanding every kind of recognised treatment. Thinking that ipecacuanha owes its efficacy to the power it possesses of stimulating the liver and producing an abundant secretion of bile, I resolved upon perchloride of mercury as a mineral which would serve the same purpose, without the nauseating effects of the former. Having lately read of the wonderful efficacy of perchloride of mercury in Hill diarrhœa, I felt inclined to try the effects of the same drug on dysentery. My expectations were fully realised, and I found that under this treatment some of the most hopeless cases of the chronic type were cured within a comparatively shorter time than what could have been expected under any other method of treatment. I have treated many cases in this way, and I may say with almost uniform success. To avoid being wearisome, I shall content myself with a short account of only three cases.

CASE 1.—Makhan Lall Roy, aged thirty-two, a Hindu male, and a cook by profession, was admitted into the Burdwan Charitable Hospital on March 25th, 1889. He had been suffering from dysentery for the last three months. He used to pass mucus and blood in his stools, and he was troubled much with griping and straining. Five minims of the liquor hydrargyri perchloridi in two drachms of water were prescribed, to be taken every four hours. On the 28th there was very little blood and no mucus in his stools. On the 29th he was quite well and left the hospital. This was a case of marvellous recovery.

CASE 2.—Runnoo Ogha, aged thirty-eight, Hindu male, a priest by profession, was admitted into the Burdwan Charitable Hospital on April 26th, 1889. He had been on his pilgrimage to Juggernaut and was returning home. He had been suffering from dysentery for the last seven or eight days. He used to pass about twenty stools a day, with an abundance of blood and mucus. He complained much of griping and straining at stool. I prescribed five minims of the liquor hydrargyri perchloridi in two drachms of water every four hours. The colour of the stools was changed in two or three days; they became greenish, and there was no more blood in them. The stools gradually became yellowish and much thicker in consistence, and ultimately natural. The man was cured and discharged from hospital on May 12th, 1889.

CASE 3.—Zulsa, aged forty-five, a Hindu, was admitted into the Burdwan Charitable Hospital on June 26th, 1889. She had been suffering from dysentery for nearly a whole month. She used to pass blood and mucus in her stools. I prescribed five minims of the liquor hydrargyri perchloridi in an ounce of water, to be taken every four hours. She rapidly recovered under this treatment, so that on July 1st, the sixth day after her admission, she was quite well, and was therefore discharged from hospital.

Burdwan.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

TREATMENT OF WHOOPING-COUGH BY EUCALYPTUS SPRAY.

BY WM. W. HARDWICKE, M.D., M.R.C.P., &C.,
MEDICAL OFFICER, HARWICH BOROUGH AND PORT.

DURING an epidemic of whooping-cough which occurred last year in this district, I was induced by the continual failure of the various popular remedies, such as alum, belladonna, atropine, &c., to effect cures, to try the effect of the oil of eucalyptus. The extraordinary power of infection which is characteristic of this disease—due no doubt to the ease and rapidity with which the infected particles are thrown off in the act of coughing, and are carried to the air passages of others more or less susceptible—suggests to us that the true remedy for this disease is one of an antiseptic nature. This fact has been recognised for some length of time, and carbolic acid has been used for the purpose in various forms, with more or less success. But it must be acknowledged that not only is carbolic acid an imperfect antiseptic, for Ringer tells us that "no satisfactory proofs exist of its capability to destroy the contagious elements of disease," but it is a dangerous drug even in a diluted form to be left about amongst children and nurses. Its offensive smell to the majority of people, and its unpleasant associations, render its use for any length of time undesirable. Eucalyptus oil is, on the other hand, a powerful antiseptic, being more than three times as strong as carbolic acid in preventing the development of bacteria, has not the caustic properties of the latter, and does not produce that irritation which the latter does, even when diluted, on the lips or mucous membrane. In combination with terebene the oil forms a mixture having a pleasant aromatic odour, somewhat similar to sandal wood, exercising a sedative influence on the lining membrane of the air passages, and possessing, besides antiseptic properties, the power of destroying the virus of the sputum, which is not only found clinging to the thickened and congested mucous membrane of the epiglottis, larynx, and bronchi, but is with every fit of coughing ejected by the mouth, with the possibility of infecting others. This sputum being crowded with bacteria

Digitized by Google

and micrococci, it is upon the destruction of these with their extraordinary power of development and multiplication that our success depends. For this purpose I use the following mixture as a spray: Oil of eucalyptus, two drachms; terebene, two drachms; rectified spirit of wine, one ounce and a half. When used, the spray machine is held at a short distance from the mouth, which is opened to receive the spray. I generally order it to be used half an hour before each meal and at bedtime, thus ensuring a constantly ozonised breathing atmosphere. Internally I give terebene in drop doses to a child of from one to three years of age in combination with two grains of carbonate of magnesia and ten minims of compound tincture of camphor to one or two teaspoonfuls of water, repeated every three hours. The two former constituents to be triturated together, the magnesia being used simply as a carriage for the terebene, which is not miscible with water. The paregoric allays the irritability of the cough until the disease succumbs to the specific treatment. The machine I usually recommend for spraying is an ordinary odorator. A cheap form is one represented in Fig. 183, Sec. VI., in Maw's Catalogue, and can be used either with or without bellows. In every case where the above treatment has been properly carried out I have effected cures in about a fortnight. About a week after the characteristic "hoop" has become developed the paroxysms gradually become reduced in frequency and violence, until they cease to be noticed at all.

Dovercourt.

DISLOCATION ON TO THE DORSUM ILII IN A CHILD SIX YEARS OLD.

By C. LYNE DIXSON, M.B., M.R.C.S.

IN reading the case recorded in THE LANCET of Oct. 12th of dislocation on to the dorsum ilii in a child seven years old, which occurred at the Taunton and Somerset Hospital, under the care of Mr. Farrant, I was reminded of a similar case which came under my notice two years ago.

Riding one evening through a village on the North Tyne, I was suddenly called into a cottage to see a little girl, six years old, who had fallen out of the back of a cart, with her leg bent under her as she fell—at least, so the story was told. On examination, I found a distinct dislocation of the head of the right femur on to the dorsum ilii. She seemed in great pain and distress, and would not let me handle the limb at all. As in the case recorded, the thigh was semiflexed, adducted, and rotated inwards, the great toe resting on the dorsum of the left foot. As the pain seemed excessive and the child was very nervous and frightened, I returned for some chloroform; then, by the light of a candle and with the aid of the mother, I placed the child on the floor on her back, with only a pillow under her head. Having administered the anæsthetic, I removed my left boot, and placing my foot on the right ilium, I made extension of the right leg by pulling the limb at right angles to the body. Immediately the bone returned to its place with an audible click. An outside splint and a fortnight in bed, and the child was sufficiently well to get about; at the end of a month she was as well as ever.

I have recorded this interesting and rare case owing to its very close resemblance to the one I have already referred to, the only difference being that the patient was of the other sex and a year younger, and the right limb, instead of the left, was the one affected. The treatment I adopted was not the same, but the result was equally good.

Llantwit Major, S. Wales.

EXPERIMENTS ON THE ACTION OF SYZYGIUM JAMBOLANUM IN ARTIFICIAL DIABETES.

By DR. C. GRAESER.

I HAVE recently had the opportunity, through the kindness of Professor Binz, of making, in the Pharmacological Institute at Bonn, some experiments with extracts of the fruit of syzygium jambolanum upon dogs rendered diabetic by phloridzin. The plant is a tree of the group Eugenioideæ, subfamily Myrteæ, indigenous in tropical America, the West and East Indies, where its acid fruit is eaten. When at Java I learnt that the plant is called "djamelang" by the natives, who use the fruit and bast for diarrhœa and diabetes. Since its introduction into Europe as jambul it has also been here employed in diabetes.[1] In order to test its action more carefully, and to see whether and to what extent it may influence artificial diabetes, or what toxic effects it may possess, I made some dogs diabetic by phloridzin, following the instructions of von Mehrung.[2] By administering from 2·5 to 4·8 grm. of phloridzin daily to young dogs (weighing 2700 to 4800 grm.) in the proportion of 1 grm. per kilo of body-weight, there ensues an excretion of sugar lasting for twenty-four to thirty-six hours, and amounting to from 5·89 to 12·45 grms. At first I gave the phloridzin in one dose, later in gramme doses every two or three hours, without any notable difference in the amount of sugar excreted. In three experiments some diarrhœa was set up. In each case, whenever either before, with, or after the phloridzin, the animal was given extract of syzygium jambolanum, the sugar excretion invariably fell, in some cases to about nine-tenths of the amount excreted under phloridzin alone, in all it was diminished to at least one-half. At the same time the period of excretion was curtailed. Thus whilst with phloridzin alone the amount of sugar was from 5·89 to 12·45 grm., the amount (with the same dose of phloridzin) under treatment by jambul was maximum 2 906, minimum 1·5 grm. With a drug of which the action begins and ceases within a limited time, its antidote must also act in a definite time and in corresponding quantity, to be determined by experiment. So that if such a diminution in the excretion of sugar takes place as related in these experiments—viz., nine-tenths—by the use of jambul, its more accurate employment might perhaps completely check this excretion. The conditions in diabetes mellitus are far better suited to test this, besides showing the agreement between phloridzin diabetes and the natural disease. This research is of special value as showing that the syzygium jambolanum may be used in diabetes mellitus in the human subject much more freely and in larger doses than hitherto, for in no direction were any effects observed which would contraindicate its use. There was no sign of any toxic action even in the dog which had a daily dose of jambul extract. In one experiment there occurred some diarrhœa, but this happened in later experiments with phloridzin alone, and was probably attributable to the latter. In all the experiments extracts of the syzygium jambul were used which had been prepared by R. H. Davies, F.I.C., of the Society of Apothecaries, London, from fruits I had brought over with me. The extracts were partly made from the whole fruit, partly from the rind or kernel, and concentrated so that 100 grm. of fruit were represented by 16⅔ grm. of the kernel and 11⅔ grm. of the rind extract. The dose was 6 to 18 grm. daily. It is still uncertain whether the active principle is in the rind or the kernel—probably in both, but more in the former.

The results of three sets of observations may be thus summarised:—

	Grms.	Grms.	Grms.
Sugar excreted with phloridzin ..	12·5	10·0	10·5
Sugar excreted with phloridzin and jambul	2·1	1·0	1·5
Percentage reduction in sugar ..	80·8	84·0	85·7

Bonn.

POISONING BY PHOSPHORUS.

By SAMUEL GROSE, M.D. ST. AND., F.R.C.S. ENG.

A GIRL, aged three years and a half, ate some phosphorus paste. There was slight sickness at first, little or no pain, no fever, and yet constant thirst; apathy, gradually deepening into convulsions and coma; jaundice with white stools; dribbling of coffee-grounds-like fluid from the mouth; and death on the fifth day.

After death the liver was found much enlarged and in a state of acute fatty degeneration. Heart and kidneys felt greasy on section. On the third and fourth day, the urine gave no deposit on boiling or on addition of nitric acid, but it reduced the copper in Fehling's solution. May the presence of sugar in urine help to distinguish between those poisoned by phosphorus and sufferers from acute yellow hepatic degeneration, the symptoms in both being very similar?

[1] See Bernhard Schuchardt, Centralbl. für Klin. Med., 1889, No. 23.
[2] Verhandl. der Kongr. für Innere Med., Wiesbaden, 1886

Digitized by Google

The disease in question is misnamed "acute atrophy of liver"; here the liver was immensely enlarged. The little patient died when it was hypertrophied; had she lived longer it might have atrophied. Phosphorus is classed amongst the irritant poisons. In this case it gave rise to little vomiting, less pain, and no inflammation of throat, stomach, or intestinal canal. The action was more that of a blood poison, as if

"....The life of all his blood
Is touched corruptibly."

ANTIPYRIN: RESULTS FOLLOWING ITS ADMINISTRATION.

By W. WATKINS, L.R.C.P., M.R.C.S., &c.

As Dr. Adolphus J. Richardson has drawn attention to some of the (apparent) bad effects of antipyrin in THE LANCET of the 19th ult., the following case may be of interest.

Miss W. G——, aged thirty-seven, during a slight attack of gastro-intestinal catarrh with jaundice, complained of a severe nervous sick-headache in the course of the illness. I prescribed ten grains of antipyrin, which entirely removed the ache, but within half an hour the upper lip had greatly swollen, and continued to do so for another quarter of an hour, by which time it was at least double its normal size. The swelling disappeared almost as rapidly as it came, and in three hours from the time of taking the drug the lip was its natural size. There was no other apparent cause operating.

NORTH-EASTERN HOSPITAL FOR CHILDREN.

FOUR CASES OF STONE IN THE BLADDER IN MALE CHILDREN; REMARKS.

(Under the care of Mr. BILTON POLLARD.)

THESE cases are examples of successful operation for the removal of stone from the bladder by means of operative procedures, which are now frequently employed in the case of young children. We have published cases in the "Mirror"[1] during the last two or three years illustrating the facility with which lithotrity can be performed at a very early age, and it is generally accepted that either of the methods illustrated by Mr. Pollard's cases may with advantage be substituted for the rapid and frequently brilliant operation of lateral lithotomy. Surgeon-Major Keegan published in the *Indian Medical Gazette* of last year a series of 114 lithotrities performed by himself and others in young boys, some of them operations for large stones. The mortality was only 4 per cent. Surgeon-Major Freyer,[2] amongst his list of 100 cases recently published, gives sixteen successful operations by lithotrity in male children. We have so recently drawn attention to the operation of supra-pubic lithotomy, that we refer our readers to our remarks already published.[3] For the notes of these cases we are indebted to the house-surgeons, Messrs. de Chazal and Brock.

CASE 1. *Lithotrity; cured.*—L. F. W——, a boy aged three years, was admitted on Dec. 19th, 1888. He had had symptoms of stone in the bladder for seven weeks. Five weeks ago he was circumcised at another hospital. On admission micturition was frequent and painful; the urine was strongly alkaline and deposited muco-pus and triple phosphates. A stone was detected by the sound, and by rectal examination it appeared to be about the size of a small almond. On the twelfth day after admission the boy was anæsthetised with chloroform, and the stone crushed with a No. 8 lithotrite and the fragments washed away through a No. 8 evacuator. The dried fragments, which were composed chiefly of phosphates, weighed only ten grains. The temperature remained normal after the operation. The child was discharged four days later. He was relieved of his symptoms, but there was still a little pus in his urine. He was readmitted ten days later because his urine was again alkaline and still deposited pus and phosphates. No fragments of stone could be detected. The bladder was washed out with boracic lotion, and the child was kept in bed. On the ninth day after readmission the urine was clear and acid. He was allowed to get up on the twentieth day, and was discharged cured on the twenty-eighth day.

CASE 2. *Lithotrity; cured.*—S. S——, a boy aged two years and five months, was admitted on Feb. 1st, 1889. He had always had difficulty in passing his urine, and on this account he had been circumcised five months ago. Four months ago he passed some blood with his urine, and latterly he has complained of pain after micturition, and has pulled and scratched his penis a good deal. On admission he cried after passing urine, and frequently wetted the bed. A small stone was detected by combined rectal and supra-pubic examination. The urine was alkaline and contained a little pus and triple phosphates. The child had some bronchitis, so the operation was deferred until the fifteenth day after admission. He was put under the influence of chloroform, and four ounces of boracic lotion were injected into the bladder. The stone was crushed with a No. 5 lithotrite, and the fragments washed away through a No. 6 evacuating catheter. Difficulty was experienced in removing all the fragments, and as the child's pulse began to fail some of them were left in the bladder. The child passed his urine twelve times during the night. Micturition was painful. Some small fragments of stone were found in the urine. On the day after the operation the temperature reached 100° F., but by the fourth day it was normal. The urine contained a little mucus, but was otherwise normal. The child was discharged cured on the fifth day after the operation. The stone was phosphatic, and the dried fragments weighed thirty grains.

CASE 3. *Supra-pubic lithotomy; bladder sutured; primary union; death from malignant scarlet fever.*—W. S——, a boy aged seven years, was admitted on Dec. 15th, 1888. Symptoms of stone in the bladder had been present for three years. Circumcision had been performed a year ago at a country hospital. On admission, alkaline muco-purulent urine constantly dribbled from the urethra, and the boy suffered from continuous pain. A large stone was felt with the sound and by rectal examination. The bladder was washed out daily with boracic lotion, and on the fifth day after admission the urine was neutral and contained a slight deposit of muco-pus. On the seventh day supra-pubic lithotomy was performed. The bladder was distended with an ounce and a half of boracic lotion; no more could be introduced into the viscus. The rectal bag was used. The incision into the bladder was an inch and a quarter in length. The stone was tightly held by the small bladder, and some difficulty was experienced in extracting it. The stone, after drying, weighed 562 gr. The bladder was repeatedly flushed out with boracic acid lotion. The wound was sutured with ten fine silk stitches, which were inserted according to Lembert's plan. The efficiency of the sutures was tested by distending the bladder with boracic lotion. The lotion flowed back by the side of the catheter, but none escaped from the wound in the bladder. The wound was washed out with 1 in 20 solution of carbolic acid. The recti muscles were sutured with silk at the upper part of the wound. The skin was sutured, except at the lower part of the wound, where a tube was inserted between the recti muscles. The wound was dressed with boracic acid powder and sal alembroth gauze and wool. No catheter was left in the bladder or passed subsequently. The boy voided his urine naturally. No urine escaped from the wound. The boy was completely relieved from pain. The drainage-tube was removed on the fourth day after the operation, and on the eighth day the wound appeared to be soundly healed. Until the ninth day after the operation the temperature ranged between

98° and 98·8°, except on the first, third, and fourth days, when 99° was registered; on the eighth day the highest temperature was 98·6°; on the ninth day it suddenly rose to 102°. The boy had also a sore-throat and a typical scarlet fever rash. He was sent to the Homerton Fever Hospital, where he died two days later in a typhoid condition, and with a temperature of 103·4°. There was nothing further to note with regard to the bladder or the operation wound.

CASE 4. *Supra-pubic lithotomy; bladder sutured; leakage of urine on three occasions; rapid healing and cure.*—A. L——, a boy aged five years, was admitted on Sept. 18th, 1889. About three or four months ago the child began to suffer from painful micturition, which was often involuntary and accompanied by prolapse of the rectum. Blood had never been noticed in his urine. On admission the urine was acid and deposited a little pus. By rectal examination a hard mass, which appeared to be as large as an unpeeled walnut, was felt in front of the rectum just within the anus. On the third day after admission the boy was placed under the influence of chloroform, and the stone, both by sounding and by rectal examination, was felt to be fixed at the neck of the bladder. A catheter could not be passed beyond the stone, and so it was impossible to distend the bladder, but the latter contained a few ounces of urine. Supra-pubic cystotomy was performed. The rectal bag was not used. The incision in the skin was an inch and a half long and that in the bladder about an inch and a quarter. The stone was found to be dumb-bell shaped, one end being impacted in the prostatic portion of the urethra and the other projecting into the bladder. By pressing on the stone from the rectum whilst the neck of the bladder was pushed off it by the finger in the bladder the stone was disengaged and then readily extracted with forceps. The bladder was washed out with boracic acid lotion and the wound in it closed by eight ordinary interrupted sutures, which were passed through the muscular coat only. The efficiency of the sutures was tested by injecting the bladder with boracic acid lotion. Some of the fluid returned along the side of the catheter, but none escaped from the wound in the bladder. The superficial wound was mopped over with 1 in 500 solution of perchloride of mercury. The skin was brought together with silk sutures except at the lower part of the wound, where a drainage-tube was inserted. A dressing of boracic acid powder and sal alembroth gauze and wool was applied. The dried stone weighed 215 grains. Six hours after the operation, as the boy had not voided any urine, an indiarubber catheter was passed and an ounce and a half of urine drawn off. Owing to a misunderstanding the catheter was not passed during the following twelve hours, and during this time the bladder became so distended that one of the sutures gave way, and urine escaped freely into the dressing. The lower part of the skin wound was opened up, and a wet boracic lint dressing applied. The catheter was now passed every four hours. On the fifth and tenth days after the operation a little urine escaped from the wound. On the fourteenth a catgut suture which had been used for stitching the bladder was found loose in the wound. Two ounces of urine were passed naturally on the fourteenth day after the operation. On the twenty-first day the wound had granulated up to the surface and had almost healed. The boy was now allowed to pass his urine voluntarily, which he did readily and without pain. He was discharged on the twenty-fifth day after the operation.

Remarks by Mr. BILTON POLLARD.—In the two cases treated by lithotrity the calculi were small. That this was the case was easily ascertained by the combined rectal and supra-pubic examination of the bladder. The urethra of a child aged two years and five months readily admitted a No. 5 lithotrite and a No. 6 evacuating catheter, whilst that of a child aged three years as readily admitted instruments three sizes larger. The stone in the first of the two cases treated by supra-pubic lithotomy was a large one (562 grains), and as the bladder contracted so closely on to the stone, there was some difficulty in extracting it. The bladder, the recti muscles, and the skin were sutured, and the boy was allowed to pass his urine by his own efforts. The case, so far as the operation was concerned, was altogether successful. The bladder and the superficial wound healed quickly, without any leakage of urine. In the last case the stone was dumb-bell shaped. One end was impacted in the prostatic portion of the urethra, and the other projected into the bladder. The stone was disengaged from the urethra, and extracted through the supra-pubic opening. The bladder was sutured with carbolised catgut, and the skin wound was closed except at the lower end, where a small tube was inserted. As the boy had not voided urine for five hours after the operation a catheter was passed. He was then, owing to a misunderstanding, allowed to go for twelve hours without emptying his bladder. During this time one of the sutures in the bladder gave way, and a free escape of urine from the wound took place. The catheter was passed regularly afterwards, and though some leakage from the bladder occurred twice more, the wound healed rapidly without a bad symptom. Recovery was certainly hastened by suturing the wound in the bladder.

LEEDS GENERAL INFIRMARY.

A CASE OF RETROFLEXION OF THE UTERUS; HYSTEROPEXIA; REMARKS.

(Under the care of Mr. W. H. BROWN, Assistant Surgeon.)

THE treatment of obstinate retroflexion or of prolapse of the uterus is now no longer confined to the introduction of pessaries, plastic operations on the vagina or perineum, or to any of these in combination with local depletive measures where the uterus is of abnormal size. In cases of retroflexion Alexander's operation of shortening the round ligaments is one which, when the uterus has not been fixed by adhesions, has proved successful in many hands; if, however, the adhesions can be broken down by external manipulation of the uterus by the method of Schultze[1] or Ter-Grigoriantz,[2] it may then be employed with success. In the following case the fundus of the uterus was firmly fixed in its abnormal position, and the only way of effectually dealing with the adhesions was after abdominal section. When these have been separated the uterus may be fixed to the anterior abdominal wall by means of sutures passed in various ways. Kelly[3] passes a single silkworm gut suture through or around the round ligaments at their junction with the uterus on either side, and through the peritoneal coat of the bladder at the point on which the uterus naturally rests, and then ties them. When there have been adhesions he passes two or three sutures of silkworm gut or silver wire through each round ligament near its uterine end, and deeply into the abdominal wall just above the symphysis pubis on either side of the incision, and at a distance from it about equal to half the breadth of the uterus; when all are placed in position they are tied. Leopold[4] passes two sutures on each side through the edges of the abdominal incision and lightly through the uterus, one near the attachment of the round ligament, the other in front of the entrance of the Fallopian tube; the sutures are removed on the tenth day. He also freshens the opposed surfaces by scraping them lightly. Wylie[5] makes a fold with a loose ligature on each tube, and freshens the opposed surfaces by scraping them. Sänger[6] stitches the round ligaments at their uterine insertion to the anterior abdominal wall; he does not believe in the operation performed by Alexander. When a condition of retroflexion or prolapse is conjoined with disease of the appendages, a good result has followed the stitching of the stump or stumps to the abdominal wall external to the median incision, and of this modification we have published a very successful case by Dr. John Phillips.[7] Caneva[8] of Milan proposed to secure adhesion of the uterus to the anterior abdominal wall by holding the uterus in position by means of an intra-uterine sound. We need not refer to other methods, such as the vaginal suture of Schücking.[9] Terrier[10] performed an operation similar to that which we record, but for prolapse, and united the peritoneal covering of the uterus to the parietal peritoneum by four points of silk suture. Mundé and Wells give an excellent summary of the more recent treatment in flexions of the uterus.[11] For the notes of the following case we are indebted to Mr. Mitchell, house surgeon.

E. L——, aged forty-two, was sent to Mr. Brown by Dr. Henry White of Bradford, who had had her under his

observation for some time. There was a history of ten years' pelvic suffering. For the last two years she had been practically bedridden. There had been occasional menorrhagia, and this, together with constant pain, had produced a marked diminution in the patient's strength. She had worn many forms of uterine support, both intra-vaginal and intra-uterine, but each and all of these had been the cause of an increase of her suffering, and had in consequence to be removed within a day or two of their introduction.

Upon examination per vaginam marked retroflexion of the uterus was found, the fundus presenting at the vulva. Any attempt at reposition caused agonising pain. A sound could not be introduced. Bimanually Mr. Brown thought he detected a solid tumour occupying the hypogastrium, but was uncertain, as the rigidity of the muscles prevented anything like a thorough examination. The woman was in great misery, and willingly consented to submit to abdominal exploration; accordingly she was placed under ether, and Mr. Brown opened the abdomen in the middle line, adopting the usual precautions.

On introducing his fingers into the abdominal cavity the operator found that what had appeared to be a growth in the hypogastrium had been due to muscular tension. He further found the uterus in the position before described, and held down by very firm adhesions. These adhesions were broken down and the now movable uterus brought out of the pelvis. Both ovaries were natural. On the posterior surface of the uterus was a small fibroid tumour. A catheter was now passed into the bladder, and that viscus stretched by the instrument so that it was possible to ascertain approximately its upward limit. The fundus of the uterus could be brought easily in contact with the abdominal wall above this point. Mr. Brown now transfixed the uterus with a curved needle armed with silk, taking a good hold of its tissue, and bringing the ends of the suture through the muscular wall of the abdomen, tying and cutting off the ends short. The abdominal wound was closed in the ordinary way.

The after history of the case was uneventful, and the patient left the hospital five weeks after operation. She could then move about easily, and her pain had entirely disappeared. There was no complaint by her on her departure. An examination per vaginam made the day before she left showed the uterus to be slightly anteflexed, and much in the same position as that of a multipara.

Remarks by Mr. BROWN.—So far as I can gather, the procedure which I have above described has not often been resorted to in the treatment of obstinate retroflexion of uterus. Kœberlé, I believe, was the first to introduce a method very similar. In the face of the facts I have recorded it would seem to me that this operation, modified in detail to suit individual cases, might well be added to the list of remedies to be employed in dealing with intractable flexions of the uterus.

Medical Societies.

CLINICAL SOCIETY OF LONDON.

Cholecystotomy.

THE first ordinary meeting of this Society for the present session was held at 20, Hanover-square, on Oct. 25th, Mr. Christopher Heath, President, being in the chair.

The PRESIDENT, on taking the chair, addressed a few words of congratulation to the members on their assembling for the first time in their new home. He desired particularly to offer his thanks to the President of the Medical Society, who had kindly offered the Clinical Society temporary accommodation in case of need. He called attention to the feature introduced into the new volume of the Transactions; an appendix containing the after-history of many of the cases related in the earlier numbers; a great many most interesting facts had thus been brought to light, and the appendix formed a valuable addition to the volumes of Transactions.

Mr. MAYO ROBSON of Leeds then read a paper on fourteen cases of Cholecystotomy which he had performed; eleven being for gall-stones, one for empyema of the gall-bladder, and two for distended gall-bladder; due in the one case to cancer of the head of the pancreas; in the other to cancer of the bile-duct. All the patients operated on for gall-stones had recovered. Of the other cases, the patient suffering from empyema of the gall-bladder was operated on when apparently dying from acute peritonitis, but after the operation she made a good recovery except for a biliary fistula which was afterwards closed by cholecystenterostomy. The case of cancer of the pancreas had succumbed on the eight day to a constant oozing of blood from the interior of the gall-bladder, and from the suture punctures. It commenced on the day following the operation, and was apparently due to the altered condition of the blood, brought on by persistent jaundice of several months' duration. In the case of cancer of the bile duct, although there was intense jaundice, there was no subsequent bleeding, or other complication; this might possibly be due to the arrest of hæmorrhage at the time of operation by ligatures instead of by forcipressure. Of the cases operated on for gall-stones, six patients had sought advice in consequence of the presence of a tumour combined with the usual symptoms; in these cases, Mr. Robson pointed out that the operation was usually much simpler than in the other group, where no tumour could be felt, although in one, where an apparently solid tumour was exposed which was due to the matting of the viscera surrounding the gall-bladder, so that the mass appeared at first to be a malignant growth, it was found impossible to shut off the general peritoneal cavity by suturing the parietal peritoneum to the gall-bladder, as it was practically destroyed by suppuration; and drainage with sponge packing had to be resorted to, to prevent general peritoneal infection. Dr. Churton had pointed out to Mr. Robson that he had previously seen in the post-mortem room a similar condition of affairs, where suppuration of the gall-bladder had led to the formation of a tumour resembling a malignant growth, but where an exploring needle pushed through the overlapping edge of the liver had revealed the presence of pus. Of the cases, five in number, operated on, on the strength of symptoms alone, Mr. Robson remarked that he believed many such cases of frequently recurring biliary colic would in future be saved the intense suffering and the many dangers of their disease by timely operation. He pointed out that these operations were not always easy, as the gall-bladder was frequently very small, and could with difficulty be brought to the surface; in fact, in his fourteenth case the gall-bladder was shrunken to the size of the last joint of the thumb, and was lying very deeply under cover of the liver, so that when he had incised it and removed several gall-stones from the duct, the lower part of the opening could not be made to reach the parietal peritoneum, and a piece of omentum was brought up and sutured on the one hand to the gall-bladder, and on the other to the parietal peritoneum, thus shutting out the general peritoneal cavity. Mr. Robson thought that omentum grafting first proposed by Dr. Sena for enterorrhaphy, but he thought not hitherto performed to surmount a difficulty of the kind above related, would in future often be found very useful in abdominal surgery, and perhaps especially in such cases as he had mentioned. With regard to the danger of biliary fistula, Mr. Lawson Tait had remarked that "biliary fistula after cholecystotomy could only be permanent when the operation happened to be performed at a time when a gall-stone was impacted in the common duct;" the author of the paper said that he believed this to be true generally, as proved by Mr. Lawson Tait's cases, but in the only case of biliary fistula which had followed the operation in his own hands, the cause was other than gall-stones, as when he had performed the operation for the closure of the fistula, he had very carefully examined the whole length of the common duct, without finding an obstructing calculus. In conclusion, he remarked that he believed that with due care cholecystotomy, in the absence of malignant disease, was a procedure attended with comparatively little danger, and that the great relief which the operation conferred amply compensated for the attendant risks.

Dr. CHURTON said he had attended many of the earlier operations which had been related. He had noticed in the post-mortem room that the small gall-bladders could be most easily reached through the liver. Some of the calculi found were soft and easily broken, while others were as hard as quartz. The thickening sometimes found from surrounding inflammation looked remarkably like cancer. He was under the impression that the cancer of the gall-

Digitized by Google

bladder found in the ninth case related had been caused by the irritation of an impacted calculus which had afterwards become dislodged. The tables showed that a more than usual number of women were affected.

Dr. ANGEL MONEY related the case of a tailor, aged twenty-five, who came under his care with jaundice and a large tumour in the neighbourhood of the gall-bladder, which gave distinct grating on examination. It was operated on by Mr. Bilton Pollard, who first aspirated and then removed from the bladder a large number of stones; a biliary fistula remained.

Surgeon-Major BARKER recommended the administration of large doses of chloroform by mouth, which frequently produced excellent effects on gall-stones.

Mr. K. THORNTON said that the question of diagnosis was sometimes a difficult one. In a large majority of distended gall-bladders the diagnosis was simple, but if the swelling were very large, the diagnosis from tumour of the kidney had to be made. Cases with adhesions round the gall-bladder and suppuration were very difficult to make out; it was hard to decide whether they were malignant or simply inflammatory. The cure was very rapid in those cases with thick adhesions. In none of the cases in which he had operated had fistula resulted, nor had he met with a malignant case. With regard to the operation, if the gall-bladder were distended it was simple enough, but if the stone were impacted in the common duct he knew of no more difficult one in surgery. He had suggested breaking up the stone by needling and leaving it to pass down the duct, and some he had treated so had done remarkably well. In one case he slit the duct open, broke the stone up with his fingers, and then sewed up the opening. The enormous quantity of bile-stained mucus that poured away from these cases for some days after the operation was remarkable. He did not agree with Dr. Churton that those cases with a great quantity of mucus usually contained only a single stone, for in one case from which he removed 413 stones there was an enormous quantity of mucus. Again, in another case, where there was a large single stone, there was no suppuration and a very little fluid. The American treatment by oil had been much vaunted, but the bodies passed after taking this medicament were not gall-stones at all, but simply collections of oil and fæces. He had never attempted to open the gall-bladder into the bowel, and characterised such a proceeding as monstrous. Cases of cholecystectomy did wonderfully well, and did not seem to suffer at all from the loss of a gall-bladder.

Mr. CHARTERS SYMONDS thought there was a class of case in which no other treatment but cholecystenterostomy was available. He related a case which had been under Dr. Goodhart's care, in which the gall-bladder was distended with clear fluid. He opened it, but could get nothing into the common duct. The bile passed through the fistula in very great quantity; he therefore undertook a second operation, and joined the gall-bladder to the intestine. The latter kinked and sloughed, and the man died. At the autopsy there was found stenosis of the common duct at its duodenal orifice. He regretted he had not done the second operation before the gall-bladder had contracted down.

Mr. A. E. BARKER related a case in which a gall-stone was suspected to be impacted in the common duct; he therefore explored, and found a healthy gall-bladder, but no stone. There was a little hardness about the head of the pancreas and an adhesion between the transverse colon and the edge of the liver. He closed the wound, and the patient recovered, being much benefited by the operation. Other surgeons had had similar experiences.

Mr. BLACK detailed a case of jaundice which was suspected to be due to gallstone, but which turned out to be lead poisoning.

Mr. ROBSON, in reply, thought that in Mr. Barker's case relief might have resulted from breaking down the adhesions. He knew of two negative explorations which occurred in the practice of his colleagues, and both of which resulted in cure. A German surgeon had recorded a case of ruptured gall-bladder in which ten pints of bile had drained into the peritoneum without producing an untoward result, but still he thought it safer to close the opening into the peritoneum. He had had but one case of fistula, and in that less than two ounces of clear inodorous mucus were secreted in the twenty-four hours, and this possessed antiseptic qualities and gave rise to but little inconvenience. Cholecystectomy, though often a difficult operation, like adherent pyosalpinx, seemed by statistics to be quite as safe as cholecystotomy.

MEDICAL SOCIETY OF LONDON.

Glycosuria.

AN ordinary meeting of this Society was held on Oct. 28th, Dr. Theodore Williams, President, in the chair.

Dr. ORD read a paper on Some Points of Interest in regard to the Presence of Sugar in the Urine. He had published some time ago, in the St. Thomas's Hospital Reports, some notes on glycosuria in people past middle life, and he now added a few statements and remarks by way of supplement and illustration. The conditions which determined the presence of sugar in the urine in pathological quantity were :—1. Excessive afflux of arterial blood to the liver, and probably to other glycogenic organs. 2. Defective assimilation of glucose. 3. Defective formation of glycogen. 4. Instability of glycogen—i.e., the formation of glycogen which was too ready to change. 5. Excessive ingestion of glucose or glucose-yielding substances. Under the first head might be gathered several kinds of cause—e.g., (*a*) vaso-motor paralysis determined by disease, or injury of the medullary centre, or of the nerves connecting the centre with the arteries of the liver: (*b*) dilatation of the hepatic artery, not determined by disease of nerve centre or centres, but by irritation of the liver, or determined by reflex action at the instigation of other organs, such as the stomach or by general disorder of the circulation; functional, as a result of nerve strain or excitement, functional and probably also dyscratic as in gout; (*c*) possibly also compensatory arterial hyperæmia, balancing obstruction of the arterial circulation in other parts and systems of the body. Dr. Lauder Brunton, in his "Handbook for the Physiological Laboratory," gave an admirable summary of the various ways in which nerve sections and nerve irritations might produce glycosuria, and he stated that it was of great importance to note that section of the sympathetic cord or splanchnic nerves did not produce diabetes, although the vaso-motor nerves of the liver were thus divided, his explanation of this being that as the vaso-motor nerves of the intestines were divided at the same time, so much blood went to the intestinal vessels that the circulation in the liver was not increased. If this explanation were admitted, it seemed reasonable to argue that an undue contraction of arteries in other parts of the body than the liver might determine an excessive blood-pressure in the arteries of that organ, and so set up glycosuria, the liver itself not being necessarily at fault. His notes afforded several instances showing the influence of heredity in bringing about glycosuria, but it was of course evident that the existence of this affection in minor degrees had been often overlooked in the past, and that a better estimation of the transmission of the tendency would in the future be more possible under the steady maintenance of careful examination of the urine. As to the way in which the transmission was ordered, in one case it seemed to go with the gouty diathesis from the father's side; in others it was observed who were the subjects of nervous instability; in others, again, these conditions were absent, and tissue imperfections had to be invoked, the occurrence of glycosuria in very stout people being a noteworthy fact. He was inclined to regard both the accumulation of fat and the occurrence of glycosuria as marks of imperfect forms of nutrition. In many cases, in conjunction with obesity, the influence of persistent alcoholic excitement of the liver could not be overlooked, the irritation producing a reflex active hyperæmia and consequently glycosuria. For those victims of alcoholism who presented glycosuria, and who were emaciated, a different explanation must be sought. A considerable proportion of these cases had valvular disease of the heart, and irregularities of arterial tension might here have to be considered. It was not unfrequent to find people suffering with symptoms of contracting granular kidney to be also affected with glycosuria. Whether it was here due to a general defect of assimilative or constructive process or related with a very definite arterial tension was not easily to be decided. Again, he had observed the occurrence of glycosuria in two cases of Raynaud's disease, and in a third with disease of kidneys, sloughing ulcers, and syphilis. From cases he had since seen he concluded that glycosuria was often present in tertiary syphilis, and under conditions not involving irritation of the medulla. In these cases signs of hepatic disorder were always present, and he thought that hepatic irritation was mainly chargeable with the production of the glycosuria. But he dared not speak with

Digitized by Google

any tone of decision on this point, when he remembered the possibility that faulty tissue-building at large might have to be considered. Muscular and other tissues, as well as the liver, were the seats of formation of glycogen, and it appeared to him quite possible that a disturbance of nutrition in muscles, in spinal cord, and in liver might exist independently in each and give rise to glycosuria; while, on the other hand, a deep dystrophy might affect all at once. Several cases of angina pectoris in association with glycosuria had come under his knowledge, and he related one at length in which this conjunction existed. He thought it must be admitted that angina was no more an essential disease than glycosuria, and he recognised in it varieties of form and causation which ran in curiously parallel lines with those of glycosuria. Everyone recognised the typical form of angina wherein degeneration of the heart muscle played one part and arterial stress another; and everyone would also further admit that disorder of innervation played an important part in disturbing the balance between the heart and the arteries. Glycosuria also might be a mark of disordered innervation, but in a preponderance of cases presenting glycosuria together with symptoms of angina the evidence of primary neurotic disturbance had not been strong. The subject of the occurrence of sugar in the urine of women in whom lactation had been suppressed was then discussed. The chemical reactions obtained in several cases appeared to correspond exactly with those which would be yielded by glucose, but their rapid evanescence had so far stood in the way of the obtaining any sufficient quantity of urine to afford opportunity of a complete investigation. The indication was apparently that the stoppage of the secretion of milk had determined a backward flow into the vessels of lactose in a quantity so large as to be represented by the appearance of a considerable quantity of glucose in the urine. M. Germain Sée had shown that, while milk taken in large doses produced diuresis and a very marked glycosuria, large doses of lactose caused a remarkable polyuria, but no glycosuria; why this should be was not clear. Not many years ago, when albumen was found in a patient's urine, he was supposed to have Bright's disease; and so now, it was very often the practice to speak of the existence of a small quantity of sugar in the urine as justifying the use of the term diabetes. He thought that those who had studied the question most thoroughly would agree that this was a most unwise use of the term; unwise as bearing alike upon prognosis and treatment. If his views of the analysis of the causes of glycosuria were at all to be admitted, it followed that the treatment of a glycosuria which was subordinate must be involved in the treatment of the major part of the case. What he had put forward was rather analytical and suggestive than final or didactic, and he submitted for criticism, and proposed for investigation, certain associations of glycosuria which had presented themselves to him, and to which he had devoted a good deal of thought.

Dr. PAVY had found glycosuria frequently associated with obesity and with spareness, but he could not conclude that there was any absolute connexion between them; in stout people, however, the disease seemed to be more amenable to management. He recognised a connexion between glycosuria and enlargement of the liver; in many of the latter the disease was not of the ordinary form, for they possessed a certain amount of power to assimilate carbo-hydrates. A contracted granular kidney seemed to exert a restraining influence over the diabetic condition, and in cases where chronic interstitial nephritis developed in the course of a case of diabetes the same restrictions of diet were not necessary in order to keep the sugar under. He had observed that glycosuria was often accompanied by peripheral neuritis, especially after middle life; and in the gangrene of the toes, often associated with diabetic cases, there was an amount of pain out of proportion to the gangrenous condition; and, if glycosuria were really connected with nerve disease, it was not strange to find angina pectoris or exophthalmic goitre associated with it. He agreed with Dr. Ord that it was unwise to confine our attention too exclusively to the liver. It was merely a matter of limitation of the assimilative capacity, for even in healthy people that capacity was not unlimited. In some diseases of the liver very little of the secreting structure was left, and yet these patients did not get diabetes, and that was one reason why a broader view should be taken as to the causation of this affection.

Dr. RALFE also thought we should look beyond malassimilation by the liver. There were two great groups of cases presenting sugar in the urine: (1) Acute cases coming on with a threatening aspect, in which there was a great drainage of water and sugar from the system and early and rapid emaciation; (2) a class of cases coming on more insidiously, associated with gout, syphilis, heredity, or kidney mischief. It was of much slower duration, the patient was often stout, and the disease drifted on for years and years, and then was not, perhaps, of itself fatal. Dr. Purdy had shown him some tracings taken from cases of diabetes; there was marked tension of the vessels like that seen in renal disease, but there was no albumen and no casts, nor was there reason to suspect gout. A Carlsbad physician had asserted that in all cases of diabetes the left ventricle of the heart was hypertrophied, and the vessel walls were thickened; the arterial tension later gave way to degeneration. It had been pointed out that in cases where suppression of lactation had occurred crystals of lactose were found in the urine; it did not become converted into glucose.

Dr. SAVAGE spoke as to the relations of diabetes with insanity. They were both directly hereditary, and it was common in insane people to get a history of diabetes in the parents; it was nevertheless uncommon to meet with sugar in the actively insane; those cases in which he had found sugar were puerperal. In many patients insanity had been observed to alternate with glycosuria; when they recovered from an attack of insanity the sugar had reappeared in the urine.

Dr. S. WEST said that Dr. Pavy had used increased arterial tension to explain the favourable course diabetes ran when granular kidney developed, but in exophthalmic goitre the tension was far from increased. He asked if diabetes could be produced by errors of diet. He quoted the case of a girl who, as assistant in a grocer's shop, ate a very large quantity of sugar, and died of acute diabetes.

Dr. PAVY disclaimed any intention of asserting that increased arterial tension caused diabetes; he thought rather it was due to a vaso-motor paralysis, a dilatation of vessels.

Sir WILLIAM ROBERTS remarked on the extraordinary way diabetes complicated all sorts of morbid conditions. He thought that Dr. Pavy had touched nearer to the solution of the problem of diabetes than any physiologist now living. It was a disease most puzzling to study, and it had almost as many paradoxes as gout itself.

Dr. MITCHELL BRUCE referred to two classes of cases which had glycosuria in combination with gangrene: (1) stout middle-aged people whose toes became gangrenous, and on whom opium exerted a remarkable influence; and (2) patients with typical Raynaud's disease. He had seen a patient suffering from the latter affection in whom the disease was arrested by morphine, and he wondered whether in the liver in diabetes there might not be a condition of peripheral neuritis, for it certainly was not necessary that the disease of the nervous system should be central.

Dr. MAGUIRE said that though gout might be the connecting link between some cases of granular kidney and glycosuria, yet there was a connexion between diabetes and a certain degree of granular kidney in which no gouty element was present. When albuminuria occurred in diabetes it indicated a hardening of the kidney, and did not suggest a bad prognosis; on the contrary, it was extremely likely that the condition of the diabetic patient would improve. The kidney in these cases was not a typically contracted organ; it was dark red, the capsule was slightly adherent, the surface faintly granular, and the whole organ tougher.

Dr. WILLIAMS asked what proportion of cases showed the presence of carbuncle, and also in what number of cases phthisis was observed.

Dr. ORD, in reply, said he had not met at all frequently with either carbuncle or phthisis in glycosuria, but they were common in true diabetes. As to the connexion with obesity, he had seen a good many cases in which glycosuria and obesity existed alone, but in thin patients there was always some other causative condition present. In one of his cases the patient had marked signs of granular kidney with hard arteries and plenty of casts; the sugar was very small in quantity, and could not have produced the disease of the kidney. He did not know whether diabetes could be produced by errors of diet.

HARVEIAN SOCIETY.

Treatment of Pneumonia by the Ice-bag.

AT the meeting on Oct. 17th, Thomas Buzzard, M.D., F.R.C.P., President, in the chair, Dr. LEES read a paper on the Treatment of Pneumonia by the Ice-bag, which will be found elsewhere in our columns. The following discussion ensued :—

Dr. GOODHART had for eighteen months used no other application than the ice-bag in cases of acute pneumonia, and he gave an account of eighteen cases thus treated. A good result was obtained in eight cases, the temperature falling promptly, the pulse becoming decreased in frequency, and convalescence being rapidly established. In seven cases it was doubtful if the treatment had had any effect whatever; while in three cases symptoms of collapse were produced of a very temporary nature, for it subsided as soon as the ice-bags were removed. It was difficult to eliminate the question of the natural crisis of a pneumonia having coincided merely with the application of the ice, but it was also possible to underrate the value of any treatment because of the presence of pleurisy, which interfered with the beneficial results of the remedy. Dr. Goodhart, however, concluded that there was no danger in applying this treatment, such collapse as might occur being easily detected, and remedied by brandy and warmth to the feet, and by avoiding its use in patients under two years of age. He himself did not think that collapse was increased by the application of cold over the cardiac region. Moreover, he believed that warm applications were greatly overdone, and the ice treatment was a useful alternative.

Dr. STURGES had had but little experience of this mode of treatment. Nevertheless his conclusions were rather those of Dr. Goodhart than of Dr. Lees. All the cases Dr. Lees had described were of young persons, and the mortality in these was very small. In children especially it was difficult to decide between croupous and broncho pneumonia. Broncho pneumonia was dangerous, but croupous pneumonia in children was very rarely fatal. Three cases described by Dr. Lees were of broncho-pneumonia, and in these ice and bleeding had been very efficient in relieving the patient. These were the most important cases described, and Dr. Sturges thought the treatment most likely to be of use in broncho-pneumonia. In a case of lobar pneumonia in the Westminster Hospital under Dr. Donkin, the temperature rose to over 106°, and there was great prostration. The ice-pack was applied, and a recovery ensued. Dr. Sturges expressed the view that lobar pneumonia by its nature was such that it was impossible to say that any remedies were successful in curing the disease. The late Dr. Hughes Bennett had reported over a hundred cases of pneumonia, some in elderly people, with a mortality of only 5 per cent. Pneumonia and typhus in regard to the influence of remedies were much alike. The temperature, delirium, and headache were much relieved by drugs, and the patients made comfortable. In this way ice was certainly of use, as Dr. Sturges had himself observed; but he doubted if the evidence was yet sufficient for us to say that we arrested pneumonia. He doubted also if it was as a rule a great good to shorten the pneumonia. In the pneumonia of drunkards, however, the inflammation was very destructive; but this was a very different disease, and it was especially doubtful here if ice would be of any use. Dr. Coupland also had tried the ice in a few cases in young people; he was satisfied with the treatment on the whole, and had had no ill results. He also doubted if the treatment had shortened the cases, but it had certainly relieved the symptoms.

Dr. ANGEL MONEY made a sharp distinction between two forms of pneumonia. He would not, for instance, use the ice-bag in what he called epileptic pneumonia, styled by the French "herpetic pneumonia." Here the onset was so sudden, the course so definite, and the sudden termination so certain, that the disease resembled an epileptic fit. In other cases, however, the ice-bag was of great value, though he did not say it curtailed pneumonia. It relieved the patient, and it was safe in application.

Dr. SYDNEY PHILLIPS had used the ice-bag himself, and seen it used much by Dr. Wilson Fox. The temperature was undoubtedly lowered by the ice, but it might for this purpose be applied to any part of the body. An objection to the ice-bag was that on its removal the temperature again rose, and sometimes to a higher degree than before. This was the case with all antipyretics, and it was doubtful whether it was desirable to attempt a lowering of temperature by such means, unless it had attained a very high degree. The ice-bag scarcely shortened the disease.

Dr. TIRARD had tried the ice-bag treatment in the Evelina Hospital. Of six cases thus treated, three showed benefit to have been derived; in the other three alarming collapse resulted. In six other cases not treated by ice, and also without poultices, the course of the cases was always good. By the ice-bag comfort was increased, but the disease was not shortened.

Dr. LEES, in reply, said that he did not desire to overpraise the ice-bag. It was certainly difficult to arrive at the true conclusion as to a particular remedy. He thought it very desirable to cut short the disease, if possible. Lobar pneumonia in young children nearly always got well, but some cases did not get well, and the two cases of undoubted lobar pneumonia which he had mentioned were especially dangerous, and, he believed, would not have recovered if left to themselves. He hoped that, now it had been shown that no danger resulted from adopting this treatment, other observers would be induced to give it a trial and record their experience.

MIDLAND MEDICAL SOCIETY.

MR. ROSS JORDAN IN THE CHAIR.

WEDNESDAY, OCT. 16TH.

Muscular Atrophy in Locomotor Ataxia.—Dr. SUCKLING showed a man aged twenty-nine, suffering from locomotor ataxia with well-marked muscular atrophy, the case corresponding in all respects with those recently published by M. J. Déjerine in the *Revue de Médecine* for this year. The man, a stenographer, had lived in America for four years, and had suffered from ague. His present illness began in December, 1887, when he was seized with incessant vomiting. He used to suffer regularly every month from attacks of severe pain at the stomach, with incessant vomiting. These attacks lasted three or four days, and obliged him to go to bed. For a year they occurred every month and then became more frequent. The attacks occur now every few days and constitute his greatest trouble. In June, 1888, he noticed his hands were numb, the numbness beginning between the index and middle fingers of the right hand, and since then his hands and feet, forearms, and legs have wasted. He has twice lost the use of the left arm, the loss of power lasting several days and gradually disappearing. He has also had double vision and ptosis at times. His hair is grey, and he is emaciated and feeble. The Romberg symptom is present, but there is not much ataxia; the knee-jerk is lost on both sides, the other reflexes are normal. The pupils do not respond to light, but do to accommodation. He suffers from shooting pains in the legs and arms, and occasionally round the body. He has quite lost sexual power, and his bladder is weak. His hands are clawed and much wasted; the muscles of the feet are also much atrophied and the feet are clawed. No fibrillary contractions have been observed. He has had recently an attack of weakness of the left upper extremity, the grasp being very weak, and the wrist dropped. The fingers of both hands are numb, as is also the ulnar side of the left forearm. Sensation is markedly impaired in the little and ring fingers of both hands and along the inner side of each forearm, and also on the left side of the trunk from the second to the sixth intercostal spaces—all forms of sensation are impaired. The man has never had syphilis, has been steady, and there is no hereditary history. The reaction of degeneration is not present, but the reactions are short and sudden in the muscles of the left forearm. M. J. Déjerine has shown that the muscular atrophy in tabetics is due to peripheral neuritis, and Dr. Suckling considered that this case supported his views from a clinical aspect. Suspension was tried in this case, but could not be borne. Quinine was useless; morphia was the only drug that gave relief.

Hereditary Chorea (Huntington's Disease).—Dr. SUCKLING showed a man, aged thirty-nine, a machinist, suffering from this complaint. He had suffered from jerky movements of the hands and feet for three or four years. He states that he is always "on the jerk," and often stumbles. He is constantly "snuffing" from spasms of the diaphragm. The knee-jerk was normal; and there were no signs of disease beyond the move-

Digitized by Google

ments. He had had rheumatism slightly in one shoulder, but the heart was unaffected. He stated that the disease was in his family, and that his mother died at the age of fifty-six, after suffering for sixteen years from the complaint. She became quite helpless and unable to feed herself some years before she died from bronchitis. The patient's sister (aged thirty-eight) is also affected. She has suffered from the disease for five years, and cannot be trusted to wash dishes &c., as she always drops them. The patient's youngest daughter (aged twelve) is also affected with the disease. Dr. Suckling pointed out the distinctive features of hereditary from ordinary chorea. Hereditary chorea affects adults chiefly; it may come on in middle life, it is directly hereditary, not indirectly so, as in ordinary chorea. It cannot skip a generation; if a member of an affected family escapes, then the inheritance in his or her case ceases. At first the movements can be controlled by the will; but, as the disease progresses, become quite involuntary until the patient is unable to walk, becomes bedridden and demented. Ordinary chorea gets well. Hereditary chorea may remit or exacerbate, but never gets well. It probably is due to congenital faulty development of the nervous system, and in this respect is analogous to Friedreich's ataxia.

Amputation of Leg.—Mr. JORDAN LLOYD showed a leg that he had recently amputated for chronic ulceration. There was very great hypertrophy of the skin and subcutaneous tissues, together with some thickening of the bone.

Mr. MARSH read a paper on the Treatment of Malignant Disease of the Rectum, and showed a patient from whom he had excised the rectum, after having done a preliminary colotomy.

The following gentlemen have been elected office-bearers for the ensuing year.—President: Mr. Lawson Tait. Ex-President: Mr. Hugh Ker. Members of Council: Drs. Holmes Joy, A. Underhill, Simon, and Messrs. Bennett May, Jordan Lloyd, Messiter, Chavasse, Barling, Priestley Smith, A. Clay, Eales, and W. Thomas. Treasurer: Mr. Garner. Secretaries: Dr. Suckling and Mr. Haslam.

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY

THE opening meeting of this Society was held on Wednesday, October 16th, Mr. Joseph White, President, in the chair, when the inaugural address on the "Prophylaxis of Uric-acid Gravel" was delivered by Sir WILLIAM ROBERTS.

The lecturer detailed various experiments carried out by himself, with the object of discovering the conditions most favourable to the formation of uric-acid gravel, and showed that the most important factors were acidity of the urine, sparse urinary pigmentation, and to some extent diminution in quantity. He believed that the excessive formation of uric acid was of less importance than was usually considered. The treatment should be directed to correcting the above conditions. Large doses of bicarbonate of potash, the bicarbonate of soda, or the carbonate of lithia should be given. A "mid-sleep" dose was insisted on, as of much value. With regard to the dietetic treatment, he pointed out the common occurrence of stone in India, and amongst the children of the poor, in both of which cases cereal diet was largely consumed. Food of this nature should be sparingly taken by people having a tendency to the formation of gravel.

A vote of thanks to Sir William Roberts was proposed by Dr. Tate, seconded by Dr. Curgenven, and carried unanimously.

TESTIMONIAL TO MR. SIDNEY PLOWMAN, F.R.C.S. An event of much interest took place at St. Thomas's Hospital on Saturday, the 26th ult., when Mr. Sidney Plowman, who is leaving the hospital, having accepted the appointment of Professor of Pharmacology &c. to the University of Melbourne, was presented with the new edition of the "Encyclopædia Britannica" in an open case. Dr. Bristowe, who made the presentation on behalf of the subscribers, referred in most complimentary terms to the high position which Mr. Plowman had made for himself both as a lecturer and teacher in the medical school, and whilst congratulating Mr. Plowman on his appointment, regretted the loss which his departure would be to both hospital and friends.

Reviews and Notices of Books.

Gynæcological Electro-therapeutics. By HORATIO R. BIGELOW, M.D. London: H. K. Lewis. 1889.

THIS volume begins with an introduction by Dr. Apostoli, giving a cursory review of various kinds of electricity and their application to various diseases. The book deals with electrical laws, various kinds of electricity, batteries, tumours of the uterus and their treatment, diseases of the ovaries and tubes and peri-uterine inflammation, metritis and endo-metritis, disorders of menstruation, displacements of the uterus, and additional cases, with discussion.

The methods of electricity are fully explained, with many illustrations, but at the present date it is not too much to expect some proof of the effects of electricity on living tissues. While discussions on this question seem to occupy much time in societies, facts are conspicuous by their absence. Before statements as to the effects of electricity on the uterus, fibroids &c., can be properly discussed, we ought to be able to read some accounts of actual experiments on fibroid and other tumours on the external and accessible regions of the body. That so much clinical statement should at this time exist side by side with so little scientific research seems to us to be a reproach to all who claim to erect electro-therapeutics into a great curative system. As regards clinical results, opinions and experiences vary widely, as will be seen even in the appendix to this work. According to these various views, electricity is a panacea, untrustworthy, or useless.

Among the supporters of the treatment in London are mentioned Drs. Steavenson and Duncan. The apposition of these names would seem to imply that Dr. Matthews Duncan (obstetric physician to St. Bartholomew's Hospital, of which Dr. Steavenson is electrician) was the person referred to. We cannot find that Dr. Matthews Duncan has anywhere expressed his approval, although most of Dr. Steavenson's cases came out of his department. Indeed, he did not speak in the discussion on electrolysis at the Obstetrical Society (Obst. Trans. for 1888). In the twenty-fourth volume of the St. Bartholomew's Hospital Reports, 1888, pp. 89–130, will be found a paper by Dr. Steavenson on thirty cases of uterine fibroids treated by electricity. His results are thus summed up, p. 129:—

"In eight cases the result may be described as very good, the patients having greatly improved and the tumours diminished in size. Fifteen others may be said to have improved, the symptoms being relieved; in one of these cases the tumour was larger at the end of a year, but the distressing and exhausting symptom of loss of blood, for which treatment was primarily sought, was relieved and has not recurred. Two cases of the fifteen were improved at the time they left the hospital, but we have not since heard of them. In one case the tumour was extruded from the os and removed by the écraseur; in one case the occurrence of pneumonia cut short the treatment; in four others no improvement took place; two improved while under treatment, but relapsed; one case ended fatally by ulceration into a large vessel.....The results of the cases reported are not as brilliant as could be wished, and the treatment is not altogether free from danger, as shown by the fatal case; but, compared with other methods, it is probably the best short of actual removal by operation. *Whether the advantage, which is small, is worth the extra trouble and time involved it is difficult to say;* this point can possibly only be decided by reference to the circumstances connected with each case. It would seem that Dr. Apostoli has not found it so uniformly successful as at first he believed, for he has recently advocated the treatment of uterine fibroids by the interrupted current."

When a man possessed of the technical knowledge of electricity of Dr. Steavenson has appropriate cases selected for him by a man of the calibre of Dr. Matthews Duncan, and tells us that he is doubtful whether the game is worth

Digitized by Google

the candle, we really think that the most serious indictment yet produced has been brought forward against the treatment.

Finally, we refer our readers, especially electricians, to the summing up of the President of the Obstetrical Society (Dr. John Williams) on the occasion of the debate on electrolysis.[1] There will be found an analysis of the principal utterances of Dr. Apostoli and his followers. He refers to the fact that in 1881 Dr. Apostoli advised treating the uterus during the lying-in period by faradisation with a view to prevent subinvolution, metritis, and other evils. This proposal he left to the judgment of each Fellow of the Society. He points out, as we have been obliged to do, that the literature consists of descriptions of instruments and of sweeping assertions. The work of Dr. Carlet (Dr. Apostoli's pupil) contains the following statement: "It is certain that, in practice, small, interstitial fibroid tumours, which require for their diagnosis great skill in digital examination and in the use of the sound, are often regarded as chronic metritis, *engorgement of the ileum, ulceration of the neck*, anteversion, anteflexion, and especially retroflexion and retroversion." It will be observed, therefore, that, in the case of Dr. Apostoli's series, we have not the guarantee of experience in diagnosis presented by that of Dr. Steavenson, which had mostly passed through the hands of Dr. Matthews Duncan. Hence, perhaps, the difference. Dr. Williams analyses Dr. Apostoli's cases in Dr. Carlet's book, and shows that the accuracy of diagnosis is very debateable, and the results do not compare favourably with those of the older methods. We are sorry that Dr. Bigelow makes no allusion in his book to either of these important publications.

A Handbook of Surgical Pathology, for the use of Students in the Museum of St. Bartholomew's Hospital. Second Edition. By W. J. WALSHAM, M.B., F.R.C.S., assisted by D'ARCY POWER, M.A., M.B., F.R.C.S. London: Baillière, Tindall, and Cox. 1890.

WE congratulate Mr. Walsham upon the appearance of a second edition of this work, it being eleven years since the production of the first, which has long been out of print. Since that time a renumbering of the whole of the specimens in the museum has of itself, even if no other reason existed, rendered necessary a revision of the work. In general plan and arrangement this handbook follows closely the original lines, it being really an amplification of the catalogue of St. Bartholomew's Museum. Two new points have been introduced: descriptions of many pathological conditions have been given which do not find illustration in the museum; this is a wise innovation, for it not only makes the volume more useful as a text-book to the St. Bartholomew's student, but it renders it more valuable to the general reader who has no opportunity of access to the specimens described. Another feature is the copious reference to the casts, drawings, and photographs, in which the museum is fortunately rich, and which are too often neglected by the student if his attention be not specially directed to them. Mr. Walsham has been fortunate in securing the collaboration of Mr. D'Arcy Power, the late curator, whose especial knowledge of the recent additions to the museum must have been invaluable in completing the revision of the work. The opening remarks with which the various sections commence have been extended and in many instances rewritten, and the whole have been brought well up to date. They still remain for the most part brief, simple, and clear; and, as for instance in the descriptions of tubercular disease of bones and joints, serve as embodiments of the most modern pathological teaching. We can confidently recommend the volume, which is handsomely got-up, not only to the students for whom it was originally intended, but also to the general surgical reader.

[1] Obst. Trans., vol. xxx. for 1888, pp. 285-8.

OUR LIBRARY TABLE.

Clinical Lectures on Diseases of the Nervous System. By Prof. J. M. CHARCOT. Vol. III. Translated by THOMAS SAVILL, M.D. Lond. London: The New Sydenham Society. 1889.—The subjects dealt with in this third volume of Professor Charcot's lectures, which the New Sydenham Society has produced, concern mainly functional affections of the nervous system. Hysteria, in various phases of its remarkable developments, and particularly the rarer forms of hysteria in the male, is, indeed, the main topic, to which many lectures are devoted. Needless to say the same vivid word-pictures and clear exposition so characteristic of all Professor Charcot's teachings find ample scope in dealing with such subjects. There are also in this volume lectures on Muscular Atrophy, Word-blindness, Tremors, and Choreiform Movements, the whole making a most interesting and attractive series, and fully maintaining the reputation of their author. As we have had occasion to notice these lectures in their original form, it is unnecessary to do more now than commend them to our readers, who will find in Dr. Savill's translation a faithful reproduction of Professor Charcot's text, and who cannot fail to be instructed by their perusal.

Die Geschichte der Tuberkulose. Von Dr. AUGUST PREDOHL. Hamburg und Leipzig: Leopold Voss. 1888.—There is no more fascinating subject in the history of medicine than the record of the gradual development of truer conceptions of the nature of tubercular disease. We see in it the evolution of all pathological doctrines, from that of gross morbid anatomy, when "tubercle" was used in its strict sense to denote every nodule or projection within an organ (e.g., cirrhosis of liver), to a special neoplasm, produced by a specific excitant and undergoing definite changes. Slowly, and often with the necessity of retracing their steps to previously attained points, have observers reached their present conceptions of the disease. Dr. Predohl deserves the thanks of all interested in pathological science for having collated almost every opinion on the subject, from the days of Morton to those of Koch; and for having presented the views of the large army of observers in a coherent and singularly lucid manner. His book should prove of service not only to the student of the history of medicine, but to the working pathologist, who will find in its pages many facts with which he would do well to familiarise himself. The subject is dealt with in three sections—viz.: (1) The Period before Villemin; (2) The Period of Experimental Research commencing with Villemin; (3) Tuberculosis, a parasitic infective disease.

Observations on some Rare Diseases of the Skin. By J. F. PAYNE, M.D. London: Smith, Elder, and Co.—Dr. Payne's *brochure* of fifty pages is a reprint, with some additions and the original illustrations, of rare cases, chiefly from the Pathological Transactions. They are: 1. Granuloma Fungoides. 2. Erythrasma. 3. A Nodose Condition of the Hair. 4. Pruritus Hyemalis. The first is the one of most importance, and the author gives a good *résumé* of our knowledge, to which he has himself contributed, of this formidable and interesting disease; but it seems a pity to try to replace Alibert's original name of "mycosis fungoïde" by a new name of German origin, which does not express any real addition to our knowledge of the pathology of the disease. Dermatologists will be glad to possess this record of interesting cases without having to hunt them up in the Pathological Transactions.

The Journal of Anatomy and Physiology.—Edited by Professors HUMPHRY, TURNER, and M'KENDRICK. Vol. xxiv. Part I. October, 1889. Williams and Norgate.—The contents of this part are:—1. The Proamnion and Amnion in the Chick, by Dr. Shore and J. W. Pickering, of St. Bartholomew's Hospital. 2. Variation in the Nerve Supply of the first Lumbrical Muscle in the Hand, by J. T. Wilson.

Digitized by Google

In two instances the muscle was supplied by the median and by the ulnar. 3. Function of the Prostate Gland in Man and Animals, by Joseph Griffiths. 4. The Vertebral Column of a young Gorilla, by Johnson Symington. 5. Innervation of the Axillary Muscles in Man, by J. T. Wilson. 6. Significance of Third Trochanter and other Bony Prominences in Man, by Thomas Dwight. 7. Vascular Anomalies observed in Session 1888-89, by Francis Shepherd. 8. The Flexors of the Digits of the Hand, by Bertram Windle. 9. The Organs of Taste in Belideus Ariel, by Fred. Tuckerman. 10. Contributions to Osteology of Arctic and Subarctic Water-birds, by R. W. Schufeldt. 11. Proportion of Bone and Cartilage in Lumbar Segment of Vertebral Column in Man and Apes, by Professor Cunningham. 12. By the same author, the occasional Eighth True Rib, and its relation to Right-handedness. 13. The Organs of Taste in Man, by F. Tuckerman. 14. Abnormal Vascular Supply to Liver, by Humphry Rolleston. 15. Proceedings of the Anatomical Society of Great Britain.

Fièvre des Foins, Pathogénie et Traitement. Par le Dr. MARCEL NATIER. Paris: O. Doin. 1889.—This *brochure* aims at being a review of the main theories of the origin of that troublesome affection hay-fever, which, the author remarks, appears to be far more common in America and England than elsewhere, and of the treatment based on these views. It may suffice to say that, after discussing the theory of the agency of pollen, originated by Elliotson and so ably supported by Blackley, the "arthritic" theory propounded by Guéneau de Mussy, and the "microbic" theory suggested by Helmholtz, he himself declares that the "nasal" theory originated by Daly, the serious acceptance of which dates only from 1884, when Hack published his work, best accords with the phenomena of the disease. This view accounts for the periodical recurrence with the summer season, in a special vaso-motor neurosis, whereby the erectile tissue of the nose is liable to excessive hyperæmia on comparatively slight causes of mechanical or chemical irritation. The "pollen theory" is quite hypothetical, but it is obviously possible to ally it to the special susceptibility of which the author speaks, which may be the root of the evil, and which apparently may lead to its radical cure by galvanic cauterisation of the nasal membrane.

The Quarterly Journal of Microscopical Science. No. cxviii., July, 1889. Edited by Professors RAY LANKESTER, KLEIN, and ADAM SEDGWICK.—This part contains the following Memoirs:—1. A Comparative Study of Striated Muscle, by Wm. A. Haswell, Sydney. 2. Contributions to Animal Chromatology, by C. A. MacMunn. 3. On Some Points in the Anatomy of Polyxenus Lagurus, by F. G. Heathcote. 4. A Remarkable Crustacean Parasite and its bearing on the Phylogeny of the Entomostraca, by Herbert Fowler. 5. Notes on the Anatomy of Scorpions, by Muliyil Narayanan. 6. The Anatomy of Phoronis Australis, by William B. Benham. 7. Karyokinesis and its Relation to the Process of Fertilisation, by W. Waldeyer. Eleven plates illustrate the memoirs.

The American Journal of the Medical Sciences. Published monthly. Edited by T. MINIS HAYS, A.M., M.D. Philadelphia: Lea Brothers & Co. August, 1889.—The excellence of this well-known journal has in no way suffered from its more frequent publication, and the number before us fully maintains its high reputation. Dr. Gairdner of Glasgow is the sole British contributor, with an article on a case of Anomalous Cardiac Murmur concurring with Fatal Cerebral Disease.

Zeitschrift für Biologie. Band xxvi., Hefte 2 und 3. Williams and Norgate. 1889.—This number contains the following articles:—1. On the Influence of Distension of the Peritoneal Cavity with Fluid on the Circulation and Respiration, by Dr. G. Heinricius of Helsingfors. 2. On the Causes of the First Inspiration, by Dr. G. Heinricius. 3. On the Importance of the Pulmonary Vagi in the New-born Child, by Dr. G. Heinricius. 4. On Secondary Muscular Excitation, by W. Kühne. 5. On the Nutritive Value of Beans in the Intestinal Canal of Man, by Dr. Wilhelm Pravsnitz. 6. On the Reduction of Hæmoglobin in the Heart, by Sophie Handler. 7. The Importance of the Mesocephalon for Respiration.

Analytical Records.

LIQ. EUONYMIN ET PEPSIN CO. (OPPENHEIMER'S).

(OPPENHEIMER BROS. AND CO., SUN-STREET, FINSBURY-SQUARE, LONDON.)

A DARK-BROWN, clear fluid, acid to test paper and bitter in taste. Analysis gave distinct proof of the presence of euonymin, and the activity of the pepsin was ascertained by its effect on white of egg. The preparation is evidently to be well trusted as a hepatic stimulant.

EUONYMIN COCOA, SPECIALLY PREPARED FOR DYSPEPTICS.

(OPPENHEIMER BROS. AND CO., SUN-STREET, FINSBURY-SQUARE.)

This, like the last, is a good preparation. The cocoa is of superior quality, and the euonymin, although perceptible, does not interfere materially with the cocoa flavour. Many persons who cannot digest cocoa will find this beneficial.

CREAM OF MALT WITH TEREBENE.

(OPPENHEIMER BROS. AND CO.)

Terebene is easily found in this compound, which, indeed, smells and tastes strongly of it. The malt extract used in the manufacture is excellent, for it converts starch very readily.

BEEF OATMEAL.

(H. AND T. KIRBY AND CO., LIMITED, NEWMAN-STREET, OXFORD-STREET.)

This beef oatmeal is prepared by Mr. Kirby's patent process for the manufacture of "Nutrimentin," by which fresh meat is condensed and preserved in an uncooked condition. To the eye and under the microscope this preparation appears like ordinary oatmeal, but the smell and flavour show the presence of some strong beef extract. When prepared with hot water as directed a most nutritious and palatable food is obtained. We think that beef oatmeal will be both useful and popular.

GERM BREAD AND BISCUITS.

(WATT AND SONS CLEDHOV-TERRACE, SOUTH KENSINGTON.)

Germ flour is said to consist of wheat germ specially treated and mixed with a certain proportion of fine roller-milled flour. It is well known that the germ is a peculiarly nutritious portion of the grain, and its successful use in bread and biscuit making is therefore satisfactory. The bread and biscuits submitted to us were excellent in appearance and flavour, and a microscopic examination showed freedom from irritating bran and from foreign admixture. This new food-preparation deserves commendation.

THE DENTAL ASSOCIATION.—The Midland Counties Branch of the British Dental Association held a meeting at Halifax last week, there being a good attendance. The proceedings were of an interesting nature, papers being read on Unregistered Practitioners and on Pulpless Teeth, whilst an apparatus was exhibited for the administration of nitrous oxide and oxygen for dental operations, some of the gentlemen in the room being experimented upon. A naso-pharyngeal apparatus for administering chloroform was also shown and its working explained, as was also an oxy-hydrogen apparatus for working by night or in dark weather.

THE LANCET.

LONDON: SATURDAY, NOVEMBER 2, 1889.

THE first report of the Royal Commission on Vaccination, just issued, commences with a statement of the order in which the evidence on the several subjects will be received. These subjects are as follows:—1. The historical and statistical case in favour of vaccination. 2. The arrangements made for vaccination under the existing law, and the mode in which the law is administered. 3. The case against vaccination, and especially against its continuing to be made compulsory. 4. The reply to these objections. 5. Any substitutes that can be suggested in place of vaccination for the purpose of preventing the spread of small-pox. 6. Any improvements that can be suggested in the present law or its administration for the purpose of removing objections to vaccination or making it more effective.

The volume now before us deals solely with the first-named subject, and hence it necessarily takes up one side of the question only. So far, four witnesses only have been heard, and it is evident from some of the questions put to them, and their replies, that they are not the only ones who will tender evidence under the first heading. It may therefore be assumed that a lengthened inquiry is in prospect, and that for this reason it has been thought desirable to issue the report in separate portions at different intervals, a plan which will at least have the advantage of enabling all who are interested in the subject to read the whole body of the evidence at their leisure.

Sir JOHN SIMON was appropriately called as the first witness, and his evidence was mainly historical in its character. Thus, he gave some history of vaccination from the days when it was first discovered by JENNER, but the greater part of his evidence was taken up in maintaining the principles laid down in his celebrated paper on the History and Practice of Vaccination, which he submitted to the General Board of Health in 1857, and which was at that time laid before Parliament. That paper has long been out of print, but as it is now embodied in the Appendix to this first report, it will once again be available for general use and reference. But whilst generally maintaining the attitude which he took in 1857, Sir JOHN SIMON wished it to be clearly understood that a further thirty years' experience of a subject which is hardly a century old had led him to modify his views on some points of detail; and in this connexion he especially instanced the duration of vaccination as a preventive of small-pox. JENNER vaccinated a large number of adults, and they appeared to have acquired a life-long protection; but as vaccination is more and more performed during the early years of life, so means have been afforded for ascertaining that the duration of the protection is limited; and whilst Sir JOHN SIMON still maintains that, in nearly all instances, the protection given by vaccination is never altogether effaced, yet he finds that the repetition of the operation is needed at an earlier date—namely, at about ten or twelve years of age—than he formerly thought necessary, if protection in the face of an epidemic is to be maintained. His cross-examination hardly dealt with the main features of his evidence. Some of it related to lay questions on obscure points of physiology, which even he did not feel able to answer straight off; other questions put to him had to do with the origin of vaccine lymph, and it was elicited from him that, as far as his knowledge went, he believed JENNER was right when he gave the name "variola vaccinæ" to the disease, and that it was really small-pox grafted on the cow. Some further questions were put to him, apparently to show that since "fever" and small-pox had, at least in London, diminished somewhat simultaneously, therefore the decrease in both diseases had been due to one and the same cause; but, even apart from the fact that some of the statistics in question as to "fever" were so far useless as to include such a disease as plague, the witness strongly maintained, as the result of his experience, that there was not the least reason for believing that there was any such connexion as had been suggested between the two diseases. And, lastly, being pressed by Mr. PICTON as to whether nurses in prevaccination days contracted small-pox to the same extent as those in attendance on that disease, and who have not been recently vaccinated, are now alleged to do, Sir JOHN SIMON reminded his questioner of the fact that in the earlier period referred to a very large proportion of adults had, before they became nurses, already suffered from small-pox, and therefore stood on the same footing as small-pox patients who elect to remain as small-pox nurses in hospitals in the present day; adding, "Let your unvaccinated, if they would like to make the experiment for the public service, try how *they* would fare if they exposed themselves to the same test."

Dr. WILLIAM OGLE, of the General Register Office, was the next witness, and he naturally dealt with the subject essentially from a statistical point of view. Taking the forty-six years since the registration of causes of death was established, and dividing it into two equal periods each of twenty-three years, he pointed out that whereas in the first period the small-pox death-rate was only twice under 100 per 1,000,000, it was so twelve times in the second period; and whereas in the first period the rate was only on five occasions under 150, it was so nineteen times in the second period. He then referred to the division which the Registrar-General made in one of his annual reports, showing that from 1838 to 1853, when vaccination was purely optional, the small-pox death-rate was 408 per 1,000,000; that from 1854 to 1871, when it was nominally compulsory, but when it was not obligatory to appoint officers to enforce compliance with the law, the rate fell to 223 per 1,000,000; and that from 1872 to 1887, a period in which the Vaccination Acts have been more efficiently enforced by properly appointed officers, the rate had fallen to 114 per 1,000,000, the decline in the whole period being about 72 per cent. A good deal of cross-examination was directed to the question why the third period was not made to commence with the year 1867, when the principal Vaccination Act was passed; and whilst Dr. OGLE admitted that the rates would naturally vary according as the heavy small-pox mortality of 1871 was placed in one or the other group, he yet maintained

Digitized by Google

that whilst the Act of 1867 was largely a complete Act on paper, he had decided, as the result of great pains taken to ascertain where the division of the periods ought properly to be made, that since before the vaccination officers were appointed under the Act of 1871 there was no such efficient carrying out of the Acts as ensued after these officers were appointed, he had rightly made his third period to commence at 1872. But at a later stage of his examination he varied the arrangement of the periods so as to change the position of 1871 with its epidemic, the result being that for 1838–39, when vaccination was not only voluntary but not even gratuitous, the small-pox death-rate was 827 per 1,000,000; that in 1840–53, when vaccination, though still voluntary, was made gratuitous, the rate fell to 336; that in 1854–67, when vaccination was nominally obligatory but not generally enforced, the rate fell further to 188; and that from 1868 onwards, including a long period in which officers have been appointed to enforce the Acts, the rate has still further fallen to 155.

The question of the age-incidence of small-pox mortality was next entered into at length, and it was explained that whereas small-pox has enormously diminished under five years of age, during 1847–1887, the period controlled by the vaccination laws, namely, from 1617 to 114 per 1,000,000, the diminution at from five to ten years has been less marked—namely, from 337 to 120 per 1,000,000; that from ten to fifteen years has been still less marked—namely, from 94 to 69 per 1,000,000; and that at higher ages a small but somewhat steady increase in the mortality has taken place. This Dr. OGLE attributed to the fact that whereas formerly many persons in adult life were protected against small-pox by an attack in infancy of that disease, they now only possessed the more waning protection of an infantile vaccination, "consequently the death-rates are increased during the more advanced ages because protection by vaccination has taken the place of protection by small-pox." As to this, Dr. OGLE was a good deal questioned with a view of ascertaining whether in any other disease, whilst there had been an enormous diminution in mortality at all ages, anything corresponding to small-pox which indicated a possible gradual extinction under five years of age with an increase at later years of life could be found. Dr. OGLE knew of no disease apart from small-pox which had behaved thus; and he could only interpret its special behaviour at different ages to the great protection of a recent vaccination and to its subsequent waning influence. As to "typhus," which in some way resembled small-pox as regards its diffusion, he explained that the seeming analogy was altogether misleading, since "typhus" in children formerly meant almost anything except real typhus, and that its omission from the death registers as a cause of infant death was essentially a matter of improved diagnosis and nomenclature. This led up to the question of the influence of sanitation as a preventive of small-pox, and Dr. OGLE expressed the conviction that, unless vaccination be included in the term, sanitation could not be regarded as having, to any material extent, diminished small-pox mortality. As bearing on this point, he regarded measles, scarlet fever, diphtheria, and whooping-cough, as fit to be compared with small-pox, and he showed that whereas the percentage of the deaths from small-pox under one year which had occurred in the last nine months of the year (i.e., after a vaccination at three months) had fallen from 63 to 50, as vaccination had been more and more enforced, the rate which corresponded with that 50 per cent. was, for measles 97 per cent., for scarlet fever 95 per cent., for diphtheria 89 per cent., and for whooping-cough 82 per cent.; and he urged that "the last nine months of the first year of life are for some reason or other protected against small-pox to a greater extent than they are protected against measles, scarlet fever, diphtheria, or whooping-cough"; vaccination, as applied to small-pox, alone explaining the difference. Some very useful and instructive tables relating to the matters dealt with in his evidence are contained in the Appendix to Dr. OGLE'S statement.

The remainder of the report we shall deal with in another article.

THE Archbishop of Canterbury has done well to devote his chief attention in his recent series of charges to the consideration of the Church's duty in respect of the two great national sins, intemperance and impurity. We have seen with satisfaction that the Nonconformist branches of the Church have been doing the same. The Church never appears to greater advantage than when helping men and women in the struggle with besetting sins; although sometimes it spends itself in petty questions which men feel to have no relation to their present life or any other. It is amazing how much swing such sins have in a Christian country, and even in its most religious parts. Nobody will doubt the religiousness of Scotland. No country has made greater sacrifices for her religion; no Church has had greater ministers than the Church of Scotland has had in such men as CHALMERS, MACLEOD, CAIRNS; but the reign of whisky is still unbroken, as it is in the equally religious country of Ireland. The Archbishop says that the evil of impurity is too strong for science, and quotes the grave and almost despairing words of the President of the British Medical Association as to the plague spot that "saps the health of millions." These evils are so dominant as to make both divines and men of science humble. Neither those who are supposed to be the ministers of the soul nor those whose special care is the body can afford to reproach each other. We, as medical men, certainly have tremendous responsibilities in regard to the prevalence of both sins. We see every day the consequences of them; often we are consulted about them by those who are in a state to receive not only medical but moral and friendly advice, and woe betide the physician or the surgeon who fails in his duty at such supreme moments of opportunity. The medical man who minifies vice in a patient, or who seems to sanction it, prostitutes his office and misleads his patient. He is like a pilot who takes his hapless ship into a tempestuous sea when he might have chosen still waters. We have lately quoted the opinions of Sir JAMES PAGET and Dr. GOWERS as to the safety of chastity and the physician's duty in regard to all breaches of it, actual or proposed. Their deliverances are practically unchallenged. If there are other and opposing voices in the profession they are ashamed to speak out. From the mere physical standpoint unchastity is fatal. We speak of its tendency, not of individual cases. If anyone doubts this let him read the account given in our

Digitized by Google

Paris correspondent's letters of the inheritance of syphilis, in THE LANCET of July 20th and Aug. 3rd and 17th. The authority is no less a one than Professor FOURNIER, who has not drifted into the fashion of speaking lightly of syphilis and its consequences as if it were a declining evil. It is to him "a veritable social calamity," "a factor in depopulation," "it has an enormous mortality following in its train," "it is a disease which affects the whole being, which by the general reaction it exercises on the organism, is capable of exciting, side by side with the symptoms or manifestations proper, others of another order, no longer syphilitic in the ordinary sense, although indirectly derived from syphilis, and which he proposes to term *parasyphilitic*." These are the words not of an English physician, who may be supposed to have puritanical prejudices, but of a French syphilographer who looks on social questions and on this great social plague with an experience probably not exceeded. Evidently in his case familiarity has bred no contempt of a disease which every man who abandons the lines of morality should be prepared to accept for himself and for his posterity. Neither must it be supposed that coarse or subtle physical disease is the only evil and retribution of unchastity. It is a misdirection altogether. It is giving up the mastery and regulation of the system, on which not health alone, but conduct and character, all depend. Admitted that the passion in question is an imperious one, it is still meant to be subordinate to reason, circumstance, and religion. We are not beasts, but social and rational beings. The sexual passion in man cannot be wantonly exercised without disturbing his whole nature and subordinating that which should be uppermost. There is much the same difference between the capricious, sensual, impulsive use of this function and its regulated recognition in marriage as there is between St. Vitus's dance and regular muscular exercise, and the medical man who advises or connives at the former must have an uneasy sense of responsibility if his patient becomes irregular in other respects. But we must insist that if any such medical men exist, they do not represent either the science or the ethics of medicine.

The vice of intemperance was discussed with great care by the Archbishop. He spoke with much caution on legislative enactments for its abatement. One of the best things the Archbishop said was that to make a political contest out of such a question would be bad both for politics and morals. It is one of the evils of our present constitutional system that such an urgent question cannot be discussed apart from political grounds and tactics. He quoted the saying of the Lord Chief Justice, that scarcely a crime came before him which was not directly or indirectly caused by strong drink. The Primate saw nothing inconsistent with this in admitting that the criminal had rarely had a good start; he inherits too often a vicious constitution, and is born into a criminal atmosphere. Apart from the intemperance that leads to crime, there is the great mass of intemperance that leads to poverty, and a less degree still that yet leads to various forms of ill-health. The responsibility of the medical profession is perhaps greater here than in the case of the first vice we have noticed. Undoubtedly some medical men too lightly prescribe alcoholic stimulants for their patients. And it is equally certain that the prescription is used as an excuse for taking the stimulants long after the necessity for them has passed away, and when all other parts of the physician's prescription have ceased to be remembered or regarded. Further, it is only fair to medical men to say that the most distinguished members of the profession have given a new meaning to intemperance, and have shown that quantities which a few years ago were considered moderate are fruitful sources of ailment and even of disease, and that the leaders of the profession at least are conspicuous for their moderation. Still, we cannot fail to see that by our prescriptions and by our example we may mightily help or hinder improvement in the national habits in this respect. We are probably the most gouty nation under the sun, and for nineteen centuries at least we have been drinking freely. It is time to reconsider our habits. A little more sobriety will certainly not be inconsistent with our national virtues, and it will immensely reduce poverty, misery, and disease. The clergy are siding most creditably with the promoters of temperance. So should medical men, not intemperately, but by caution in prescription, the condemnation of all casual drinking without food, and by the utmost care in personal habits.

WHENEVER any radical change of treatment of any common disease is recommended, it has to encounter numerous objections, not only before it is generally adopted, but even before it is fairly tested. A new treatment always runs the risk of being lightly turned aside; perhaps, in some cases, from the distrust aroused by the energy with which it is advocated. Accounts of new medicinal remedies in particular are ordinarily received with great reserve. The chemical composition and the physiological action are closely interrogated before statements of clinical results are allowed to pass as scientific facts. The sources of fallacy are so numerous that scepticism ordinarily greets the brilliant statements which are so customary when the virtues of a new remedy are detailed. No disease, perhaps, has given rise to more conflicting statements than pneumonia, and in no disease is it more important to guard carefully against erroneous deductions from favourable issues. Already numerous drugs have been given the credit of hastening the crisis or of cutting short the disease, and subsequent experience has shown that they do not merit the marvellous properties assigned to them. With regard to outward applications, however, there has been less difference of opinion, and although from time to time there have been indications of a wavering faith, there can be no doubt that in the profession and among the general public it has tolerably uniformly been held that as pneumonia is very commonly the result of a chill, so it is to be treated with poultices and hot fomentations as a matter of routine. In spite of the prevalence of this idea, it would be extremely difficult to find any sound basis for it. Most practitioners probably would defend the practice by referring to the relief given by hot applications, and would point, perhaps, to the fact that patients are rendered more comfortable, that the breathing is easier, and that perhaps a sound sleep may ensue. Some might go so far as to say that after the sleep the temperature fell and convalescence commenced, but in the majority of instances this would be arguing from *post hoc* to *propter hoc*.

Digitized by Google

In these days it is not seriously held that the application of poultices or hot fomentations can directly control the pathological changes which are the essence of pneumonia, still less is it believed that they have any power of curtailing the fever. They relieve pain and they satisfy the natural anxiety to do something in conditions of great apparent distress and danger, and for these reasons, perhaps, they have hitherto held their ground so securely, that in general practice it might be considered unwise to attempt to treat pneumonia without them. The disease is serious, it may prove fatal, and the general practitioner not unnaturally shrinks from unprofessional criticism of his treatment. We have mentioned above that this routine has not been allowed to pass unchallenged. Indications have not been wanting to show a growing tendency towards the treatment of pneumonia by cold applications, and at the last meeting of the Harveian Society an array of evidence was adduced in its favour. In another column a full account of the proceedings will be found, from which it will be seen that the subject of the treatment of pneumonia by the ice-bag was introduced by Dr. LEES, who, while strongly advocating this system of treatment, spoke with considerable caution of his results and their interpretation. From careful consideration of eighteen cases which had come under his observation, he concludes that in the treatment of pneumonia the ice-bag has a distinctly curative influence, which is not limited to a mere reduction of temperature, but extends to a repression of the inflammatory process in the lung. The cases he narrates are very instructive and suggestive, and from them it will be noted that although attention seems to have been very largely directed to pyrexia as a measure of the progress of the treatment, yet the physical signs were also carefully observed, and in the majority of cases underwent marked improvement. In other words, Dr. LEES does not recommend the employment of the ice-bag merely for the control of high temperatures; he believes that the benefits are not confined to this, and indeed he would appear to regard a fall of temperature merely as a side indication of a general amelioration. This hopeful opinion was scarcely endorsed by other observers, although there was unanimity of belief in the absence of risk when the cases were carefully watched, and any tendency to collapse controlled by brandy and warm applications. Further than this, it appears to have been the experience of all who spoke that the immediate result of the treatment was to give very marked relief from pain, to lower the temperature, reduce the pulse and the frequency of breathing, and to promote sleep. The tendency to drowsiness was mentioned in several of the cases narrated. When we look for ill results in the accounts given, they are not very apparent, or very serious. In no single instance was any extension of the inflammatory process attributed to the use of the ice-bag, and this is certainly a strong argument in its favour. On the other hand, the rapid fall of temperature seems in some few cases to have been followed by failure of the pulse, blueness, and coldness, and although these undesirable symptoms were readily controlled, and gave rise to no permanent anxiety, this warning is worth bearing in mind, more particularly perhaps in private practice, unless intelligent and skilled assistants are constantly watching the progress of the case.

Reviewing the whole discussion, it seems to be desirable that this method of treatment of pneumonia should be more generally studied, for it appears probable that in selected cases it may in time wholly replace the former routine of poultices. It has been found that fever and pain are both controlled by the ice-bag, while pain only is relieved by the poultice. It has also been found very generally that the sense of *bien-être* of the patient is improved, and that there is a relative freedom from risk if employed with due precautions. Whether subsequent study will tend to strengthen the position claimed for this treatment by Dr. LEES is another matter, upon which it might be rash to hazard a conjecture at present. Meanwhile, the fact remains that several careful observers, in their hospital work and occasionally in private practice, have tentatively been using a method which gives great relief, and is attended by no serious risks. The treatment will be sure to encounter opposition, the public having been so long accustomed to the employment of the poultice, so that the ice-bag may seem a sudden and violent measure in an unexpected direction. The conviction that the illness arises from a chill will also tend to render this treatment an apparent anomaly. Still, as a rule, most people bow before experience, and the safety we have above indicated should strengthen the hands of those in the profession who are not too much bound down by routine to welcome a new therapeutic measure.

THE prominence which was given, in the House of Commons, towards the end of last session, and by THE LANCET Special Sanitary Commission on the subject, to the destitute condition of the chain-makers in and about Cradley makes a report which Dr. GRESSWELL has recently prepared for the Local Government Board on the sanitary state of Cradley, and on enteric fever there, of especial interest. The place lies in the Stourbridge rural sanitary district, and it is at the onset described as one of those localities in the coal and iron districts of Worcestershire and Staffordshire which have long been known "for grave sanitary shortcomings and for prevalence of filth diseases." The inhabitants of Cradley numbered 5284 at the Census of 1881, and, in addition to those who are engaged in mining, both females as well as males are occupied in chain-making in small forge shops near to the cottages. Referring to drainage, we read of socketed pipes which are uncemented at the joints, of mere sewage tracks cut out by sewage on the surface, of sickening stenches from in-door drain-traps, and of pollution of the river by means of the highway drains, which were never intended to receive sewage. Where there are no drain channels, holes or cesspools, and even disused wells, are turned into receptacles for liquid filth. The large, open, deep, and dilapidated midden privy is general, and we read of this peculiarly offensive form of filth depository, together with privy vaults, piggeries, and swamps of liquid refuse, fouling the air breathed and soaking into wells, one of which had in its vicinity "open middens, piggeries, drains, sewage swamps, dumb-wells, and the like." Fortunately some extension of the water service belonging to the South Staffordshire Waterworks Company is in progress. But in addition to the use of rain-water, a hundred or more dwellings were, up to December of last year, supplied with water from the town well. As to this well, there was a

Digitized by Google

remarkable incidence of enteric fever on those who resorted to it, and in December, 1888, Dr. SWETE announced that it was largely polluted with organic matter. It was then closed, but it deserves notice that this very water-supply was emphatically pointed out to the sanitary authority by Dr. BALLARD in 1873 as a source of grave danger; that in 1877 and 1878 it was held by Dr. THOMPSON, the then medical officer of health, and by other medical practitioners, to have been the cause of an epidemic of enteric fever; that in 1880 Dr. PARSONS, visiting the district for the Local Government Board, spoke in no hesitating terms as to the danger attaching to its use; that the Vicar from his pulpit had declared that those who used it "were drinking dead men's bones"; and that, notwithstanding all this, it remained in use until, out of thirty-seven households invaded with enteric fever up to the end of 1888, thirty-three may be regarded as having got their infection from this water. But the general circumstances of the district were, apart from the original source of the fever, just such as to cause its diffusion. Water-supplies, says Dr. GRESSWELL, were in common use, although subject to risk of specific pollution; children were at play in the sewage gutters and about the heaps of filth on premises; and "poultry, at one moment investigating the filth out of doors, were at another mingling with the family in the cottage."

One piece of work appears to be done under some system, although not with the efficiency needed; we refer to the scavenging. But even as to this the Local Government Board were compelled in 1886 to issue a compulsory order requiring it to be performed under the provisions of Section 42 of the Public Health Act. Altogether, the story of this district and of its fever-diffusing circumstances is one of the sorriest we have for a long time come across. The medical men practising in the neighbourhood say that enteric fever is rarely absent; and between December, 1887, and June, 1889, 52 dwellings in Cradley proper were invaded; 113 out of a total of their 316 inmates, or 35·7 per cent., being attacked; and 16 of the latter, or 14·1 per cent., dying. There may be great difficulties in dealing at once with all the conditions inimical to health in this district, but it is impossible to accept any valid excuse for the long-standing neglect which this report has brought to light; and it is to be hoped that the inhabitants will, in view of their latest experience of fever in their midst, do their utmost to secure the election of a body of men on the rural sanitary board who will really carry out some of the urgent sanitary work which is so imperatively called for.

DR. F. W. BARRY'S examination (the fourth day) by the Royal Commission on Vaccination was concluded on Saturday last. He was, however, recalled on Wednesday, and gave further evidence. Staff Surgeon Theodore J. Preston, of the Medical Department of the Admiralty, was afterwards examined as to the success of vaccination in the Navy.

MR. E. WAYMOUTH REID, B.A., M.B. Cantab., M.R.C.S., Assistant Lecturer in Physiology, St. Mary's Hospital, London, has been appointed Professor of Physiology in the University College, Dundee.

Annotations.

"Ne quid nimis."

THE ROYAL COLLEGE OF SURGEONS.

THE report from the Council, comprising a record of their transactions during the Collegiate year, from July, 1888, to July, 1889, to be presented to the Fellows and Members of the College at the meeting to be held on Thursday next, Nov. 7th, at 3 P.M., has now been issued. Our readers will recollect that Mr. Jonathan Hutchinson has succeeded Mr. Savory as President, and he will preside at the meeting on the 7th, when the report is presented. Much of importance has passed at the College since the Fellows and Members met last year and asked for further consideration for the recommendations which they made as to an increased share in the management of the College, and renewed consideration of their claims with regard to the regulation of expenditure, right of meeting, and other matters. The resolutions passed at that meeting were not carried into effect by the Council, and a supplementary charter has been obtained with new bye-laws; and it was acting under these bye-laws that the election of members of the Council was carried out in July, proxy voting being permitted for the first time. Full information of the manner in which this was carried out is given in the report. We need not now enter into detail with regard to the expenditure of the Council, some of which, notably the amount spent in rebuilding the conservator's house, formed subject for comment at the annual meeting last year; but attention may be drawn to the report of the committee on the extension of the Examination Hall buildings, and the expense incurred in a dispute about "ancient lights," which led to an alteration of the original plans and a payment by the two Colleges of over £730. The rejections at the second examination induced the Council to pass a resolution to the effect "that the candidate be required to present himself for examination in anatomy and physiology together, until he has reached the required standard to pass in one or the other of those subjects; but no candidate will be allowed to pass in one of the subjects without obtaining at the same time at least half the number of marks required to pass in the other subjects." It was not considered advisable to make the performance of operations on the dead subject compulsory in the final examination for the Membership. A revised schedule of drugs (which we have already published in full) for the examination in Materia Medica and Pharmacy was agreed to, and at the same meeting of the Council it was agreed to give the title of Diplomate in Public Health to the possessor of the diploma of the Colleges. The Council did not think it advisable to hand over its penal powers to the General Medical Council; it did not consider any extension of the powers of the General Medical Council necessary, neither did it consider it expedient to obtain power to temporarily remove a Fellow or Member, such being already provided for in the bye-laws; it proposed, however, to increase the powers already possessed, and to make the definition of misconduct extend to "cases of infamous conduct in any professional aspect." Two members of the College have been removed from the Register under Clause 2, Section 16, of the bye-laws. Mr. Sibley reported the completion of the conference on the medical scales in use on passenger ships, and Mr. Macnamara was appointed to represent the College on Lord Camperdown's committee of inquiry into the pay, status, and conditions of service of the medical officers of the Army and Navy. There is one important subject on which we do not propose to offer any comments, as it has been brought under the

Digitized by Google

consideration of the Court of Chancery, and that is the question as to the right of Fellows and Members to meet on the premises of the College, and whether this can be done without the consent of the Council; it will be recollected that this question was raised by the attempt to hold a meeting in the College on Feb. 28th of the present year.

THE OXFORD CITY CORONER AND THE RADCLIFFE INFIRMARY.

AT the Radcliffe Infirmary, on Oct. 19th, an inquest was held touching the death of a domestic servant named Hannah Mary Honour, aged eighteen years. From the evidence, it appears that previously to her fatal illness she was not known to have suffered from any serious indisposition. Two days prior to being admitted to the Infirmary she complained of headache and sickness. The symptoms developed until her condition caused alarm, and a local practitioner was called in. This gentleman, recognising the gravity of the case, which he diagnosed as one of brain disease, very properly advised her immediate removal to the Infirmary. On admission to that institution, Dr. Rice, the resident physician, made such examination as enabled him to come to the conclusion that the patient was suffering from blockage of some of the cerebral arteries; indeed, some of the symptoms were indicative of a coarse one-sided lesion of the brain. In addition to Dr. Rice, the house surgeon saw the patient, and concurred in his opinion. Dr. Rice obtained permission from the parents of the deceased to make a necropsy. The post-mortem signs corroborated his diagnosis, and he gave a certificate of the cause of death. Mr. Hussey, the city coroner, decided to hold an inquest, and during the investigation animadverted strongly (1) upon the fact that the patient was not seen by one of the honorary medical staff; (2) that a post-mortem examination had been made without his knowledge and permission; and (3) that he had not been informed by the governing authorities of the infirmary that the deceased had died under such circumstances as to necessitate a public inquiry. We have many times had occasion to advocate the holding of inquests in all cases where the cause of death was doubtful, and shall continue to do so; but in this case, if we are correctly advised, we cannot see that it was either necessary or expedient for an inquest to be held, and consequently, in our opinion, neither the medical officers nor the governing body of the institution were under any obligation to lay any information before the coroner. The case was diagnosed during life as one of natural disease of a determinate character. The post-mortem examination verified the conclusion arrived at by observation of the symptoms. Acting upon our information, we unhesitatingly endorse the action of the Infirmary governing authorities and that of its medical officers.

THE ITALIAN MEDICAL CONGRESS.

FOLLOWING up an excellent initiative, the promoters of this annual assembly of the physicians of Italy have decided on three subjects for special discussion at next year's Congress. These are (1) the Ætiogenesis and Treatment of the Various Forms of Pleurisy; (2) Hæmodyscrasia in all its Varieties; and (3) Multiple Polyneuritis. As on the recent occasion, each of these subjects will be committed to two physicians, one of whom will make a special study of it on its pathological side, and the other on its clinical or therapeutic side; they will embody their conclusions in a joint report which they will read before the Congress; and, having thus started the general discussion, they will both reply on the whole case. This announcement of the main features of its programme a year in advance has, among other advantages, that of enabling members of the Congress to come prepared for intelligent appreciation and discussion of the specified subjects—to the great economy of time by the minimising of discursive or irrelevant matter. Another commendable arrangement, on the part of the promoters of the Congress, is the issuing from day to day of an official report of the proceedings—a report framed from shorthand notes, and revised by the authors of the memoirs and their critics. It was found that the lay press were apt to be either too curt or too diffuse in its summaries of the sittings — curt where the author or his critic was not a *persona grata* to it, and diffuse where it had reasons, often unprofessional, for showing partiality. The official report, which will now be handed after each sitting to the lay journals, will obviate this abuse. Yet another arrangement, on which the promoters have had just cause for congratulation—the facilities they have obtained from Government for enabling the medical students from every Italian seat of learning to be present at the Congress. The numerous contingent of young and eagerly attentive listeners contributed from Turin and Palmero, from Padua and Naples, was a pleasing trait of the last meeting at Rome, and seemed to react beneficially on the interlocutors themselves, in recalling them from the transcendental and the "*à prioristic*" to the inductive and the practical in their expositions. It is, indeed, the avowed object of the Congress for "Medicina interna"—or "innerf Medizin," as its Teutonic prototype calls it—to form a distinctively "Italian school," in the sense in which there is a British, a German, a Russian, and a French school; and it seeks to hasten this result by familiarising the student-mind, at as early a stage as is practicable, with the value placed on original research and independent opinion in medicine. The aim is an honourable as well as arduous one, and deserves the countenance and sympathy of all who are impressed with what Italy was in the past, and with what she may again become in the future.

TYPHUS IN IRELAND.

THE Registrar-General's recently issued Annual Report for Ireland shows that the death-rate from typhus in that country, although it continues to decline, still shows a remarkable excess compared with that which prevails in other parts of the United Kingdom. It appears that, during last year, 362 fatal cases of typhus were registered in Ireland, against 405 in 1887. The deaths from this disease were more than twice as numerous as they were in England and Wales during the last two years; and if due allowance be made for the difference in population, the mortality from typhus appears to have been during the two years under notice more than ten times as great in Ireland as in England and Wales, notwithstanding the far more dense aggregation of the urban population in England. With regard to the mortality from typhus in Ireland in recent years it may be pointed out that in 1881 the death-rate was 167 per million (against 21 in England), but has since pretty steadily declined year by year, the rate in 1888 being reported as 76 per million. While typhus mortality in Ireland has thus steadily declined, being in 1888 considerably less than half what it was in 1881, the death-rate from enteric or typhoid has remained almost constant. The death-rate from enteric fever in England has steadily declined in recent years, but it still exceeds the rate that prevails in Ireland. With reference to the distribution of fatal typhus in Ireland, it appears that of the 362 deaths referred thereto in 1888, 143 occurred in Munster, 83 in Leinster, 70 in Ulster, and 66 in Connaught; the proportion per million of the population being 107 in Munster, 80 in Connaught, 65 in Leinster, and 40 in Ulster. Thus it would appear that in Ireland the mortality from typhus is almost in inverse ratio to the

Digitized by Google

density of population. Of the 143 fatal cases of typhus registered in Munster in 1888, the following counties showed the greatest numbers—Cork, 63; Waterford, 28; Limerick, 18; and Kerry, 18. This continued prevalence of typhus among the population of Munster, most of which is essentially rural in character, affords a most unsatisfactory commentary upon its sanitary condition.

THE SANITARY REGULATION OF HOUSES.

THE London County Council decided last week to make application to Parliament for powers to be vested in vestries and district boards in the metropolis, to enable them to undertake the periodical examination of drains beneath houses, and for the execution of such works by them as upon such inspection or otherwise may in their judgment seem necessary. We have received from Mr. Mark Judge a long letter, protesting against this resolution, and urging that the local sanitary authorities are unfit to be entrusted with these powers. He expresses the opinion that their own procedure should be limited to registering the certificates of other persons than their own officers, and that these officers should not themselves undertake the work which is proposed. On this point we are completely at issue with Mr. Judge. The surveyors of vestries and district boards may not all be experts in this particular branch of house construction, but London householders would be much safer in their hands than in those of the numerous so-called sanitary engineers who would be suddenly called into existence if there were a general demand for the reconstruction of all house drains whenever these may be faulty. We presume that some agreement would be come to as to the conditions with which every house would have to comply, and the regulations as to house-drains which it is expected the London County Council will make will afford a convenient basis. We do not believe for one moment that it will be possible to insist upon the drains of every house in London being raised in respect of wholesomeness to the position of drains of houses built often after the making of bye-laws as to house drainage. The change and improvement must necessarily be gradual, but the vestries and district boards may be expected to do something towards attaining this end, and still greater expectations may be had of the district councils which will be called into existence when these bodies are constituted. For our own part we would far rather trust to officers appointed by these authorities than to irresponsible persons of whose knowledge and efficiency there would be absolutely no guarantee.

CREMATION IN SOUTH GERMANY.

THIS substitute for the traditional mode of interment is gaining ground in Germany, and now the Communal Council of Munich are considering whether the time is not ripe for its recognition in practice. Eleven years ago the board of health of that city commissioned Dr. von Kerschensteiner to report on cremation, and the conclusions to which he came were the following: In general cremation is not only to be permitted but even to be recommended, especially after great battles; in certain cases (subject to official authorisation) of epidemic disease, for the prevention of the transport of corpses, and in the case of soil conditions contra-indicating the inhumation of the dead. Munich, indeed, from the standpoint of public health is, Dr. von Kerschensteiner holds, under no special need of introducing cremation, but, at the same time, there is no ground for not permitting it, after official cognisance of the circumstances attending each individual case of death, and under certain determinate precautions. Of these latter, the first, according to Dr. von Kerschensteiner, must require the handing in, on the part of the responsible practitioner, of a complete medical history of the case—this report to be revised by the public medical officer in charge of the police regulation of dead bodies, and thereafter to be deposited with the judicial authorities. The second precaution must be the undertaking of a complete *sectio cadaveris* by a well-instructed pathological anatomist officially appointed for the task (the "Städtische Prosector"), and the deposition of his post-mortem report with the judicial authorities. Thirdly, there must be continuous numeration of the incinerated residue of each corpse, the checking such residue by a mark, and the deposition of this with its corresponding number for judicial purposes. These precautions and conditions are stringent, and the Communal Council of Munich contemplates no more than the optional sanction of cremation. Experience alone can determine their efficiency, whether they may not in some aspects be relaxed, or whether they may not be made yet more stringent. By that experience, say German sanitarians, the State will be guided in converting optional into compulsory vaccination.

FEVER AND WELL-CLEANSING AT SILEBY.

THE Barrow Board of Guardians, in their capacity of rural sanitary authority, have had under consideration a prevalence of enteric fever at Sileby. The case is evidently one of many showing how often grossly defective sanitary conditions are allowed to remain until after the occurrence of infectious disease, which it is a principal object of sanitary government to prevent. In the outbreak under consideration foul water, dirty yards, and a defective drain passing under cottages have all been detected now that fever has prevailed, and a number of measures are being taken to secure the abatement of the conditions referred to. The story is a very commonplace one, and we note it not because it presents any peculiarities, but because of one measure of prevention, so called, that is stated to be in contemplation. We learn that when the well for the domestic supply of the affected cottages has been found contaminated, orders have been given by the owner to have it "thoroughly cleansed." A more meaningless piece of work can hardly be conceived. There is another well close by which a committee report as "very bad," and it is suggested that possibly its contents find their way into the well used for domestic purposes by the cottages. And the remedy in contemplation is to clean the inside of a well which receives its polluting matter from outside—namely, from the soil and the ground water around it. Surely the time has come for erasing the cleansing of wells under such circumstances from the vocabulary of "sanitary" work.

A DISPUTED HOSPITAL LEGACY.

MR. JUSTICE MATHEW has been called upon to decide a somewhat nice question as to the proper construction to be put upon certain words contained in a will. The testator had left one-tenth part of his residuary estate to "the Eye and Ear Infirmary situate in Liverpool," but the question was which of the two, the Liverpool Eye and Ear Infirmary or the St. Paul's Eye and Ear Hospital, was the one meant. The former is a combination of two institutions founded nearly half a century ago; the latter is of more recent creation, being established in St. Paul's-square, Liverpool, within the last twenty years. The judge of the Westminster County Court decided in favour of the older institution, which at first sight would appear to resemble in its title the institution named in the will. But this decision was appealed against, and in the Queen's Bench on the 25th ult., Baron Huddleston and Mr. Justice Mathew held that there was ambiguity in the

Digitized by Google

bequest, and that the county court judge should have admitted evidence to show what it was the testator meant. It was also arranged that Mr. Justice Mathew should look at the statements in certain affidavits, and say which institution he thought was entitled to the bequest. He gave his decision on the 25th ult. in favour of the St. Paul's Hospital. The testator had concerned himself about its management; he knew the medical officer, and he had repeatedly subscribed to it. Mr. Justice Mathew thought, therefore, that the St. Paul's Hospital was abundantly identified as the institution which was to be benefited by the bequest. The decision of the county court judge was accordingly reversed.

PROPOSED ABOLITION OF ONE OF THE BRUSSELS HOSPITALS.

A MOVEMENT is on foot to abolish one of the two great Brussels hospitals—viz., the Hôpital Saint-Jean,—and so to throw the whole burden of providing for the sick poor on the Hôpital Saint-Pierre. The object is of course to save expense, it being alleged that since the establishment of suburban hospitals the expenses have been the same as they were before for these two great hospitals, though there has not been the same number of patients, many having been drawn off by the newer and smaller institutions. According to the published figures, which, however, are said not to be quite accurate, the Saint-Pierre contains 681 beds and the Saint-Jean 644, making altogether a total of 1325, in which are included twenty-seven beds for paying patients. The population which this has to serve is 182,000. The proposal to abolish the Saint-Jean is severely criticised in *La Clinique*. The writer calculates that if all the special departments of the Saint-Jean are to be transferred to the Saint-Pierre, there will only remain 190 beds left for the general medical and surgical cases—a number obviously far too low, as on one day last year the number of medical and surgical cases actually in the two hospitals was 593, so that under similar circumstances the hospital accommodation of the future would be 403 beds short. The only way of obviating this would be to enlarge the Saint-Pierre to such an extent that the new building would be equivalent to a new hospital of considerable size. Another objection to the proposed plan is that in case of an epidemic it would be impossible to transfer all the ordinary cases to one of the hospitals and make use of the other as a means of isolation. Even from the university point of view it is a good thing to have two institutions, as their courses and clinics are presided over by different teachers, between whom there must necessarily be a certain amount of honourable rivalry which is for the advantage of the students and for that of science generally.

EXTRA-GENITAL SYPHILIS IN MOSCOW.

PROFESSOR POSPELOFF of Moscow has recently published in pamphlet form an account of the extra-genital syphilis which he has met with amongst the working-class population in Moscow. He has seen a great many more of these cases amongst women than amongst men, the actual figures being fifty-two male and 146 female cases, notwithstanding the fact that there are many more male than female patients in the hospital with which he is connected. The greater prevalence of this class of affection amongst women than amongst men is accounted for by the domesticated habits of the women, and more particularly by their receiving the infection during suckling. The most common seat of these non-venereal sores is the mouth. This kind of infection is mainly due to the dirty habits of the people, who habitually eat together out of the same vessel, and even with the same wooden spoon, which, if any of the persons using it are syphilitic, soon becomes a fruitful source of infection. Again, it is found that in small factories and sewing shops the workwomen very frequently suffer from extra-genital syphilis, showing that cleanliness and sanitary supervision are very defective. Prof. Pospêloff has collected a large number of references to the works of other authors in English, French, German, and Russian, which will be found in the appendix to the paper.

THE VICTORIA CROSS.

WE are glad to be able to congratulate the Army Medical Staff upon another of its members having gained the coveted distinction of the Victoria Cross, and to felicitate the recipient, Surgeon Ferdinand Simeon Le Quesne, upon whom, according to the *London Gazette*, "the Queen has been graciously pleased to signify her intention to confer the decoration of the Victoria Cross for conspicuous bravery and devotion to duty displayed during the attack on the village of Tartan, Upper Burma, by a column of the Chin Field Force, on May 4th, 1889, in having remained for the space of about ten minutes in a very exposed position (within five yards of the loop-holed stockade from which the enemy were firing) dressing, with perfect coolness and self-possession, the wounds from which Second Lieutenant Michel, Norfolk Regiment, shortly afterwards died. Surgeon Le Quesne was himself severely wounded later on, whilst attending to the wounds of another officer." Ferdinand Simeon Le Quesne, who will be only twenty-five years of age in December next, entered the medical department of King's College in October, 1881, and, having filled the usual clinical appointments, qualified as L.S.A. in 1885, M.R.C.S. Eng. and L.R.C.P. Lond. in January, 1886. He at once successfully competed for admission into the Army Medical Service, and after the usual curriculum at Netley, obtained his commission in July, 1886.

THE NOTIFICATION ACT AND LOCAL AUTHORITIES.

THE smoothness with which this important Act will work will greatly depend on the pains taken by the local authority, and especially by the medical officers of health, to facilitate the duty of notification by the medical practitioner in attendance. We have received copies of four enclosures sent to each practitioner in the Chelsea district by Dr. Edward Seaton, medical officer of health. First, a book of certification forms, very neatly arranged with a counterfoil to each page for recording particulars of each case notified; secondly, a map of the district; thirdly, an outline of the Notification Act; fourthly, a handbill relating thereto. Dr. Seaton further very kindly expresses his willingness to supply any further information that may be desired. We cordially commend such courteous action on the part of Dr. Seaton to the imitation of other medical officers of health. The duties imposed by the Act to busy practitioners will be irksome, but this irksomeness may be much reduced by such measures as have been taken so promptly in Chelsea.

THE GUINEA-WORM IN EUROPE.

THE Guinea-worm, or filaria medinensis, is not usually seen in northern Europe, but of course European travellers or natives of some Asiatic or African countries may bring it. A Brussels practitioner, Dr. Robinet, has recently had two patients suffering from this parasite amongst the members of a troupe of negroes from Accra, on the Guinea coast, who have been performing in Brussels this year. In both cases the worm was in the leg, and was removed in due time, after the cautious opening of the pustule which it produced, by the process of winding it very gently round a match.

DEFECTIVE PRACTICAL TEACHING IN GERMANY.

A DISCUSSION has been raised of late concerning the want of practical medical knowledge on the part of German medical students, and a paper bearing on this question appeared in the *Aerztl. Central Anzeiger* of Sept. 30th last. The author avers that the Germans are far behind their neighbours in the practical instruction given in the medical schools. This defect he traces partly to the individual peculiarities of the nation, and yet more to the history of medicine within the last thirty or forty years in Germany. As long as medicine was an abstract science the methods of instruction differed little essentially from those required for other learned professions. But natural science now began to claim attention from the votaries of medicine; the dissecting room, the laboratories, and hospitals became the foci of interest; philosophical reasoning and speculation were abandoned for practical observation and experiment, and in Germany the two things did not advance *pari passu*. It followed, therefore, that a completely different mode of instruction was necessary. Formerly physiological, pathological, and pharmaceutical institutes did not exist, but in the present day there is no medical school in Germany without them. It is clear that the doctors of the future must not only be grounded in the principles and science of medicine, but they must have a practical knowledge of it. The instruction given in German schools is deficient in this latter element. Modern medicine is primarily a technical art. Diagnosis requires a multitude of technical manipulations which cannot be learned by mere book knowledge or by a process of reasoning. Three forms of instruction are necessary for the acquirement of this dexterity—first, the preparatory theoretical studies combined with corresponding lectures; secondly, demonstrative instruction, such as is demanded for clinics; and thirdly, practical experience under a fully qualified teacher. This last form of instruction is defective in Germany; many of the students who leave the medical school have never had a leech or a cupping glass in their hands. The medical profession stands alone in its requirements. Members of other professions can always have recourse to books in cases of necessity; but the medical man needs something more than book knowledge, and if he has not attained manual dexterity before his entrance on his profession, he feels very much at a loss. The author of the paper referred to proposes that the professors should devote a little less time to consultations, so that it would be possible for them to train the students in eight or nine sessions to act as junior medical officers in the hospitals. He also recommends at least one year's further study at a university, in order that the student may apply himself to hygiene, mental disease, medical jurisprudence, and the history of medicine.

INVOLUNTARY AUTO-INOCULATION OF GLANDERS.

A PAINFUL CASE was reported by the Vienna correspondent of the *Daily News* on the 28th ult., of the death of a young physician, Dr. Hoffmann, from glanders, under the following circumstances. In August a man suffering from glanders was admitted into the General Hospital, and Dr. Rowalski studied the case bacteriologically, isolating the bacillus, cultures of which he gave to Dr. Hoffmann, who was sceptical as to the transmission of the disease by inoculation of the cultures. The latter's experiments made with the cultures, however, convinced him of their continued virulence. In the beginning of October he took cold, and had severe pain in the side, for which he had recourse to morphia injection, using the same syringe he had employed in his experiments. The syringe had been heated to redness, and was thought to have been thus thoroughly disinfected; but that it must have retained some of the virus in an active state seemed to be proved by the melancholy sequel of the unfortunate physician becoming infected with glanders, from which he died. The account forwarded to the *Daily News* is circumstantial, although somewhat sensational. Assuming the facts to be as related, the moral of the case is obvious, showing the disastrous consequence of a thoughtless use of the same instrument as that employed for experimental inoculations and hypodermic medication. It demonstrates also the virulence of the glanders poison, and suggests the difficulties that may beset experimenters in ridding their instruments of all traces of the virus with which they deal.

LENIENCY OF THE BELGIAN MATRICULATION

FOR some time past an agitation has been taking place in Belgian medical circles, with the object of getting the portals of the profession narrowed, as the amount of overcrowding is felt as seriously in Belgium as it is here. It is considered by many of those who have expressed themselves on the subject that not only should the professional examinations be increased in severity, but that the matriculation or entrance examinations in the medical faculties of the four universities should also be rendered more stringent. Some legislation in this direction has been expected for several years past, the consequence of which is that there has been rather a rush of students eager to matriculate before the new regulations are made, so that they may get the benefit of the old—i.e., the present—lenient system. As an illustration of this leniency, it was stated recently at the meeting of the Medical Federation that at one of the *athénées*, or classical public schools, fifteen of the boys who failed to pass the examination necessary for promotion from the *quatrième* (which is about equivalent to an English third form) to the *troisième* (equivalent to the fourth form) had matriculated at the university.

THE PUBLIC HEALTH DURING THE PAST SUMMER.

THE Registrar-General has just issued his quarterly return dealing with the vital statistics of the third or summer quarter of this year. The annual death-rate in England and Wales during the three months ending with September last was equal to 16·7 per 1000 of the estimated population. Although 1·7 above the unprecedentedly low rate in the corresponding quarter of 1888, this rate was 0·8 below the average rate in the third or summer quarters of the ten years 1879–88. The death-rate in the summer quarter of the year is mainly governed by the mortality from infantile diarrhœa, which is essentially an urban disease. We find, consequently, that in the aggregate of the urban population of the whole country the death-rate was 17·8, whereas in the remaining and chiefly rural population it did not exceed 14·7. In equal numbers living, therefore, the deaths among the urban population last quarter were 121, to 100 in the rural population. The excess of urban mortality was, however, below the average for the season. In the twenty-eight great towns, with an estimated population not far short of 10,000,000, the death-rate was 18·6. In London the rate did not exceed 16·5, while the mean rate in the twenty-seven provincial towns was 20·4. The rates in these provincial towns ranged from 14·2 and 14·4 in Derby and Brighton, to 26·6 in Plymouth, 27·6 in Newcastle-upon-Tyne, and 33·0 in Preston. In fifty other town districts, with an aggregate population of nearly 3,000,000, the mean rate was 17·9, and only slightly above the general urban rate. Speaking generally, the mortality

Digitized by Google

from the principal zymotic diseases was below the average. This was markedly the case with small-pox (which caused but two deaths in the whole of England and Wales during the quarter), scarlet fever, and fever; the death-rate from diarrhœa was also slightly below the average. The mortality from diphtheria and measles showed an excess, while the rate from whooping-cough corresponded with the average. The death-rate from diarrhœa (1·67 per 1000) was nearly double that which prevailed in the exceptionally cold and wet summer of 1888, although slightly below the mean rate in the corresponding periods of the ten years 1879–88. The diarrhœa rate was but 1·16 in England and Wales, exclusive of the seventy-eight largest town districts, while it was 2·46 in the twenty-eight great towns. In these twenty-eight great towns the diarrhœa rate last quarter ranged from 0·49 and 1·00 in Halifax and Huddersfield, to 4·63 in Sunderland, 4·94 in Leicester, and 7·36 in Preston. This startling contrast is as completely without satisfactory explanation as it was ten or fifteen years ago, when infantile diarrhœa mortality first began to attract serious attention. The Registrar-General's health bulletin for the past summer is, on the whole, satisfactory, and it is especially encouraging to find that the mean English death-rate for the first nine months of this year is slightly lower than the rate in the corresponding period of 1888, which was far below the rate recorded in any previous year of which satisfactory records exist.

THE SPREAD OF SCARLET FEVER.

A PARAGRAPH in a daily paper last week gives an account of an inquest held in Mile-end, which illustrates very forcibly the manner in which scarlet fever spreads. A child died of scarlet fever in St. Ann's-road. No medical man was called in. Another child in the same family suffered from the same disease, as well as three other children in another family resident in the same house. In the next house another child also was attacked with scarlet fever. The grandmother of the dead child made matchboxes, and the mother of the three sick children was a tailoress, and each carried on her work in the rooms where the children were. The preceding Tuesday a child in a house in Canal-road died of scarlatina, and the mother, a cigar maker, had been engaged in her occupation during the child's illness, while another child was attending the school at the time. All this is the record of one district, and if the facts were known, we do not doubt that similar illustrations might be found in other parts of the metropolis. We may hope that the new Act, which came into force on Oct. 31st, will do something towards limiting the risk of injury from such occurrences, but it is obvious that the education of the poor is an essential element in any measures that may be taken for improvement in this direction. The story told in "Alton Locke" is not exceptional at the present time.

HAIRDRESSING AND CONTAGION.

WHETHER it be founded on fact or not, an accusation brought by certain members of the medical faculty in Paris against the guild of hairdressers conveys a caution which ought not to be undervalued. The ease with which ringworm and other contagious disorders may be communicated by means of soap, razors, and other kindred appliances, is generally understood. That such contagion has not uncommonly been conveyed in this way is also indisputable. It does not follow, of course, that the operators belonging to the Parisian corporation have been special offenders in this respect, and we do not doubt that in France, as in England, the precautions observed by most respectable hairdressers are sufficient for the protection of the public. Still, the fact that there exists a form of disease truly described as regards its mode of transference by the name of "barber's itch" proves that due care and cleanliness are sometimes wanting. Yet the accidents occasioned by such neglect are easily preventable. An excellent rule with some barbers is to attend any contagious cases at their own homes, a distinct set of instruments being used for these visits. This implies of necessity some acquaintance with the characters of parasitic disease. The substitution for soap of saponaceous cream, a separate portion of which can be applied in different cases, affords another safeguard. After all, however, it must be remembered, even in the cheap shop with overflowing custom, that the fundamental guarantee of safety consists in cleansing each instrument used after each time of use. Whatever the verdict of public opinion on the practice of the coiffeurs in Paris, there cannot be two opinions as to the essential value of the precautions indicated by our professional brethren in that city.

ASSOCIATION OF MEMBERS OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

WE are informed that the subjoined resolutions will be proposed on behalf of the Association at the meeting of Fellows and Members on Nov. 7th, 1889:—1. That this meeting of Fellows and Members of the Royal College of Surgeons of England having considered the report of the Council, dated Oct. 17th, 1889, is of opinion that immediate steps should be taken to forward the introduction early in the next Parliamentary session of a Bill to amend the constitution of the College, so as to secure to the Members a just representation in and upon the governing body of the College; and that a committee be hereby appointed to co-operate with the central committee of the Members' Association in taking the necessary steps to give effect to this resolution. 2. That the following gentlemen [to be named] be appointed members of the committee, with power to add to their number.

REGINA v. MOON.

AT the Central Criminal Court on the 30th ult., after three days' trial, Dr. Moon, a medical practitioner of Greenwich, who was indicted for having caused the death of a woman named Tebbutt by procuring abortion, was acquitted by the jury of all the charges preferred against him. Mr. Justice Fitzjames Stephen, who tried the case, concurred in the verdict. Counsel for the defence did not call any witnesses, Mr. Lockwood, Q.C., stating that he was quite satisfied to accept the medical evidence supplied by the prosecution. The learned judge, in his summing up, endorsed this step, and said the medical witnesses for the prosecution had given their evidence with great fairness. We shall discuss the case at length in our next issue.

EXPERIMENTAL ARTICULAR TUBERCULOSIS.

DR. PAVLOVSKI, in a paper recently published in the *Vrach*, gives an account of some researches he had made in Professor Pasteur's laboratory on the development and spread of articular tuberculosis, his special object being to find out whether the tubercle bacilli develop in the white corpuscles or in the connective tissue or in both. In order to carry out his research he prepared cultures of tubercle bacilli in peptone glycerine and injected the virus into the knee-joints of guinea-pigs, these joints being examined after the lapse of from half a day to eight weeks. After twelve hours the bacilli could be detected both in the connective-tissue corpuscles and in the white blood corpuscles. It was found that the white corpuscles play an important *rôle* in the production of tubercle, undergoing a series of progressive changes until they assume an epithelioidal character, experi-

Digitized by Google

mental tubercle consisting of epithelioidal cells due both to white blood corpuscles and to connective-tissue corpuscles. Dr. Pavlovski was also able to demonstrate the propagation of the bacilli along the course of the lymphatics, the nearer glands becoming first infected and subsequently those at a greater distance.

ANOTHER BOGUS DIPLOMA MILL IN THE UNITED STATES.

THE *Chicago Times* reports that a great sensation has been produced in Portsmouth, New Hampshire, by the discovery of another actively maintained bogus College of Medicine, similar in management to and larger in extent than the one fully exposed a few years ago. It is stated that any person having the necessary money could have a diploma in medicine and surgery from various institutions named which exist only on paper. The discovery of the fraud has been made by Dr. D. S. Adams, Chairman of the State Board of Censors. The whole subject is now under investigation by the authorities of the State. It is of great moment for the United States that all such cases should be thoroughly exposed, and that Congress itself should take some steps to maintain the standard of medical education and to punish fraudulent dealers in degrees and diplomas. We shall be glad to ascertain the result of the investigation.

PYOSALPINX AND LAPAROTOMY.

IN some clinical remarks recently published by Dr. Richelot in *La Semaine Médicale* (and commented on by M. Verchère in *La France Médicale*, No. 124), the indications and contraindications for laparotomy in pyosalpingitis are pointed out. These, he says, largely depend on the duration of the disease. A simple acute or subacute salpingitis may get well spontaneously or by simple means; whilst it is as much an abuse to remove an ovary simply because it is inflamed as it would be to castrate for orchitis. In his cases an interval of two years from the onset of symptoms is, *cetœris paribus*, allowed to elapse before removing organs which by that time would have become useless. Severity and constancy of pain, especially in labouring women, would perhaps justify interference. Of course, wherever the presence of pus can be found, surgical interference is called for, to obviate pelvic peritonitis and worse evils. The advice of some surgeons to wait for the spontaneous opening of the abscess is deprecated, and so is the proposition (in imitation of the usual course followed by nature in spontaneous cures) to operate through the vagina rather than directly through the peritoneum.

TRISMUS FOLLOWING VACCINATION.

IT is reported that at Bromley recently an infant who had been vaccinated in September, at the same time and with the same lymph as six other children, had died of trismus, which had supervened upon inflammation of the arm. With the scanty details at present forthcoming it is impossible to pronounce upon the case as to the possible connexion between the vaccination and the trismus, an association which has, we believe, never been hitherto recorded. In such a case the need of a post-mortem examination is obvious, in order to exclude meningitis, which might have produced the symptoms in question.

THE MUZZLING ORDER.

AT the usual weekly meeting of the London County Council on Tuesday last, the Parks and Open Spaces Committee reported that they had received a letter calling attention to the number of unmuzzled dogs which were at large on Hampstead Heath and Parliament Hill, and suggesting that the keepers in the service of the Council should be instructed to enforce the muzzling order with respect to dogs in those two places. A recommendation of the Committee was adopted that the writer of the letter be informed that it was the duty of the Metropolitan Police to see that no unmuzzled dogs were at large on Hampstead Heath, that being a "public place" under the Act of 1871; whilst as regarded Parliament Hill, the Council had not yet obtained possession of the land.

THE CHAIR OF ANATOMY AT ABERDEEN.

THE Queen has been pleased, on the recommendation of the Secretary for Scotland, to appoint Mr. Robert W. Reid, M.D., C.M., F.R.C.S., to be Professor of Anatomy in the University of Aberdeen, in the room of Professor Struthers, resigned.

FOREIGN UNIVERSITY INTELLIGENCE.

Berlin.—The charge of the physical department of the Physiological Institute, of which Professor du Bois Reymond is director, has been entrusted to Professor Arthur König.

Caen.—Dr. Barette has been appointed to the chair of Clinical Surgery.

Copenhagen.—The number of students commencing their studies is forty-four.

Grenoble.—Dr. Gallois has been appointed to the chair of Midwifery and Gynæcology.

Warsaw.—Dr. Laptschinski has been promoted to be ordinary Professor of Pathology and Therapeutics.

DEATHS OF FOREIGN MEDICAL MEN.

THE deaths of the following eminent foreign medical men are announced:—Dr. Georg Hofmann von Wellenhof, assistant to the professor of hygiene in Vienna, from glanders. Dr. Lafitte, formerly physician in the French lunatic asylum service.

DR. W. S. CHURCH, Christ Church, has been appointed to represent the University of Oxford on the General Medical Council, in the room of Dr. King Chambers, deceased.

THE Harveian Lectures, on the "Surgery of the Kidney," will be delivered by Mr. Knowsley Thornton, F.R.C.S.Eng., on Nov. 21st and 28th and Dec. 5th.

AT the next meeting of the Medical Society, on Nov. 4th, Sir Joseph Lister will give an address on a New Antiseptic Dressing.

Pharmacology and Therapeutics.

CODEIA IN GYNÆCOLOGICAL PRACTICE.

DR. FREUND of Strasburg, who was induced by the favourable opinion of Professor Schröder on the suitability of codeia for the treatment of pain in diseases of the female genital organs to give it a trial, has published the results of his experience in the *Therapeutische Monatsheft*. He remarks that Dr. Lauder Brunton's testimony to the value of codeia in pain affecting the lower portion of the abdomen must be accepted in gynæcological practice with considerable limitations. He found that pain originating in the uterus, and depending upon either acute or chronic affections of that organ or upon dysmenorrhœa, was only affected in a very transitory way by codeia, and never to nearly the same extent as by opium or morphia. Extensive effusions, too, into the pelvic peritoneum or into the cellular

Digitized by Google

tissue were but little improved by codeia, and the same might be said of diseases of the tubes. On the other hand, however, he found that it exerted a true, unmistakable and immediate effect upon pains of all sorts having their origin in the ovaries, whether there was displacement, prolapse, ovaritis, peri-ovaritis, or the so-called "ovarian neuralgia." In all these cases codeia, even in small doses, appeared capable of exercising a marked control over the pain, and in many cases of arresting it altogether. Of course suitable local and dietetic treatment was applied simultaneously. As to the doses given, the usual plan was to order a pill containing half a grain of codeia made up with gentian and liquorice, to be taken three times a day. Occasionally larger doses had to be given. In no case, however, was any unpleasant effect observed, and there were no signs of any cumulative action, some of the patients taking these pills for a month.

RESORCIN IN WHOOPING-COUGH.

Dr. Justus Andeer, who had previously written in recommendation of the employment of resorcin in whooping-cough, has recently published some fresh cases illustrating, as he believes, the advantages of this method of treatment. One of the patients was his own child, a little girl of seven years of age, who during an epidemic of measles and whooping-cough was attacked by the catarrhal form of the latter affection and suffered severely for a week, notwithstanding a change of climate. He then prescribed an ounce of a 2 per cent. solution of resorcin four times a day, part of which solution the child was to gargle, and part of which she was to take. This very soon began to show signs of affecting the course of the disease, for on the second day the fits of coughing very perceptibly diminished, and in eight or ten days the child was quite free from cough. Five other children, who had been unsuccessfully treated for some time, immediately began to improve under the resorcin treatment. In the case of a baby of six months old a sweetened solution of the strength of ½ per cent. was given by means of a feeding-bottle and answered admirably.

PEREIRIN AND QUININE IN MALARIAL FEVER.

Dr. Tibiriçá, physician to the Hospital Santa Veridiana in S. Paulo, Brazil, publishes in the *Revista Medica de S. Paulo* a paper on the "Advantages of employing Pereirin as an Adjuvant and as a partial Substitute for Quinine in Malarial Fevers." In cases where the heart is affected large doses of quinine are dangerous, and the combination of digitalis with quinine has, in Dr. Tibiriçá's hands, proved very unsatisfactory. Pereirin, however, according to his experience, appears to augment the proper action of quinine without exerting any serious depressing effect on the heart. Instead, therefore, of prescribing quinine alone in 15 gr. doses, he orders 7½ gr. of quinine combined with an equal quantity of pereirin, a combination which appears to exert the same effect over the malarial fever as 15 gr. of quinine, but to be much less depressing to the heart.

OXIDE OF ZINC IN THE SUMMER DIARRHŒA OF CHILDREN.

Dr. Koblasenko, writing in a Russian medical journal, states that he has found great advantage from the use of zinc oxide in the summer diarrhœa of children. In the locality where he is in practice there was recently a very virulent epidemic. The mortality amongst young childreu treated by ordinary methods was as high as 50 per cent., whilst that amongst those treated by means of zinc oxide was only 8 per cent. He gave the zinc in a mixture with ether and tincture of rhatany.

IRISH FISHERIES NEGLECTED.

BY J. LAWRENCE-HAMILTON, M.R.C.S.

No. VI.

THE neglect of Parliament to cultivate and develop the great natural fishing resources of Ireland is not only an unjustifiable, ignorant, wealth-wasting blunder, but is also a financial and political error demanding practical legislative interference. The United States Government devotes upwards of £70,000 a year to the improvement and increase of the fishing industries of America. The apathy and indifference of Parliament in matters concerning a healthy, abundant, cheap fish supply, and the interests of the fishermen of the United Kingdom, tend to make fish bad and extravagantly dear. It omits to have ready in case of foreign war and invasion the services of fishermen as a trained, disciplined reserve to our navy. The French still continue bounties to their fishermen to keep up the supply of seamen for the French navy.

Ireland has a sea-coast of 2337 miles, and inland waters covering 574,887 acres, which supply chiefly a few salmon and eels. Nevertheless Ireland, for home consumption, actually largely *imports cured* fish. Where Irish railways exist, their stations are generally distant from the harbours; the result is, much fish is spoiled, and the cost of distribution of that which is saved is much enhanced. Besides refrigerator stores on shore, Ireland requires dry-air refrigerator steamers for its export fish trade, and refrigerator barges and insulated covered barges for its inland navigable waters.

Sole-breeding in Irish inland waters.—The inland fisheries of Ireland, at a trifling primary outlay, should be made sources of national wealth and industry. Many of the Irish inland waters would answer admirably for breeding the sole, the female fish often supplying from 100,000 to 200,000 eggs at a time. The sole is justly considered the most digestible and palatable fish, and its flavour seems always acceptable. Unlike salmon, mackerel, whiting, eel, trout, cod, and other fish, including the herring, the palate even of the fastidious invalid does not get tired of the sole, which has also the merit of being cooked quickly and easily. I believe that, unless the sole is extensively artificially cultivated, within a comparatively short period it will become, as a food fish, extinct. For reasons hitherto undiscovered, its already limited geographical area of natural production is gradually decreasing. In the battle of life and struggle for existence the sole will slowly but surely die out unless largely reared and farmed by man. Sea-fish can thrive and breed in fresh water by gradual acclimatisation, if by degrees the proportions of saline matter be reduced to those of fresh water. Artificially cultivated in Irish inland fresh waters, soles, bled prior to the clotting of their blood, gutted, well washed in fresh flowing water, and then immediately hard frozen in dry cold air, could be profitably exported in colossal quantities to England, Europe, America, and elsewhere. The fashion of selecting the extra high-priced small or "club" sole, because just sufficient for one person's meal, is a mistake. Such small soles are not so palatable as larger, thicker, heavier, cheaper soles. The number of eggs derivable from a one-pound sole is much more than double that to be obtained from a half-pound sole. Probably the sturgeon would thrive in inland Irish waters. The American shad and alewife, both large herrings, which leave the sea to spawn in fresh water, should be experimentally introduced into Ireland.

Fish farming in Irish peat waters. — The pike, perch, bleak, tench, and bastard carp thrive marvellously well in number and size in peat waters. This is a further source of wealth, industry, and food for Ireland, whose almost universal peat moss litter makes an excellent packing material for dry-air frozen fish. In the agricultural model peat farms of Northern Germany, instead of straw, peat moss litter is used with financial advantage, profit, and economy. Experience shows that it agrees better than straw with horses and cattle, whose manure it absorbs without giving off any unpleasant smell of the stable.

Historical injustice to the Irish fisheries.—To prevent the Irish competing injuriously with the English fisheries, Parliament under Cromwell sent many Irish fishermen to Connaught, on the west coast of Ireland, or the coast farthest from England, and even expatriated other Irish fishermen to the West Indian Islands. No Irish were then allowed to leave their own harbours to fish, whilst the English were engaged fishing in Irish seas and waters.

Conclusion.—The development of the coast and inland fisheries of Ireland should be considered by Parliament as a national, economic, and industrial question outside the range and scope of all party feeling and sentiment.

RABIES.—The number of dogs in England officially reported during the week ending Oct. 19th as affected with rabies was five, against eight in the previous week. Of these four were killed, and one died. The distribution was as follows: London, two; Middlesex, two; and York (West Riding), one.

THE PARIS UNIVERSAL EXHIBITION OF 1889.

WE are now about to conclude the campaign we have undertaken in favour of the Paris Universal Exhibition. From the very first we felt that, in spite of the unfavourable view taken in some quarters, this exhibition would be one of the grandest manifestations in favour of peace and progress the world has ever seen.

Unfortunately, or perhaps we should say fortunately, the task was of so gigantic a nature that it could only in part be accomplished. We feel keenly that there have been many omissions, yet, considering the limits of time and space, it was scarcely practical to do more. Altogether we have published nearly a hundred columns sent by our special correspondent at the Paris Exhibition. Much as this may seem, it is but little when compared with the immensity of the Exhibition, and the variety and importance of the interests there represented. But when to the Exhibition we add the sixty-nine official international congresses, of which twenty-seven were of direct interest to the medical profession or the sanitary reformer, and the number of other congresses, which were often equally interesting though not officially patronised, it will be seen that the task of giving some account of the centennial celebrations assumed gigantic proportions. Early in April, more than a month before the Exhibition was open, our commissioner was on the spot, examining the works, and obtaining from the administration and the leading exhibitors some account of what was to be presented. Thus we were able to publish descriptions of some of the more important features of the Exhibition before its doors were opened to the public. This we did with all the more pleasure as it is always in the earlier efforts that assistance is most useful. The Exhibition, it was at once evident, would show what immense progress had been accomplished in France with respect to the practical question of domestic drainage. The exhibits of the town of Paris render these results manifest, and we gave at length, accompanied by illustrations, an account of the new police regulations, by which houses in Paris can now be drained according to the most recent and approved sanitary methods. Though these new laws have as yet only been applied in a very small number of houses, our correspondent was able in a most effective manner to refute the sinister rumours set afloat as to the unhealthy condition of Paris. To assertions made under the impulse of personal vexation he opposed the official statistics so carefully and scientifically collected by Dr. Bertillon, and demonstrated that not only was Paris free from a scarlet fever epidemic, but that the great capital enjoyed during the Exhibition better health than it had done previously.

Concerning the Exhibition itself, we pointed out what sanitary difficulties had to be overcome; that the accommodation would have been ample but for the fact that no one could possibly have foreseen the immense success likely to ensue. Thus it happened that at times the crowds altogether exceeded in number whatever provision had or could have been made for them. Nevertheless, the English drainage applied at the Exhibition has withstood this great strain with wonderful efficiency, and no serious nuisance has arisen. With regard to the building itself, taken in conjunction with the most attractive of features, the Eiffel Tower, we naturally pointed out the bearing on public health that this revolution in building represented. As iron and porcelain take the place of stone and wood, new sanitary problems arise. Iron and enamelled hardware are not absorbent, as wood, brick, and stone; but iron more readily conducts heat and cold, glazed porcelain is less porous, and new difficulties in the matter of warming and ventilating arise. The vexed problem relating to the porosity of walls calls, therefore, more urgently than ever for a satisfactory solution.

Apart from these general questions, the individual exhibits, especially those of the English section, received some notice at our hands, and we also sought to mention French and foreign objects that might interest the profession. If these criticisms were not more lengthy and exhaustive, this is due to the fact that our representative's attention was diverted by the numerous congresses to which we have already alluded. These great gatherings, where sometimes upwards of seven hundred delegates, representing more than thirty nationalities, met together and discussed for a full week the gravest problems of the day, gave promise of so much good work that we were anxious to lend them the fullest support and to be adequately represented. In this, we are assured, we have been eminently successful. Our representative attended nine international congresses, and his very lengthy descriptions of the more important among these have brought us many cordial acknowledgments from the organisers of the congresses. More than this, Mr. Adolphe Smith, who, as an orator, speaks equally well in French as in English, was on many occasions selected, not merely as the spokesman of the English delegates, but of a great number of other nationalities; and in their name as in our name was able to proclaim, in eloquent terms, that the researches of science tended to unite the peoples of the world. He urged many practical suggestions relating to public health, and proposed and carried important resolutions. But throughout he strove to show that in England there were ardent sympathisers with the humanitarian and civilising work which has been done at these congresses and at this great Exhibition. If, by the speeches of our representative, if, by the publicity given to the proceedings in THE LANCET, we have helped to cement the bonds of international friendship, to dissipate national prejudices, and to shed the light of science still farther and farther into the darkness of ignorance, it will not be in vain that we shall have participated in the Universal Exhibition of 1889.

In view of the large number of visitors of different nationalities who attended the Exhibition and the various congresses in connexion with it, we append a translation in French of the above article.

L'EXPOSITION UNIVERSELLE DE PARIS DE 1889.

NOUS devons conclure la campagne que nous avons entreprise en faveur de l'Exposition Universelle de Paris. Du premier abord, nous avions senti, malgré l'opinion défavorable qui prévalait dans certains cercles, que cette Exposition serait une des plus grandes manifestations que le monde ait jamais vues, en faveur de la paix et du progrès.

Malheureusement, ou peut-être devons-nous le dire fort heureusement, la tâche était si grande qu'une partie seulement de la besogne pouvait être accomplie. Nous sentons vivement qu'il y a eu de notre part plusieurs et de graves omissions; mais si l'on considère les limites du temps et de l'espace à notre disposition ce n'était guère pratique de chercher à faire plus. Nous avons publié presque cent colonnes de correspondance qui nous ont été adressées par le correspondant spécial que nous avons envoyé à l'Exposition de Paris. Cela paraît assez con-

Digitized by Google

sidérable, mais c'est très peu en comparaison de l'importance des intérêts représentés. En outre, si à l'Exposition nous ajoutons les soixante-neuf congrès internationaux officiels, dont vingt-sept intéressent soit la profession médicale ou les hygiénistes, et un nombre d'autres congrès qui souvent étaient également intéressants quoiqu'ils ne fussent pas officiellement honorés par le gouvernement, on verra que la tâche imposée, celle de donner une description des célébrations centenaires, a pris des proportions gigantesques.

De bonne heure, en avril et plus d'un mois avant l'ouverture de l'Exposition, notre correspondant et rédacteur spécial était sur le chantier, examinant les travaux et obtenant de l'administration et de quelques-uns des principaux exposants des renseignements sur ce que l'on allait faire. Ainsi nous avons réussi à publier des descriptions des objets et des choses caractéristiques et importantes de l'Exposition, avant que les portes ne fussent ouvertes au public. Nous avons fait cela avec d'autant plus de plaisir que c'est toujours le premier pas qui coûte et que le concours donné dans les débuts est le plus utile. L'Exposition, on pouvait le constater dès le premier jour, devait démontrer l'immense progrès accompli en France à propos de la question toute pratique du drainage domestique. Les objets exposés par la ville de Paris rendaient ces résultats manifestes, et nous avons donné avec des détails et des gravures à l'appui, une description des nouveaux procédés adoptés par la Préfecture de Police, d'après lesquels il est maintenant possible de drainer les maisons de Paris selon les méthodes les plus modernes et les plus approuvées de l'hygiène. Quoique ces nouveaux arrêtés n'aient été, jusqu'à ce jour, appliqués qu'à un très petit nombre de maisons, notre correspondant a pu néanmoins, et cela d'une manière très effective, refuter les rumeurs sinistres que l'on avait propagées au sujet de la condition insalubre de Paris. Aux assertions irréfléchies faites sous l'impulsion d'une vexation, il opposa les statistiques officielles groupées avec tant de soins et de science par M. le Dr. Bertillon et il démontra que non-seulement il n'y avait pas d'epidémie de scarlatine à Paris, mais que la grande ville jouissait pendant l'Exposition d'un état de santé meilleur que durant les mois correspondants des années précédentes.

Quant à l'Exposition elle-même, nous avons décrit les difficultés sanitaires qu'il fallait surmonter; et avons dit que les services sanitaires (cabinets, &c.) auraient suffi, si l'immensité du succès n'avait pas dépassé tout ce que l'on pouvait prévoir. Ainsi il s'est trouvé parfois que la foule a atteint des proportions comme nombre bien au-delà de ce que l'on pouvait imaginer et pour lequel il est possible de fournir les services nécessaires. Néanmoins, le *drainage* anglais appliqué à l'Exposition a résisté à cette épouvantable épreuve avec une facilité réellement surprenante et aucun désagrément sérieux ne s'est produit. Pour ce qui concerne la construction elle-même, y compris son monument le plus remarquable, la tour Eiffel, nous avons tout naturellement démontré l'influence sur la santé publique que cette révolution dans l'art de la construction doit produire. Puisque la porcelaine et le fer prennent la place de la pierre et du bois, de nouveaux problèmes d'hygiène se présentent. Le fer et les poteries émaillés ne sont pas aussi absorbants que le bois, la brique et la pierre. Mais le fer conduit plus rapidement la chaleur et le froid. La porcelaine émaillée est moins poreuse; ceci suscite de nouvelles difficultés à propos du chauffage et de la ventilation. Il est donc encore plus urgent que jamais de trouver une solution satisfaisante du problème de la porosité des murs.

Ces questions générales à part les expositions individuelles, spécialement celle de la section anglaise ont reçu quelques notices dans nos colonnes et nous avons aussi cherché à signaler les objets français et étrangers qui pouvaient intéresser notre profession. Si ces critiques ne furent pas plus longues et plus approfondies, cela provient du fait que les nombreux congrès dont nous venons de parler ont absorbé une grande partie du temps de notre correspondant.

Ces grandes conférences où, quelques fois, il y avait plus de sept cents délégués représentant environ trente nationalités, se réunissaient pour toute une semaine et l'on y discutait les plus graves problèmes du jour. Cela promettait de si bons résultats que nous fûmes désireux de concourir à l'œuvre et d'y être bien représentés. En ceci, on nous l'assure, nous avons amplement réussi. Notre correspondant prit part à neuf de ces congrès internationaux et les longs comptes-rendus qu'il nous a envoyés nous ont valu les sincères remerciements des organisateurs de ces congrès. Mieux que cela, M. Adolphe Smith, qui comme orateur parle le français avec la même facilité que l'anglais, a été choisi plusieurs fois comme le porte-voix, non-seulement des délégués anglais, mais de ceux d'un grand nombre d'autres nationalités. Pour eux comme pour nous, il a proclamé en termes éloquents que les recherches de la science devaient unir les peuples. Il fit plusieurs propositions pratiques ayant rapport à la santé publique, proposa et fit adopter des vœux importants. Mais, en toutes ces circonstances, il chercha à demontrer qu'en Angleterre il existait des sympathies ardentes envers l'œuvre humanitaire et civilisatrice accomplie à ces congrès et à cette grande l'Exposition. Si, par les discours de notre représentant, si, par la publicité donnée à tous ces efforts dans THE LANCET, nous avons aidé à cimenter les liens de l'amitié internationale, à dissiper les préjugés nationaux, et à propager les lumières de la science parmi les ténèbres de l'ignorance, nous n'aurons pas participé en vain à l'Exposition Universelle de 1889.

THE BREWERS' EXHIBITION.

THERE can be little doubt of the growing value of trades-exhibitions. They not only mark the progress which has been made, but indicate also further possible improvement; and by those not familiar with the technicalities of a trade which is being exhibited useful information may generally be gained. At the Brewers' Exhibition, held at the Agricultural Hall last week, besides the usual plant, machinery, appliances, &c., incidental to the preparation of beer, wines, and spirits, much was shown illustrating the enormous advances that have been made of late years in that rapidly increasing industry—mineral water manufacture. Then there were also the hundred and one minor, accessories of both industries, such as improved corks, stoppers, bottles, syphons, barrels, beer-raising apparatus, syrups, essences, chemicals, filters, &c., as well as many articles having a more remote bearing.

One of the most important and interesting exhibits, and one we think likely to influence the future of the trade, was the patented carbonating apparatus of Messrs. Farrow and Jackson. The process must be regarded as a distinct novelty, inasmuch as the inventors use natural carbonic acid gas, which is obtained from the mineral springs near the extinct Eifel volcano, close by the Rhine. The apparatus was noticed in our last issue, but a few additional remarks by way of description may not be out of place. The gas is pumped into wrought iron "tubes," about four feet high and six inches in diameter, at a pressure which does not exceed 1170lb. to the square inch, and at a temperature of 86° F., which allows a wide margin for climatic changes. The "tubes" are first officially tested to 3750lb., and of course the gas contained in them is in the liquid state. This gas may be delivered into a convenient reservoir at any reduced pressure by means of regulating valves. For ordinary aerated water making it is only necessary to connect the "tube" with a copper cylinder, lined inside with block tin, and about three-quarters part full of water. The cylinder placed on a rocking stand is rocked backwards and forwards for a minute or so, the water thus becoming thoroughly impregnated with the gas. The cylinder is then connected with a "counter-fountain," and the contents can be drawn off as desired, any flavouring essence or syrup that may be required being put into the glass or bottle. The whole apparatus will easily go under an ordinary counter. There was also shown a smaller apparatus, by which the ordinary "gasogene" may be charged in the same way. The inventors have also applied this method to the raising of beer. Thus, by allowing the pressure of gas to be exerted upon beer in a cask, the liquor is readily forced up to a tap on the counter. In this manner, not only are the inconveniences attending the beer-engine done away with, but the beer cannot become stale and flat. Objection, however, may be raised by some to the possible opposite extreme—excess of gas. Amongst other novel exhibits may be mentioned a new vent-peg by Kiln. The peg is hollow, and a stout rubber tube connects it with the tap. If there is sufficient pressure in the barrel of course the beer easily flows and the tap need only be turned a quarter

Digitized by Google

round. But when vent is required the tap is turned half way, which, by an ingenious contrivance, admits as much air as is just necessary to allow the liquor to run out, and by turning off the tap the vent is effectually shut off again. This ensures beer in good condition, even, it is stated, when the barrel is nearly empty.

Messrs. J. Lumley and Co. exhibit some very fine quality corks as well as syphons for aerated water, the fittings of which are made of pure tin, an important point because of the well-known action of carbonic acid upon many common and injurious metals. Many improvements in screw stoppers are also shown. Whittingham and Ramsey exhibit a stopper, having a lock stud made of pure lignum vitæ, which, when placed beneath the flange in the bottle neck, by a half turn makes the bottle air-tight. Then there is Shepherd's patent screw valve. The thread is on the outside of the bottle, so that the rubber presses against the top of the bottle, diminishing the possibility of exposure of the liquid to any substance but glass. The Telescope Tap Company exhibit their ingenious barrel tap. Crawford and Co. show a carbon enamel as an effectual means for cleansing musty casks, &c. A very neat and simple bottle wrapper is shown by J. Deaton, quick packing and non-liability of the contents to fracture are claimed for it. The well-known firm of Stevenson and Howell exhibit their soluble essences of ginger, lemon, &c., as do also Duckworth and Co., manufacturing chemists, of Manchester. Amongst the filters exhibited for which special claims are made may be mentioned Maignen's Filtre Rapide and the Hamburg Rapid Filter of Jensen and Co., Hamburg. Metallic capsules, manufactured by the London Metallic Capsule Company, form quite a pretty exhibit. Non-intoxicant ales, chief of which is one called "Anti-Burton," a fermented drink containing less than ½ per cent. proof spirit, are exhibited by Cox and Co. And, lastly, there are the drinks, neither of which is the result of brewing or artificial aeration—viz., "Distil Coffee Extract," prepared by Beare, Gosnall, and Fry, Bouillon Fleet, Bovril, and the Beef Bouillon of Brand of Mayfair.

CALENDAR OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

FROM the Calendar of this institution, which has just been published by the Council, it appears there are 1138 Fellows of the College (of whom 737 obtained the Fellowship by examination, 11 were elected as Members of twenty years' standing, and 2 are *ad eundem* Fellows), 17,170 Members, 866 Licentiates in Midwifery, and 676 Licentiates in Dental Surgery. The holders of the Diploma in Public Health (granted in conjunction with the Royal College of Physicians) number 29. During the past collegiate year 679 candidates presented themselves in Elementary Anatomy and Physiology, 478 of whom passed in both subjects, 79 in Elementary Anatomy, and 56 in Elementary Physiology, 66 candidates were referred in both subjects; 56 candidates presented themselves in Elementary Anatomy, 43 of whom passed; 98 candidates presented themselves in Elementary Physiology, of whom 73 passed. The examiners are appointed in conjunction with the Royal College of Physicians. The fees received from candidates for this examination amounted to £3937 10*s*, the examiners receiving in fees £559 5*s*. Of 879 candidates who presented themselves in Chemistry, 552 passed and 327 were referred. Of 804 candidates who presented themselves in Materia Medica, 493 passed and 301 failed. The examiners in Chemistry and Materia Medica are elected by the Royal College of Physicians.

The examiners in Anatomy and Physiology for the Second Examination are appointed in conjunction with the Royal College of Physicians; they have conducted the Primary Examination under the Old Regulations, as well as the Second Examination of the Examining Board. Nine hundred and seventy-three candidates presented themselves for examination in Anatomy; 582 passed and 391 were referred; and 1069 candidates presented themselves in Physiology, of whom 579 passed and 490 were referred. The fees received for these examinations from candidates amounted to £5014 16*s*., the examiners receiving in fees £1972 5*s*.

The Board of Examiners in Anatomy and Physiology for the diploma of Fellow, elected by the Council from the Fellows of the College, held during the past year two examinations, and 179 candidates presented themselves, of whom 73 passed and 106 were rejected. The fees received amounted to £1176, and the fees to the Board to £805 10*s*.

The Court of Examiners, elected by the Council from the Fellows of the College, conduct the Third or Final Examination in "Surgery" of the Examining Board, as well as the Pass or Final Examination under the Old Regulations and the Pass or Final Examination for the Fellowship. During the year the Court has held two examinations for the Fellowship, and four for the Membership; at the former there were 83 candidates, 48 of whom passed and 35 were referred. For the Membership 864 presented themselves, of whom 476 passed and 388 were referred. The fees paid by candidates amounted to £10,133 18*s*., and the fees paid to the Court of Examiners and the Examiners in Midwifery amounted to £5513 17*s*. The Examiners in Medicine under the Scheme for an Examining Board in England are elected by the Royal College of Physicians; of 466 candidates who presented themselves for this examination during the year, 334 passed and 132 were referred. The Examiners in Midwifery under the Scheme are elected in conjunction with the Royal College of Physicians, and have examined 541 candidates, of whom 365 passed and 176 were referred.

The Board of Examiners in Dental Surgery has held two meetings for the examination of 48 candidates, 31 of whom received the diploma. The fees paid by them amounted to £325 10*s*., the Board receiving £151 4*s*.

With regard to the finances of the College, it appears that the income from all sources amounted to £121,337 14*s*. 5*d*., derived principally from sale of stock—viz., £87,462 1*s*. 3*d*.—the next largest receipt being, as already shown, from fees paid by candidates for the diplomas of the College—viz., £20,587 14*s*.; rents from chambers adjoining the College, £1360 15*s*.; investments, £5696 13*s*. 9*d*.; trust funds, £273 7*s*. 7*d*.; incidental receipts, public health examination, hire of rooms, fees from Council, &c., £558 6*s*. 11*d*.; fees retained for candidates, £933 5*s*.

The expenditure for the year amounted to £121,166 13*s*. 6*d*., leaving a balance at the bankers' of £171 0*s*. 11*d*., the largest item being £83,892 1*s*. 6*d*., for purchase of stock, the next largest amount being for fees paid to examiners—viz., £8902 1*s*.; extension of College premises, £6861 15*s*. 4*d*.; Savoy estate (half outlay), extension of Examination Hall, £4200; salaries, wages, and pensions for officers and servants in the three departments, museum, library, and office, amount to £5219 3*s*. 6*d*.; fees to Council, £302 8*s*.; rates, taxes, and insurance absorb the sum of £1126 10*s*. 6*d*.; extraordinary expenditure—i.e., Hunterian Festival, conversazione, furniture, &c.—£1326 0*s*. 8*d*.; fees returned to candidates, £1051 5*s*.; half general working expenses of Examination Hall, £4260 11*s*. 7*d*. Under miscellaneous items, alterations and repairs, fuel, light, trust funds, lectures, &c., about £4000 appears to have been expended.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN twenty-eight of the largest English towns 5801 births and 3204 deaths were registered during the week ending Oct. 26th. The annual rate of mortality in these towns, which had been 17·5 and 18·7 per 1000 in the preceding two weeks, declined again last week to 17·5. During the first four weeks of the current quarter the death-rate in these towns averaged 17·3 per 1000, and was 2·3 below the mean rate in the corresponding periods of the ten years 1879-88. The lowest rates in these towns last week were 9·7 in Birkenhead, 10·5 in Norwich, 11·7 in Derby, and 11·8 in Portsmouth. The rates in the other towns ranged upwards to 24·0 in Manchester, 27·6 in Newcastle-upon-Tyne, 28·0 in Plymouth, and 29·0 in Preston. The deaths referred to the principal zymotic diseases, which had been 352 and 414 in the preceding two weeks, declined again last week to 356; they included 83 from scarlet fever, 60 from diarrhœa, 58 from "fever" (principally enteric), 54 from whooping-cough, 53 from diphtheria, 48 from measles, and not one from small-pox. These zymotic diseases caused the lowest death-rates in Leicester and Wolverhampton, and the highest rates in Sunderland, Preston, and

Digitized by Google

Plymouth. The greatest mortality from scarlet fever occurred in Liverpool and Plymouth; from diarrhœa in Norwich and Preston; from whooping-cough in Preston; from measles in Preston, Newcastle-upon-Tyne, and Sunderland; and from "fever" in Nottingham and Halifax. The deaths from diphtheria included 37 in London, 3 in Salford, and 2 in Cardiff. Small-pox caused no death in any of the twenty-eight great towns; and no small-pox patient was under treatment at the end of the week either in the Metropolitan Asylum Hospitals or in the Highgate Small-pox Hospital. The number of scarlet-fever patients in the Metropolitan Asylum and the London Fever Hospitals at the end of the week was 1450, against numbers increasing in the preceding seventeen weeks from 559 to 1394; 182 cases were admitted to these hospitals during the week, against 177 and 188 in the previous two weeks. The deaths referred to diseases of the respiratory organs in London, which had increased in the preceding five weeks from 142 to 300, declined again last week to 281, and were 125 below the corrected average. The causes of 75, or 2·3 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Hull, Nottingham, Portsmouth, and in four other smaller towns; the largest proportions of uncertified deaths were registered in Halifax, Leicester, Blackburn, and Bolton.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 18·3 and 20·5 per 1000 in the preceding two weeks, declined again to 19·3 in the week ending Oct. 26th; this rate exceeded by 1·8 the rate that prevailed during the same week in the twenty-eight large English towns. The rates in the Scotch towns ranged from 14·1 and 15·4 in Paisley and Edinburgh to 22·2 in Perth and 23·2 in Glasgow. The 494 deaths in the eight towns showed a decline of 30 from the number in the previous week, and included 13 which were referred to diphtheria, 12 to diarrhœa, 10 to whooping-cough, 9 to measles, 6 to "fever" (typhus, enteric, or ill-defined), 6 to scarlet fever, and not one to small-pox; in all, 56 deaths resulted from these principal zymotic diseases, against numbers declining in the four previous weeks from 74 to 61. These 56 deaths were equal to an annual rate of 2·2 per 1000, which exceeded by 0·3 the mean rate last week from the same diseases in the twenty-eight English towns. The deaths referred to diphtheria, which had been 13 and 6 in the previous two weeks, rose again last week to 13, of which 6 occurred in Glasgow, 3 in Edinburgh, and 2 in Leith. The 12 deaths attributed to diarrhœa showed a further decline from recent weekly numbers, and included 5 in Glasgow, 3 in Dundee, and 2 in Greenock. The 10 fatal cases of whooping-cough were also fewer than in any recent week; 5 were returned in Edinburgh and 4 in Glasgow. The deaths from measles, which had been 7 and 9 in the previous two weeks, were again 9 last week, and included 3 in Aberdeen, 3 in Leith, and 2 in Edinburgh. The 6 deaths referred to "fever," of which 4 occurred in Glasgow and 2 in Aberdeen, showed a decline of 5 from the number in the previous week. Two of the 6 deaths from scarlet fever were returned in Glasgow. The deaths referred to acute diseases of the respiratory organs in the eight towns, which had been 87 and 118 in the preceding two weeks, further rose last week to 122, and were 1 above the number in the corresponding week of last year. The causes of 67, or nearly 14 per cent., of the deaths registered in the eight towns were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 23·2 and 26·5 per 1000 in the preceding two weeks, declined to 21·0 in the week ending Oct. 26th. During the first four weeks of the current quarter the death-rate in the city averaged 24·2 per 1000, the mean rate during the same period being 16·3 in London and 17·1 in Edinburgh. The 142 deaths in Dublin showed a decline of 37 from the number in the previous week; they included 9 which were referred to diarrhœa, 6 to "fever," 1 to measles, 1 to diphtheria, 1 to whooping-cough, and not one either to small-pox, or scarlet fever. Thus the deaths from these principal zymotic diseases, which had been 23 and 19 in the two previous weeks, further declined last week to 18; they were equal to an annual rate of 2·7 per 1000, the rate from the same diseases being 1·7 in London and 2·3 in Edinburgh. The 9 deaths attributed to diarrhœa exceeded the number in the previous week by 3; while the deaths referred to "fever," which had been 7 and 10 in the preceding two weeks declined again last week to 6. The deaths of infants showed an increase of 6 upon the number in the previous week, while those of elderly persons showed a decline of 17. Five inquest cases and 4 deaths from violence were registered; and 41, or considerably more than a quarter, of the deaths occurred in public institutions. The causes of 16, or more than 11 per cent., of the deaths in the city were not certified.

"Audi alteram partem."

ON THE APPLICATION OF ICE TO THE CHEST IN HÆMOPTYSIS.

To the Editors of THE LANCET.

SIRS,—In the discussion which followed the reading of Sir Andrew Clark's paper on the "Hæmoptysis of Elderly Persons" before the Medical Society, Dr. Quain strongly condemned the practice of applying ice to the chest wall, saying that it did no good, but rather harm, by inducing bronchitis. This statement, coming from so high an authority, seems to me worthy of consideration. As a rule, when called to a case of blood spitting we find ice in bags or bladders lying upon the patient's chest. The practice is a routine one, and appears to commend itself to both the profession and the public. For my own part, I look with increasing distrust on the *prolonged* application of ice as a means of arresting pulmonary hæmorrhage. Many years ago I was with a gentleman who had recurring hæmoptysis very severely, and down his back was hanging a bag full of ice. After some time for observation, I remarked to his wife that I believed the ice-bag was doing no good, but possibly harm, and I removed it. After its removal we got on better, the bleeding ceased, and the man is alive and well now. It appears to me that the *sudden shock* of the ice at first contracts the vessels and may do good, but its continuous application does not maintain this contraction, but is very likely to cause congestion and bronchitis. The late Dr. Gooch, in his works on Midwifery, relates how he was called to a lady nearly dead from hæmorrhage, and whose abdomen was covered over with ice. He says: "I swept all the ice away, and from a height I poured a douche of cold water suddenly on the abdomen, with the effect of immediately arresting the bleeding." Again, as was suggested by the President of the Medical Society, if I caught his words correctly, ice over the heart may slow that organ, and so help to arrest a flow of blood. Dr. Walshe[1] says he has seen the *cautious* application of ice to the spine and over the heart repeatedly almost instantaneously arrest the flow of blood. My own practice has been to try the sudden application of ice, but, as a matter of experience, I have learned to distrust the prolonged and continuous contact of ice with the chest or back as a means of stopping a blood spitting. Dr. Lauder Brunton[2] has found that when ice is applied to the abdomen of an animal the mucous membrane of the trachea and larynx becomes in half a minute deadly pale from contraction of the vessels. Though the ice is allowed to remain on the abdomen, the tracheal mucous membrane quickly changes colour, and to the paleness succeeds, first, slight redness, then deep congestion, and in ten minutes lividity. These observations appear to me to show how prolonged application of ice may, as Dr. Quain said, prove a powerful inducer of bronchitis.

I am, Sirs, yours obediently,

JOHN C. THOROWGOOD, M.D., F.R.C.P.,
Physician to the City of London Hospital
Welbeck-street, W., Oct., 1889. for Diseases of the Chest.

To the Editors of THE LANCET.

SIRS,—I have read with much interest the able and suggestive remarks on arthritic hæmoptysis by Sir Andrew Clark, Bart., which appeared in your last number. With your permission I should like to mention a case of pul-

[1] Diseases of the Lungs, p. 408.
[2] Page 252 of his Pharmacology and Therapeutics.

Digitized by Google

monary hæmorrhage which has come under my observation, and which seems to be confirmatory of the views put forth by this distinguished physician. Several years ago I was summoned to attend a gentleman, about eighty years old, who, after having had a sail in an open boat during an easterly wind, was suddenly seized with copious hæmoptysis, associated with bronchitic symptoms. There was no evidence of cardiac disease, of thoracic aneurysm, or of tuberculosis. As the breathing was considerably embarrassed saline aperients with diaphoretics were prescribed. At my next visit the following day I was agreeably surprised to find the hæmorrhage had entirely ceased, but that an acute attack of gout had supervened in the right foot. Under the usual alkaline treatment the podagra speedily disappeared, the recovery being complete. Does not this case supply the *experimentum crucis* necessary to establish the correctness of Sir Andrew Clark's view? Was it not clearly one of gouty hæmoptysis due to thrombosis of the terminal blood-vessels of the lung? Your insertion of these few lines will oblige your obedient servant,

Weymouth, Oct. 28th, 1889. JOHN MOORHEAD, M.D.

ST. MUNGO'S COLLEGE, GLASGOW.

To the Editors of THE LANCET.

SIRS,—Principal Blackie says that I am wrong in my facts, which I could easily have ascertained from the secretary of the College or himself, with both of whom I am well acquainted. It is not quite so easy to get at the facts as Dr. Blackie avers. In this matter he knows well enough that I would not trouble him for private information; and on applying two days ago to the secretary (with whom, by the way, I have no acquaintance at all) for information in verification of the Principal's letter, I was put off, as I fully expected, with the usual official formula about consulting the governors. Were I inclined to be critical, I might point out that Dr. Blackie's statement that the Committee reported to the governors does not traverse mine that the latter did not ratify; but I let that pass. Other questions hang round this alleged ratification. Was it legally valid? One of the governors present at the meeting informs me that, to the best of his recollection, there were only four present, including himself. This would involve legal invalidity. But, assuming that this gentleman's memory is at fault, as it probably is, and that the appointments are legally valid, what were the moral weight and significance of this ratification of the meeting of August 6th? Will the Principal inform me that the circular calling the meeting contained any intimation that the board would be asked that day to exercise the most important of its functions and elect the entire staff? That there would be a clear departure from the clause in the memorandum of association regarding the absorption of the Royal Infirmary Medical School? That new chairs unknown in that school were to be founded and filled? That the "Academic Committee" had so far departed from the usages—I might say the decencies—of reporting committees as to nominate one of their own number to fill one of the new chairs? I venture to say, Sirs, if a hint of these things had come to the ears of the governors, instead of this mere handful of members, barely, if indeed actually, forming a legal quorum, and not amounting to one-fifth of the entire body of governors, there would have been a very different meeting. There would have been a meeting whose decisions would have carried moral weight, and whose method of appointments could not have been impugned by virtually the entire voice of the medical profession of Glasgow as these have been, even by several of those gentlemen who have received them.

I am, Sirs, yours faithfully,

Glasgow, Oct. 29th, 1889. J. WALLACE ANDERSON.

THE PRACTICAL ELEMENT IN MEDICAL EDUCATION.

To the Editors of THE LANCET.

SIRS,—I did not immediately reply to Dr. Gairdner's letter in THE LANCET of Oct. 19th, as up to that time Dr. Clifford Allbutt had remained silent, and I am anxious not to waste the valuable space you so generously place at my disposal. Now that I have both letters before me, I need only ask for very few lines, and these, I feel sure, you will give me. Dr. Gairdner's answer is, as I fully expected it would be, a simple plea for thoroughness in clinical work. After careful consideration of the position he takes up, I am satisfied that he and I do not, in reality, differ in principle. He pleads for one thing, and one thing only—viz., *thoroughness* in all the work the student does. *And so do I.* But Dr. Gairdner appears to me to forget, or to ignore, the necessity for this very principle so far *as preparation for student life* is concerned. And, as Dr. Clifford Allbutt admits that he had not really read my address, and was speaking on only vague recollection of what he believed my opinions to be, I can well afford to rest content with his explanation. Of one thing I was quite certain—that he would not wilfully misrepresent me; and though I may regret that, speaking on so important an occasion as the opening of St. George's School, he should have spoken under mistaken impressions, I am quite content to accept his explanation. Our friendship is too old and too sincere to admit of any other course. At the same time, speaking, as I did in my address, not only as a member of the General Medical Council, but of its Educational Committee, he might have felt sure that I should have weighed seriously every word I wrote. He too appeals for thoroughness of work, and so does everyone else who has taken part in the discussion so far; but I maintain that I make the same appeal much more thoroughly than does either Dr. Gairdner or Dr. Clifford Allbutt, for I seek first to build upon a good foundation, well and solidly laid, and to raise upon that an enduring superstructure. To obtain this I cannot believe that it can be safe or scientific first to build your house, however substantially, and then to seek to put in your foundations afterwards. I have also carefully and thoughtfully read each of the other letters that have appeared in your columns upon the subject, and I am grateful to those who have written them. Some seem to me to hit the right nail on the head, but others are already beginning to wander from the point in question. Therefore, with a view to keep the discussion on strictly correct lines, I venture to restate the items of the programme I propound: (1) A sound preliminary education carefully and satisfactorily tested before registration; (2) a short preparatory pupilage of *one*, or, under very favourable circumstances, of even *two* years, with either a certificated practitioner or at a public institution; (3) a curriculum of four years, devoted to scientific and clinical study, to be spent at a medical school and hospital, or, when possible, at a university. I am, Sirs, yours truly,

Leeds, Oct. 28th, 1889. C. G. WHEELHOUSE.

HOSPITAL OUT-PATIENT REFORM AND A PUBLIC MEDICAL SERVICE.

To the Editors of THE LANCET.

SIRS,—Medical practitioners should feel greatly obliged to you for your practical editorial remarks in your issue of Oct. 19th. The points at issue are by no means difficult of solution. The two chief matters to note are these: First, that a genuine reform of the out-patient departments of hospitals and of dispensaries must of sheer necessity take place; and, second, that some scheme must be worked by which the wage-earning classes may be able to provide themselves with efficient medical, surgical, obstetric, and dental treatment, and medicines. We are all agreed on these two items. Next I propose that a wage-earner making up to 20*s.* a week, or a wage-earner and family making up to 25*s.*, should be eligible persons for free medical relief, and should have a right, if they so wish, to demand it, just as they have a right to plead destitution to the Poor-law, and so compel them to gain relief. I think no one can say this limit is too low. Next I propose that a Public Medical Service should be formed, and that wage-earners making up to £2 5*s.* per week should be eligible. Those making above that should be able to provide for themselves. The patients of the Public Medical Service could provide for themselves either by making small *immediate* payments, or by insuring under the provident dispensary plan. May I point out that my scheme *does* provide for the visiting of patients at their homes. As to making separate charges for medicines, I fear we must do so. There is no earthly good in our trying to ruin the chemists; we would only make them our bitterest enemies. Besides, I feel certain that the prescribing can be done as cheaply at the chemist's as by a service which will have to pay for drugs, bottles, &c., and the salary of a dispenser. However, these are matters of detail. But do not let us draw up any scheme which will make us prescribe large quantities of coloured water and

Digitized by Google

cease from using genuine drugs. If the doctors of a Public Medical Service wish to charge one fee and then to make some arrangement with local chemists to dispense each prescription at, say, 4*d.* each, they can do so; but then the fee would require to be raised. It has been suggested to me by a chemist that he should provide the medicines at the Public Medical Service and send his assistant to dispense two hours each day, and charge a certain sum to the doctor. Such a plan would be a good one, but then it would exclude all the other neighbouring chemists.

As to your remarks about doctors holding hospital appointments, I can only say I fear they will not give much help. It has been said to me that there are not fifty medical practitioners in England whose mouths could not be closed by the mere promise of a hospital appointment. It is a money-making thing to be on a hospital staff. If only we doctors could find out that in the long run honesty is, even as a policy, the best, surely we would cease being so dishonest. I do not take the high level of preaching honesty as a virtue, but only, so low down, as a mere matter of policy. Our predecessors at the College of Physicians, London, drew up, and carried out, this bye-law: "No Fellow or Member of the College shall officiously, *or under colour of a benevolent purpose*, offer medical aid to or prescribe for any patient whom he knows to be under the care of another legally qualified practitioner." Might we not, as honest and honourable men, both in hospital practice and in private life, try to carry out this good old rule? Bickering, backbiting, and other forms of "professional meanness" would thus be reduced to a minimum. In the meantime, let us try to improve our position, and cease to train up about half of the community to depend on the charity of others.

I am, Sirs, yours faithfully,

Liverpool, Oct., 1889. ROBERT REID RENTOUL, M.D.

*** We have thought it advisable to omit a sentence or two from the above letter—an omission, however, which does not at all affect the coherency of the argument intended to be advanced.—ED. L.

THE PRESYSTOLIC MURMUR.

To the Editors of THE LANCET.

SIRS,—I have read with much interest Dr. Howship Dickinson's lecture on the "So-called Presystolic Murmur." Dr. Dickinson appeals to the rising generation to throw over the orthodox presystolic theory. He will, I venture to think, not do so in vain. I for one, a young member of the profession, have never been able, with the most careful and patient study of cases of mitral disease, to detect a presystolic murmur—i.e., a murmur distinct from, and prior in point of time to, the first cardiac sound. If the so-called presystolic murmur is an obstructive murmur, then in a case of double mitral disease one ought to hear three murmurs: (1) presystolic; (2) systolic; (3) diastolic. I have never heard more than two, systolic and diastolic. Dr. John Harley used to teach that there is no such thing as a presystolic murmur—in other words, that a presystolic is a systolic as regards time, and is regurgitant; and I have never been able to disagree with him yet. I have little doubt but that his teaching on the subject is the same to-day as a few years ago, for, to use Dr. Dickinson's words, "old views, like old tissues, get indurated."

I am, Sirs, yours faithfully,

Nottingham, Oct. 26th, 1889. A. J. HELM MONTAGUE, M.D.

HYOSCINE AS A SEDATIVE.

To the Editors of THE LANCET.

SIRS,—Believing that negative results, especially in the case of a comparatively new drug, are as worthy of publication as positive results, I venture to give my experience of hyoscine as a hypnotic and sedative, and to say at once that that experience has been entirely unfavourable. In February, 1888, having read in THE LANCET (Feb. 4th, 1888) the very favourable results obtained by Dr. Thompson, I immediately obtained some of the hydro-bromate of hyoscine from the source there mentioned, and with considerable hope made use of it. Among several other cases I remember distinctly two cases in which I gave the drug. The first was a case of melancholia in a man rather above middle age, with great restlessness and sleeplessness at night. The hyoscine had not the slightest effect in quieting this patient, but rather the reverse, as after it he expressed himself as absolutely afraid to have a second dose, lest, as he said, it should quite drive him out of his mind. The second case was one of paralysis agitans, accompanied by great sleeplessness at night. In this case, too, the hyoscine entirely failed; whereas afterwards the tincture of hyoscyamus, as recommended by Charcot, had a most marked effect in producing sleep for a time. Subsequently I used the hyoscine as a general hypnotic in the wards for some time, but found it so uncertain that although I still have a little of the drug in hand, I have never since prescribed it.

I am, Sirs, yours faithfully,

Southport Infirmary, Oct. 29th, 1889. JOHN J. WEAVER.

"MEAN DURATION OF LIFE."

To the Editors of THE LANCET.

SIRS,—In your annotation last Saturday, under the heading of "Mean Duration of Life in London," you made some remarks on my last annual report for the parish of St. George, Hanover-square, in which you say that I use the term "mean duration of life" in an incorrect sense. After some preliminary observations, the writer of the article says: "It is not difficult to guess that mean duration of life is here used to describe the mean age of the persons dying in these registration sub-districts during last year." I need only say that the *guess* is a bad one, as I meant what I said—"mean duration of life," and not "mean age at death." "Dr. Corfield's fallacy" exists only in the brain of the writer of the article.

I remain, Sirs, yours faithfully,

Savile-row, W., Oct. 29th, 1889. W. H. CORFIELD.

*** Dr. Corfield here states that the term "mean duration of life" used by him does not signify "mean age at death," and leaves it to be inferred that he used the term in its correct signification, implying that he has calculated life tables for Belgravia and Mayfair sub-districts, not only for 1888, but also for 1875, to say nothing of similar London life tables for 1878 and 1888. With regard to the results obtained by Dr. Corfield's method, whatever it may be, we would like to remind him that the "mean duration of life" shown by life tables based upon selected healthy districts, and upon upper class, clergy, and peerage experience, only ranges between forty-nine and fifty-three years. It follows, therefore, that Dr. Corfield's "mean duration" of 73·6 years for the mixed population of Mayfair is phenomenal, to say the least of it, and its excess of 11·3 years upon the "mean duration" of Belgravia is entirely incomprehensible.—ED. L.

THE "EARLY DIASTOLIC MURMUR."

To the Editors of THE LANCET.

SIRS,—May I be allowed to correct a statement made on p. 844 of THE LANCET of Oct. 26th, with reference to the interpretation which I am alleged to have given of the so-called "early diastolic murmur" of mitral stenosis? The murmur which I have interpreted as a murmur of pulmonary regurgitation—"the murmur of high pressure in the pulmonary artery"—I have been careful to distinguish from the early diastolic mitral murmur, the existence of which I fully recognise. The two murmurs may exist together in the same case, but are easily distinguished, as they differ in quality and localisation.

I am, Sirs, your obedient servant,

Manchester, Oct. 30th, 1889. GRAHAM STEELL.

THE NOTIFICATION OF INFECTIOUS DISEASES ACT.

To the Editors of THE LANCET.

SIRS,—Now that notification of infectious disease is about to become general, why should a strong effort not be made to include venereal diseases in the list? This disease, in its protean forms, claims more victims every year, and is more disastrous and far-reaching in its dire effects, than all the other notifiable diseases put together. The public would soon realise their danger, and take the necessary steps to stamp it out.—I am, Sirs, yours faithfully,

West Hartlepool, Oct. 26th, 1889. S. GOURLEY.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Out-patients at the Infirmary.

IN common with other parts of the country attention has been directed here to the increase in the numbers of patients applying for medical treatment in the out-patient department of the infirmary, and a special committee was appointed to consider the whole question of administration in that department. At the monthly meeting of the board held on Monday this committee reported that the increase was by no means so large as was supposed. It had been suggested that a small charge should be made for medicines supplied, and that some restrictions should be placed upon patients coming from adjacent towns; but in the end the committee recommended that no change was at present necessary in the out-patient department beyond some increased vigilance being exercised in the quantity of medicine supplied, which appears to have been hitherto on a lavish scale.

The Infirmary and its Fever Hospital.

A fortnight ago a special meeting of the Infirmary Board was held, to consider an important question in connexion with the Fever Hospital. A communication had been received from the Salford Corporation asking if arrangements could not be made for the reception and treatment of all fever patients from Salford at the Monsall Hospital, and thus save the Salford Corporation from the necessity of building a new hospital to replace the one in Cross-lane, which is at present overcrowded, and must shortly come down to make way for railway requirements. It was pointed out that large sums of money (some £30,000 or more) had been left in trust to the infirmary for the special purposes of providing fever wards for Manchester and the district, and Salford claims to have some right to a part of this provision. The Fever Hospital Committee were divided on the question of the desirability of complying with Salford's request, and left the matter for the Board, which is the supreme governing body of the institution, to decide. After a long discussion it was resolved by seven votes to five to decline to receive the patients from Salford. Judging, however, from the tone of the discussion at the meeting, and from what is generally said upon the subject, the time is not far distant when the infirmary will take steps to relieve itself entirely of the responsibility of maintaining a large hospital for infectious disease, and hand it over to those whose duty it is to provide isolation for infectious cases and to deal with outbreaks of epidemic disease—i.e., the Health Committee of the Corporation. Looking at the question from a purely financial point of view, it is surprising that the corporation has been content to go on so long paying enormous sums of money annually, out of which the infirmary makes considerable profit. Taking the past three years only, the fever hospital accounts show an excess of income over ordinary expenditure of nearly £14,000. In the meantime Salford is at its wit's end to provide accommodation for the large number of cases of scarlet fever and diphtheria at present occurring in the borough, and has at last decided to delay no longer in taking steps to provide itself with a hospital of its own, with ample accommodation for all possible requirements, small-pox excepted, which disease is still to be treated at the Infirmary Fever Hospital.

The Southern Hospital.

At the annual meeting of this charity a record of increased work and increased expenditure was the chief feature. The maternity department has much developed during the last few years. In the twelve months covered by the report, 782 midwifery cases had been attended at the patients' own homes and 86 had been received into the wards of the hospital. The weak feature of the report was the falling off in the annual subscriptions, and, although happily during the year the institution had had a considerable increase in donations, this source of income is always fluctuating and a precarious one to depend upon for maintenance.

Owens College.

The number of entries in the medical department bids fair to maintain, if not to exceed, that of the last few years. At the time of writing 105 entries have been made, of which 75 are first year's men, and 32 are partial entries. There are also more than 50 entries in the preliminary scientific course. The Combe Lectures by Professor Sterling, of which two have at present been delivered, are being well attended; the first dealt in a general manner with all the sense organs, the second with the special sense of vision. The lectures are made attractive with a series of interesting experiments and exhibits. The annual dinner of the associates of the College takes place to-morrow week.

Sir H. Roscoe and Rabies.

One of our local members of Parliament and late professor in the college, Sir Henry Roscoe, is giving considerable satisfaction to many of his constituents by his advocacy of the Pasteurian treatment in dealing with rabies. Recently he delivered a lecture on the subject at Birmingham, and last week he was again to the fore at a meeting held in St. James's Hall, London, to promote measures for the extinction of hydrophobia in this country.

October 29th.

NORTHERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENT.)

Death of Mr. Mordey Douglas, M.R.C.S., of Sunderland.

I REGRET to notice the death in Sunderland, at the residence of Mr. Samuel Story, M.P., on Sunday last, of Mr. Mordey Douglas, a well-known practitioner of that town. Mr. Douglas had been in delicate health for several years, and for some time he was compelled by his weak chest to spend his winters in the Canary Islands, where he had established at Las Palmas an institution for invalids. As well as being an active public man, Mr. Douglas was an energetic practitioner. He was one of the originators of the Children's Hospital in Sunderland, and for some time was medical officer of health for the Port and Borough of Sunderland, taking a very prominent part, until he resigned these offices, in all matters relating to sanitation. He was a bold and good operator, and about seventeen years ago extirpated the whole tongue by the galvanic écraseur. I remember seeing the case at the Northumberland and Durham Medical Society, and it was considered by those present to be a most complete and satisfactory operation. This was at a time when operations on the tongue were not so fully undertaken as now. Mr. Douglas, who was only forty-eight years of age, has left a widow, two daughters, and a son at Las Palmas to mourn their loss. As well as being attended by his friends in Sunderland, he was also seen in his last illness by Dr. Drummond of Newcastle. It may be mentioned that Mr. Douglas was a nephew of the celebrated Dr. Mordey, J.P. and Mayor of Sunderland, whose services in connexion with the first outbreak of cholera in this country at Sunderland brought him the offer of knighthood from William IV., together with the appointment of Surgeon Extraordinary to his Majesty, both of which honours he, however, declined.

Sunderland and North Durham Eye Infirmary.

The committee in their report state that the infirmary has now been in existence for fifty-three years, and is treating 1000 new cases yearly. Its accommodation for in-door patients is, however, very limited and inadequate, and they are about to consider the building of a new wing, costing with site £5000, and appeal for help, which should be forthcoming in a large and prosperous town like Sunderland.

Ambulance Work in the North.

At a public meeting held last week in connexion with the Bedlington colliery ambulance and science classes, at which Sir Matthew White Ridley spoke and Lady Ridley presented prizes, it was mentioned that of the 1600 or 1700 men employed at this large mine, about one in every four had received ambulance instruction. As to the ladies' classes, Surgeon-Major Hutton reported: "He had seen many classes of ladies in all positions in life, and he thought few of them had been better up than the ladies' class at the Bedlington colliery."

Bradford Water-supply.

It is stated in the local papers that the Bradford Corporation have set on foot a scheme of a most elaborate character, by which it is hoped to obtain a better water-supply than at present exists. The scheme propagated by the Bradford

Digitized by Google

Town Council, and for the carrying out of which a Bill has been framed to come before the proper authorities, proposes to replenish the reservoirs connected with the town of Bradford by the water from the Nidd above Pateley Bridge. The Knaresborough folk, who gain their water-supply from the Nidd, which flows past that town, are naturally up in arms against any such scheme as that propounded by the Bradford people, and as both York and Knaresborough have in Bradford a common foe as far as this scheme of water-supply is concerned, a conference of the two former towns has taken place, and conditions have been suggested by which a modification of the Bradford scheme may be rendered harmless to the users of the Nidd water in the lower Yorkshire towns and districts.

Newcastle-on-Tyne, Oct. 29th.

EDINBURGH.

(FROM OUR OWN CORRESPONDENT.)

The Royal Medical Society.

ON Friday last, Professor Sir Douglas Maclagan gave the opening address of the 153rd session of the Royal Medical Society. Dr. H. H. Littlejohn occupied the chair. The address was characteristic of the speaker. It gave evidence that his views had advanced with advancing medical science, but that he still held to what was good in the practice of his earlier years. Taking as his subject venesection, Sir Douglas maintained that the disuse of the lancet was due to the advance which had been made in medical science during recent years. There might have been some change in the type of disease, though he was scarcely prepared to state that this had been proved, but he thought that we must acknowledge some change in the type of our patients. We were all living and working at a higher pressure than formerly, and he thought that in consequence of this the manifestation of the diseases that attacked us were somewhat different from those of fifty years ago, so that the change of type was not so much in the disease as in the patient. With all this, let them remember that their forefathers had the authority of centuries to shake off, and that, though they did use the lancet rather needlessly, they should not be blamed indiscriminately. Let the practitioners of the present day recognise in all humility the advantages which they enjoyed through the progress of medical science. He summed up by stating that they had to mark: (1) the wonderful change which had taken place in therapeutics as illustrated by the disuse of blood-letting, chiefly within his own professional lifetime; (2) that they believed that, as regards this therapeutical method, they had wiser and better views than the best practitioners of the former age had; and (3) that this improvement in practice was due to the superior wisdom or skill of this age. Not the least interesting part of the address was that in which was described an interview that he and Dr. Allen Thomson had with, among others, Goethe, at Weimar, about eight months before the death of the great poet and man of science, who was at that time eighty-two years of age, but still loved to have intercourse with younger men. He took an interest in all their studies and in the reports that they brought of Scotch science and English literature, and thus left upon them an impression which could never be obliterated. They would pardon him, said Sir Douglas, for enlarging upon this because he was sure that not in Edinburgh or in all broad Scotland, probably not in Britain, were there ten men who had seen and conversed with Goethe. If the diaries which the speaker advised young men to keep are to be records of such interesting matter as that called up on Friday, it is to be hoped that all who can follow the advice will do so. The address was an enjoyable one from beginning to end, and will take high rank even amongst the inaugural addresses of the Royal Medical Society.

Edinburgh University General Council.

The statutory half-yearly meeting of the General Council of the University of Edinburgh was held on Friday last in the Examination Hall; Principal Sir William Muir was in the chair. The report of the business committee on the Universities Act was read, and in the course of observations on it Mr. Taylor Innes laid stress on the fact that extra-muralism and affiliation in connexion with the medical school would come up for the consideration of the Commission in a very serious way. It was a matter of great importance that the Edinburgh Extra-mural Medical School should bring forward its claims for regulating its position in the University in some such way as the St. Mungo's College had done in Glasgow. He thought it would be unfortunate if such new and untried proposals as were coming from that city should engross attention without at the same time full care being bestowed on the existing and successful system with which they were familiar, and which they had had so long to consider. In connexion with Dr. Hadden's motion at the last meeting, that the managers of the Edinburgh Royal Infirmary should be requested to alter their rule as to the qualifications of their physicians, so as to put the M.D. of Edinburgh University on the same footing as the Fellowship of the Royal College of Physicians, a letter dated April 29th last was read from the treasurer of the Royal Infirmary. "I submitted extract from the minutes of the General Council of the University, of date 16th inst., to the Managers of the Royal Infirmary at their meeting to-day, and was directed to inform you that the subject of the qualification of their physicians was carefully considered by them in November last, and that they now adhere to the decision then come to." This leaves the matter in *statu quo ante*, and only Fellows of the Colleges of Physicians and Surgeons of Edinburgh can hold the offices of physician and surgeon in the Royal Infirmary. Dr. Alexander James brought forward a motion, in which, he said, there was nothing new or revolutionary, though it will probably be difficult to convince those in authority on this matter. He moved, "That it be represented to the University Court that, in order to secure the advantages of publicity, any member of the general council of a Scottish university shall have the right to be present at any of the oral professional examinations in the University of Edinburgh, in the faculties in which they are held." He hoped no one would suppose that they were actuated by the idea that there was anything unsatisfactory. The contrary was the case, but statements went before the public by which they were apt to be misled, and he could conceive of no better way of enlightening the public than that which he proposed. It is not very long since Dr. James was successful in getting a similar motion approved of in connexion with the examinations in the colleges. In that instance the results have been eminently satisfactory.

The Volunteer Medical Staff Corps.

What is said to be the first of a series of lectures on subjects of interest to this corps was given in the large theatre of the Royal Infirmary on Friday afternoon. Admittance was not confined to members of the corps; all students were invited to attend, and those who accepted the invitation were rewarded with a capital lecture on "Army Surgeons in the Field," by Surgeon-Major Blair-Brown. He pointed out that in the Army Medical Service the staff was terribly small in numbers, especially now that there was an increased necessity for the medical corps in the field, on account of the difference in the nature of the wounds at the present day from those of the "round ball" and "smooth bore" days. He showed how in consequence of the closeness of the field hospital to the fighting line the medical staff had really very responsible and dangerous duties to perform, instancing their position in the centre of, and then at the corner of, the square formation, which had been adopted in some of the battles with our more uncivilised foes. They had to be prepared for all kinds of emergencies of the battle field, and an important step had been taken in training the soldiers how to stop hæmorrhage with their elastic braces. He then contrasted even our admittedly imperfect, because too scanty, medical corps of to-day with that of the Crimea, where the band was supposed to undertake the duties of the medical staff corps, and they knew as much about the matter as did the old women who sent them out. Professor Annandale, who occupied the chair, after thanking Surgeon-Major Blair-Brown, remarked he himself was an officer of the Edinburgh Medical Staff Corps, but he had not yet had sufficient courage to put on the uniform.

Edinburgh Lying-in Institution.

The work done by this institution has materially increased last year, as 165 cases have during that time been assisted. In some cases the assistance has been sorely needed. In the report issued, it is claimed that the

Digitized by Google

doctors, nurses, and lady visitors have all done their work well and have earned the gratitude of those whom they have helped. The majority of the cases assisted were those of wives of working men out of employment, or laid aside by illness or death. This is work quite outside the ordinary Maternity Hospital work, and is thoroughly deserving of liberal support.

Edinburgh, Oct. 29th.

DUBLIN.

(FROM OUR OWN CORRESPONDENT.)

Royal College of Surgeons in Ireland.

AT a special meeting of the President, Vice-President, and Council, held last week, the following professors were elected:—Surgery: A. H. Corley and William Stoker, Anatomy: F. Alcock Nixon. Midwifery: Samuel Mason. Medical Jurisprudence: H. Auchinleck. Medicine: John William Moore: Chemistry: Edwin Lapper. Materia Medica: G. F. Duffey. Zoology and Botany: E. McDowel Cosgrave. Pharmacy: G. F. Duffey. Ophthalmology: Charles E. Fitzgerald. There were contests in the chairs of Midwifery and Pharmacy; the other candidates were unopposed. On Nov. 7th an election for three professors will take place, one each in Anatomy, Physiology, and Pathology. Mr. Heuston will be appointed to the first, Mr. Scott to the second, while for the Professorship of Pathology the election, it is thought, will be between Dr. McKee, curator of the Museum of the College, and Dr. Myles. Mr. Heuston has resigned his seat on the Council, and for the vacancy Messrs. A. H. Corley and J. Bellew Kelly will compete, the election taking place on Nov. 5th.

Royal University of Ireland.

The annual ceremony of conferring degrees at this University was held last Monday, at the University buildings, presided over by the Marquis of Dufferin, Chancellor. In the course of an interesting address, he stated that in 1882 the entire number of candidates who entered for examination was 1898, while last year it was 3130, showing in the short space of six years an increase of 1232, or close on 64 per cent. He pointed out that their medical degree held a specially high place; the examination was admittedly a severe one, and they felt confident that each person to whom their degree was granted might be safely entrusted with the important duties and responsibilities inherent in the profession to which he had been admitted. He was happy to think that from very early days he had been in favour of the practice of medicine being open to women; and his Indian experiences had greatly deepened the strength of his convictions. In their Eastern Empire there are millions of women, from princesses and delicate and high-born ladies in the zenana to the wives even of the lower classes, who would rather die in the midst of their agony than allow a man to see their face, or in any way to treat them; and as for centuries they had been the victims of the most indescribable ignorance and abominable practices; they could therefore understand what a scope, both for professional success and for benevolent exertion, was open to women in that part of the world. In conclusion, he desired to state that in grateful recognition of this connexion with the Royal University of Ireland, he proposed to place at the disposal of the Senate an annual prize in the shape of a gold medal, to be competed for under such conditions as the authorities of the University might determine. Of the four studentships awarded this year, of the value each of £300, one in Biological Science was awarded to Denis J. Coffey, M.B.

Health of Dublin during September Quarter.

The deaths registered during the quarter amounted to 2107, equal to 23·9 per 1000, of which 359 were due to zymotic diseases, being an increase of 157 over the number for the previous three months, but 43 under the average number for the corresponding quarter of the past ten years. More than half the total mortality from zymotic affections was due to diarrhœa and dysentery. No death from small-pox has been registered in the district since March 3rd, 1888. A case was admitted to hospital in August last, but the patient has since been discharged. This is the only small-pox case in hospital since July, 1888.

Dublin, Oct. 29th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The French Surgical Congress.

IN continuing my *précis* of the most interesting of the many papers read at this Congress, I think that some account of that read by Dr. Demosthenes of Bucharest on the Surgical Treatment of Peritonitis and the discussion to which it gave rise claim space worthily in your columns, and may be read with profit. Dr. Demosthenes confined himself more particularly to the consideration of tubercular peritonitis, and remarked that the identity, anatomically speaking, of the pulmonary and abdominal serous membranes, and the pathological analogy subsisting between pleuritis and peritonitis, pointed to a similar, essentially surgical, treatment. Surgical intervention was indicated so soon as the presence of pus was ascertained, and it behoved us not to retard this intervention until the purulent collection was apparent from external examination, but to proceed to establish its existence by exploratory punctures immediately this existence was suspected. The destruction of peritoneal adhesions by traction or otherwise was not advisable, owing to danger of intestinal rupture; but should such an accident occur during the operation, and the perforation be not easily discovered, it was better to leave it to heal spontaneously, which it would do if the accummulation or stagnation of fæcal matter were prevented by strict antiseptics.—M. Demons of Bordeaux said that before discussing the surgical treatment of peritonitis it was necessary to be agreed as to the nature and gravity of the inflammation which one had to treat; and before appreciating results to well establish the proper moment for surgical intervention. The custom was to admit cases of peritonitis to purely medical wards; but peritonitis was a surgical affection about which there hung a tradition not to transfer it to surgical hands until it had undergone a course of expectant treatment on the medical side, which was at once long and prejudicial. He, the speaker, attributed the fewness of cases of peritonitis he had to treat largely to this cause. His first case was in 1885, and was one of the purulent kind following rupture of a suppurating ovarian cyst. He performed laparotomy, removed the cyst, and washed the peritoneal cavity clear of the exudation which it contained. Recovery was rapid and perfect. Should, then, laparotomy be generally recommended in cases of purulent peritonitis? The answer to this question was one full of moment. If, on the one hand, the operation was, as some advised, to be limited to making a small abdominal opening by which pus might drain away, and through which a cannula could be passed and the cavity washed out, the proceeding was simple and within reach of every practitioner. If, on the other hand, the operation should involve the making of an extensive abdominal incision and the laying bare and dressing of intestinal coils, the undertaking was much more arduous. As to the tubercular variety, there could be no doubt that laparotomy was the one thing indicated. The first time the speaker performed this operation in a case of tubercular peritonitis was one in which he had really diagnosed an ovarian cyst. Seeing his error, he quickly closed the abdominal cavity, but not before he had put, almost by hazard, some iodoform inside. To his surprise the result was excellent. He concluded by repeating he would advise laparotomy in tubercular cases, but that it was not necessary to remove the granulations which might be found invading the serous membrane.—M. Bouilly of Paris next read the notes of twelve cases of acute non-tubercular peritonitis on which he had operated with six successes. One was a traumatic case resulting from a kick from a horse. The operation was performed twelve hours after the accident, and revealed a gangrenous loup of intestine, which was resected. The cavity was then washed out and the operation, which was thus completed, resulted in the recovery of the patient. Of the remaining eleven four were cases of peritonitis resulting from the extension of lesions of the genital region. Of these three were saved by laparotomy, combined with antiseptic washing of the peritoneal cavity. Another was the desperate case of a poor woman who was admitted to the Paris Maternity with a ruptured uterus, which was found to extend to the bladder, and in which laparotomy was followed within two hours by death. The other six were cases of puerperal peritonitis,

Digitized by Google

of which two survived operation. Considering that in these twelve cases, with six successes, the conditions were discouraging and the symptoms extreme, M. Bouilly submitted his results were not unfavourable. In reply to M. Demons, he added that, inasmuch as in acute purulent peritonitis the object was to give prompt issue to pus, as in any other abscess, he was unable to see the advisability of a large incision, which complicated matters with no obvious advantages. He himself limited his incision to five or six centimetres, or from two inches to two inches and a half in length. This was long enough to admit his finger and a cannula, and by this means he directed his injection, composed of water, boiled, or rendered aseptic by the addition of a small quantity of bichloride of mercury.—M. Labbé of Paris had operated four times in cases of chronic or subacute peritonitis, with two successes. In three cases out of the four he avowed that the operation was the result of an error in diagnosis. On two occasions it turned out to be a case of tubercular peritonitis, but with signs so limited and defined that M. Labbé believed he was dealing with an ovarian cyst. Having made his incision he went no further and the patients recovered, which recovery struck him as it had M. Demons.—M. Campenon of Paris had operated once without success in a case of general peritonitis resulting from a perityphlitis. At the necropsy he was able to see that if he had well washed the whole of the peritoneal cavity, a vast abscess which he then found under the agglutinated intestinal coils between the rectum and bladder, and which was evidently the cause of death, would not have been overlooked.—M. Denucé of Bordeaux also reported a successful laparotomy in a case of purulent peritonitis following abortion, and MM. Brun and Rontier of Paris concluded the debate, which, in a word, resolves itself into unqualified advocacy of operative intervention in this disease, by recounting further cases of successful procedure.—A communication by M. Reclus of Paris, on the Production of Local Anæsthesia by Means of Cocaine, was listened to with considerable interest. He said he regretted to find that the use of cocaine for this purpose was not so general as it certainly deserved to be. It was reproached with being inefficient, and even dangerous. Now, he had made over 700 injections of cocaine, and he protested that these reproaches were not justified. It should be understood, however, that for the injections to bring about the desired effect they should be not merely subcutaneous but completely interstitial. Practised in this way, anæsthesia is always obtained, and is by no means, as has been stated, insufficient in tissues that are inflamed. As to duration of effect, he would put it at from three-quarters to one hour. In ano-rectal operations the use of this drug was most successful. Bone alone seems the only tissue not amenable to its influence. Speaking of the dangers, he declared that in his 700 injections he observed none, and that with ordinary care he believed none would be encountered. In the whole of the literature on the subject he could find a record of four deaths only which were laid to its account, and here considerable doses were given. But below seventy-five centigrammes he believed we were quite safe. There were doubtless certain symptoms, such as pallor of the face, loquacity, with a tendency to syncope, &c.; but with an ordinary dose of twenty centigrammes accidents were extremely rare. Generally, a dose of from ten to twelve centigrammes would be found sufficient, and, in a word, cocaine thus handled was, in the opinion of M. Reclus, an excellent and safe agent. In a subsequent communication I hope to give the substance of the debate on the treatment of Aneurysms of the Limbs.

The Hospitals of France.

At the moment when the question of hospital administration is engaging so much attention on your side of the Channel a few particulars culled from the report issued by the Bureau of General Statistics concerning the French hospitals may be of interest. From this it appears that the total number of hospitals of all kinds in France is 1658, these being subdivided into 404 hospitals proper, 806 hospital infirmaries, and 451 infirmaries. It results from these numbers that there is in France one hospital or infirmary for every 23,000 inhabitants. The number of patients treated in these establishments averages 400,000 per annum, giving a proportion of twelve persons treated for every 10,000 of the inhabitants. But while in the provinces this proportion is only 9, it rises in the Department of the Seine, or in other words Paris, to something above 40. Taking, then, an equal number of inhabitants, it is found that there are four times more persons treated in hospitals in Paris than in the country districts. The report embraces a period of fifteen years—viz., from 1871 to 1885,—and during this period the number of cases was in round numbers 360,000, that of deaths 40,000, which gives an average from year to year of nine cures for every single death. Two of these years were, however, exceptionally severe—viz., 1871, owing to the German invasion and the Commune; and 1884, by reason of the cholera epidemic. As to the income of these establishments in general, it goes on increasing. In 1833 it was over 51,000,000 fr., while in 1885, with nearly the same number of institutions, it had increased to 123,500,000 fr. The Paris hospitals are, however, in a less satisfactory financial state relatively to the provincial hospitals, but nowhere can the glaring deficits of the London hospitals be equalled. While, as I have said, the total income for 1885 for all the hospitals of France was over 123,500,000 fr., the total outlay was not quite 109,000,000 fr., thus leaving, as will be readily seen, a very comfortable margin. The average number of days spent by a patient in hospital is thirty for Paris and thirty-five for the provinces. The average cost per day in Parisian hospitals is 2 fr. 97 c., and in those of the provinces 1 fr. 77 c., giving a general average for all the hospitals and infirmaries of France of 2 fr. 4 c., or about 1*s.* 8½*d.* per day. It is to be noted further that in this country hospital abuse is not allowed to run rampant, for of the total revenue already quoted over 20,000,000 fr. are derived from the patients' own contributions. The contribution is levied as follows:—Whenever a person is admitted to a hospital full particulars as to his civil status are recorded; then due inquiries are made, and he is expected and required to pay according to his means and the accommodation he is provided with. Flagrant abuse of the charity is thus effectually prevented. On the other hand, there is no country in the world where charity goes farther to aid the really necessitous and deserving in the hour of trial. I ought perhaps to add that all the hospitals of France, with the exception of a few private ones, are under the administration of the Governmental department known as the Assistance Publique, which finds, to some extent, its parallel in your Local Government Board.

Paris, Oct. 29th.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

The Meeting of the German Anatomical Society.

THE proceedings of the third assembly of the German Anatomical Society began on the 10th inst., about 100 persons being present, and were introduced by a lecture delivered by Professor Wilhelm His of Leipsic, who is president this year. He proposed an alteration of the present custom of showing anatomical preparations to fellow anatomists at congresses. At present, he said, a hundred preparations and more are exhibited at a congress in a short space of time one after the other. No investigator could examine such a number with the necessary attention and leisure. A committee should be formed to select the more important preparations for exhibition. A second committee should be elected to act as final arbiter between investigators in scientific disputes. A historical instance of such a procedure was the dispute about a nerve-formation between Schlemm and Arnold, in which Johannes Müller was arbiter. The lecturer further proposed that every custodian of an anatomical collection should throw it open to his fellow anatomists, say for a month during the university vacation, and be ready with his assistants to give them the necessary information about the preparations. He further proposed the establishment of an institution for anatomical science on the model of the Zoological Station in Naples. His final proposal was that the Anatomical Society should make the reform of anatomical nomenclature one of its foremost tasks. A committee should be appointed for preliminary deliberations to that end, but the final work should be entrusted to a salaried investigator well versed in the history of anatomy. The last man who attempted to systematise the nomenclature of anatomy was Jacob Henle, who went on the principle of naming every anatomical structure exclusively according to its special

Digitized by Google

function. The lecturer opposed this principle. He wished to see the historical personal names, such as Meckel's ganglion, and Poupart's ligament, preserved, because, for one thing, they excited the curiosity of students of medicine as to the history of their science. He also opposed the universal Germanisation of anatomical terminology, as proposed by Marcus Herz and more recently by Dressler, because, for one reason, such a transformation would render mutual understanding between German and foreign anatomists still more difficult than it is. In the afternoon the members of the society visited the splendid new museum for natural science, which is not yet open to the public. Then they went to the zoological museum, which occupies the main part of this palace of science. The bi-partition of the museum is quite a new idea, one part being intended for the general public, the other for scientific investigators alone. The cabinets containing the zoological preparations are arranged in the so-called fish-bone form. The equipment of the museum excited general admiration.

The International Medical Congress of 1890.

The Budget of the German Imperial Home Office allots 80,000 marks as a contribution to the expenses of the tenth International Medical Congress which is to meet here next year, and assigns the following reasons: "The considerable expenses which these congresses entail are, as is proved by experience, only partly covered by the contributions of the members, so that, on former occasions, especially at the last congresses in Copenhagen and Washington, considerable subsidies were granted by the respective governments from public funds for the defrayal of the expenses. It will not be possible for the empire to lag behind other states in this respect."

An Interesting Operation.

A unique medical phenomenon, a native wing-membrane, which Professor Julius Wolff of Berlin has observed in a girl of nine, is being much discussed here at present. Between the thigh and the lower part of the child's left leg extends a peculiar formation, such as is found only between the upper and fore arms of the wings of birds, and which Professor Wolff therefore calls "wing-membrane." Three of the fingers of the child's right hand are webbed together, and her right leg terminates in a club-foot of the most pronounced character. The "wing-membrane," which is eighteen centimetres long and two centimetres thick, and covered all over by normal skin, is a smooth continuation of the soft parts, and the knee-joint could never be stretched, but only bent to a right angle, so that the girl could only move about on her knees. Professor Wolff resolved to make it possible for her to walk erect by removing the club-foot and cutting the wing-membrane through. The first of these two operations succeeded easily, with the help of water-glass bandages; but the second proved very difficult, and had not the desired effect. A year elapsed before the wound was healed and the possibility of stretching the knee-joint completely attained. The little girl is now able to walk erect without stick or crutch, and to go to school. Her gait is, of course, awkward, for the left leg is about twelve centimetres shorter than the right one. Professor Wolff's success is regarded as a decided triumph of surgical skill.

The New German Pharmacopœia.

After sitting for eleven days, the German Imperial Pharmacopœia Commission ended its deliberations on the 19th instant. Thanks to the careful preparations of the committee, it was found possible to settle all disputed points quickly. The rapid dispatch of business was due not a little to the circumstance that all divergent opinions were always referred in the first place back to the committee, which was thus enabled to come to an agreement beforehand, and to appear before the Commission with a firmly-formed opinion. Of the numerous new medicines which have come into use during the last few years only those were accepted the efficacy of which is universally recognised. All remedies for which a sure determination of identity is still wanting, or which are no longer generally in use, were omitted. The new edition of the legal Pharmacopœia will now be definitively prepared, and it is hoped that it will come into force next year. The Commission expressed the opinion that a German edition is desirable, and that the foreign expressions should be replaced as far as possible by German ones. Of course the scientific Latin designations which serve as headings are retained.

Berlin, Oct. 29th.

EGYPT.

(FROM OUR OWN CORRESPONDENT.)

Health of British Troops.

THE garrison in Cairo remains as it was, and includes two infantry battalions and details of every branch of the army, making a total of about 2000. Of this strength, 186 are to-day in hospital, and this includes the enormous number of fifty-one cases of enteric fever, two of them being officers. This high sick-rate is chiefly derived from the young soldiers of the Royal Irish Rifles, who, during July and August, were on duty up the Nile at Assouan and as far as Korosko, in consequence of the Dervish advance and their rout by the Egyptians at Toski. This regiment suffered much more from subsequent enteric fever, dysentery, and diarrhœa than the King's Own Scottish Borderers, who have now a sick rate of only 5 per cent. This is apparently due to the Rifles having suffered greater exposure and fatigue, for they were a longer time up the river and advanced farther southwards. Moreover, as it was important to move up British troops rapidly, and there was an insufficient number of steamers on the spot, *dahabiyehs* had to be employed, and when the wind failed tacking was necessarily resorted to. The 20th Hussars, who pushed as far as Toski, had as a penalty a sick-rate afterwards of 15 per cent. The sanitary arrangements were carried out as perfectly as was possible; when in camp the men lived in huts, and were supplied with earth-closets and filtered water, but on the river it was found impossible to filter all the drinking water. It must be remembered that the Nile during the summer months is thick with suspended salts and earth, and that thirst and work necessitate almost perpetual drinking. A boat was told off to take water from the centre of the stream, and native filters were kept constantly in use. The experience was similar to other campaigns in Egypt, for the sick-rate was not abnormally high until after the stress was all over and the men were back again in Cairo. But it is satisfactory to know that the percentage of sick is now slowly diminishing. Nobody knows better than the Soudanese that it is difficult for us to send English troops up the river during the hottest months, hence they so time their advance. We must obviously make use of our combined Egyptian and English garrison at the frontier, and the result will be the same. Egyptians can safely drink unclean water and breathe foul air, while the young Englishman, in spite of filtering and other precautions, falls a victim to the intestinal diseases against which he has not been "vaccinated" in early life. Possibly it might be better to regard the English soldier during a campaign in the hottest months merely as a fighting machine, and to employ native labour for all sorts of fatigue duty.

The School of Medicine

The official journal of the Egyptian Government of Oct. 16th proclaims that Dr. Hassan Pasha Mahmoud was on Oct. 10th appointed director of the Government Medical School, at a salary of £750 a year. Hassan Pasha is a nephew by marriage of Riaz Pasha, the Prime Minister, and is son-in-law to one of the under-secretaries of State. In order to make room for him, the director, who under English advice has of late years greatly improved the school, has been shelved, and the vice-director, one of the very few scientific Egyptians, and lately very highly commended for his natural history work by Professor Virchow, has been deprived of his appointment, though not of his professorship. The late director has introduced practical anatomy; has persuaded the Government to build dissecting rooms, museums, and laboratories; has permitted the students to work for their last year in the hospital wards; and has done many other things which have contributed to the marked improvement there is in the medical school. The appointment of Hassan Pasha is the most unpopular among both natives and Europeans which could possibly have been made.

Cairo, Oct. 21st.

SEWERAGE WORKS, HUDDERSFIELD.—On the 24th ult., Mr. W. H. Jessop, chairman of the Sanitary Committee of the Corporation of Huddersfield, performed the ceremony of cutting the first sod of the new sewerage works at Deighton, the estimated cost of which is £40,000.

THE ITALIAN MEDICAL CONGRESS.

(*Concluded from page 873.*)

THE afternoon sitting of the 16th was signalised by a brisk discussion evoked by a paper of Professor Petrone of Catania on "Two Cases of Hepatic Cirrhosis cured with Milk Diet, Diuretics, and Cathartics, and Hot and Moist Cataplasms applied to the Abdomen." Dr. Petrone maintained the possibility of curing similar cases even in the state of hepatic atrophy, but not when degeneration of the parenchymatous elements of the viscus had been established. Prof. Cardarelli held another opinion, as wholly pessimistic as Petrone's was optimistic. Out of 100 patients suffering from hepatic cirrhosis he had not succeeded in curing one, and suggested that in Petrone's cases an error of diagnosis had been committed. Professor De Renzi's experience rather favoured Dr. Petrone's than Professor Cardarelli's, and Professor Semmola then intervened with a criticism of Cardarelli's view as "*a prioristic*," and defended Petrone's position from his own clinical practice, reinforced by that of other clinicians, Italian and foreign. The battle now became general. Professors Senise and Ria never knew any case, diagnosed as one of hepatic cirrhosis, to have been cured; while Professor Queirolo contended that, at times, by the development of a collateral circle, there may be a suspension of the pathological process, a suspension which may be repeated at intervals of varying duration. Professor Maragliano insisted, as a factor in the case, on the functional activity of the heart which sometimes succeeded in cutting off from the circulatory system the liver with the vena porta. When the heart no longer gives compensation, then ascites and other derangements set in. Professor Semmola returned to his position, and rebutted Professor Queirolo's argument that there are intermittent hepatic cirrhoses. He further maintained the curability of the malady in its hyperplastic or hypertrophic stage, and cited instances in point. Replying on the whole case, Dr. Petrone complained that want of time had prevented him from adducing all the facts and illustrations he had accumulated. He concluded by joining with Professor Semmola in a recommendation that the Congress should appoint a committee to make a special study of the question and report on it at next year's meeting.

When the Congress resumed its sittings (17th) the report of Professors Murri and Cantani on "Gout" proved as fruitful of discussion as that on malaria. Professor Murri took in hand the pathogenesis of the disease, and examined at great length and with much severity the theories of Wierordt, Ebstein, Gerhardt, and Pfeiffer. He criticised the view that uric acid in the blood attacks some tissues and induces necrosis of them, and that on these necrosed tissues tophi are formed. This theory, he said, is opposed by another, which makes the necrosis of the tissues depend on various causes, on their greater vulnerability for example. But to speak of vulnerability and not give a reason for it or tell in what it consists is, he said, to say nothing. Why are tophi formed by preference on the idle hands of ladies and not on their tortured and boot-constricted feet? Why on the ears rather than on the nose? He confronted gout with leukæmia and other diseases in which uric acid prevails in the urine, but in which there is no access of gout. What pathological condition is pre-existent to gout? According to Wierordt, nephritic symptoms do not exist in the gouty. Then why is uric acid secreted in the urine of the gouty in greater quantity before the fit and in less quantity during the fit? Analysis finds in the gouty more uric acid in the blood and less in the urine. Nor does the diminished alkalinity of blood explain the whole of the morbid process. Uric acid, he maintained, is produced by imperfect oxidation of the albuminates, as urea represents their complete oxidation. Concluding that the presence of uric acid in the blood of the gouty is due to impaired power of oxidising the tissues, he expressed the hope that further research would continue to be made on a more elaborate scale than heretofore with a view to solve this most arduous problem. Then followed Professor Cantani on the treatment. He, too, instituted a "march past" of previous, especially German, clinicians on the subject, and dwelt at much length on Pfeiffer's acid treatment, which he condemned. Considering heredity and an excess of albuminates in the daily food as principal factors in the gouty diathesis, he laid down rules for an azotised regimen, while allowing vegetables and fruit in small quantity; and, further, prescribed gymnastics, systematic movement, salicylate of soda, alkalies, and alkaline beverages. The discussion that ensued lasted all through the forenoon sitting and the greater part of the afternoon, and was perhaps the most interesting, as it was certainly the most animated of the series. It ranged over many of the derivative affections of the gouty, and evinced the attention given by Italian pathologists and therapeutists to the cardiac and neurasthenic sequelæ of chronic gout. Professors Alivia, Rummo, Petrone, Sonzino, Franco, and Olivieri were the chief interlocutors, and they were followed by Professors Murri and Cantani in defence of the positions maintained in their report. The latter pointed out that in Italy there are many alkaline springs known to but a few and quite untried. He further expressed the hope that these would be adequately studied and made universally available. "We have," he said, "waters superior to those of Vichy and Karlsbad, but almost unknown or fallen into discredit through having been improperly worked by private and non-professional speculators."

Papers of minor interest, though none of them without value for the practitioner, occupied the remainder of the sitting and part of that of next day (18th); after which the Congress was dissolved in a few congratulatory and encouraging sentences by its president, Dr. Baccelli. Alluding to the preponderance of the results of German science and practice in the subject matter of their discussions, he said: "Learned Germany will have in us a faithful ally not only for the peace of Europe but for scientific progress. We Italian physicians, ready for every sacrifice called for by the unity, the freedom, the greatness of our country, express the hope that, rather than with the laurels of battle, Italy will wreathe her forehead with the gentle and beneficent laurels of peace."

CORRIGENDUM.—On page 873, first column, lines 6, 14, 21, 39, and 53, for "Cantani" read "Baccelli." At line 7 from the foot of page 872, second column, there should have been no comma after "retired."

THE ROYAL COLLEGE OF PHYSICIANS.

AT the ordinary quarterly meeting of the comitia of the Royal College of Physicians held on Thursday, Oct. 31st, the President nominated Dr. Richard Quain and Dr. Samuel Wilks as Vice-Presidents for the ensuing year. He then announced that Sir Henry Pitman had resigned his appointment upon the Committee of Management, and in graceful terms moved an expression of the grateful thanks of the College to Sir Henry Pitman for his valuable services during many years. It was also agreed that the College should present a robe to him as Emeritus Registrar. The following gentlemen were then admitted Members of the College:—G. A. Carpenter, M.B. Lond.; J. Davison, M.D. Queen's Univ.; E. B. Forman, M.D. Lond.; E. Goodall, M.D. Lond.; E. H. Greves, M.D. Edin.; A. A. Jamison, M.D. Glasg.; A. P. Luff, M.B. Lond.; W. Newman, M.D. Lond.; E. C. Perry, M.D. Camb.

Among the communications addressed to the College, one of the most important was a letter from the Foreign Office, notifying further restrictions on the practice of medicine by Englishmen in France, it having been agreed that English doctors will be allowed in exceptional cases only to present themselves for examination in order to acquire the right to practise in France.

An announcement was made of the award of the Murchison Scholarship to Arthur John Whiting, M.B., C.M. Several other official announcements were received.

After some little discussion a resignation of membership of Patrick Fraser, M.D. (Member, 1839), was formally accepted.

The Treasurer presented his audited accounts for the year ending Sept. 29th last, showing that the income of the College had amounted to upwards of £20,915, and its expenditure to £18,773, leaving a balance at the bankers' of over £2142.

The quarterly report of the Finance Committee was then presented, and some discussion ensued upon a recommenda-

Digitized by Google

tion to increase the stipend of the Treasurer. Upon the motion of Sir Henry Pitman, seconded by Dr. Norman Moore, it was agreed to increase this to three hundred guineas a year.

Dr. Allchin's motion, which referred to a new bye-law of the College, was, after a few words, postponed to the next meeting, to obtain the opinion of counsel.

Several other important matters were also deferred owing to the lateness of the hour, and the meeting ultimately adjourned to Thursday, Nov. 7th.

THE SERVICES.

ARMY MEDICAL STAFF.—Brigade Surgeon Wm. Tanner, from half pay, is granted retired pay (dated Oct. 30th, 1889).

ARMY MEDICAL RESERVE OF OFFICERS.—Acting Surgeon Arthur Corrie Keep, M.D., 2nd Volunteer Battalion, the Worcestershire Regiment, to be Surgeon, ranking as Captain (dated Oct. 26th, 1889).

VOLUNTEER CORPS.—*Rifle:* 1st Volunteer Battalion, the Royal Warwickshire Regiment: Arthur Thos. Holdsworth, M.D., to be Acting Surgeon (dated Oct. 26th, 1889).

Obituary.

DR. ADOLF WISLICENUS.

"THE Romance of Medicine" might well claim as one of its heroes this octogenarian practitioner who died at St. Louis, U.S., at the close of last month. Dr. Adolf Wislicenus was born in 1810 at Dornfeld, in Thuringia, and at the usual age left the gymnasium for the university, to qualify for the medical career. He studied at Göttingen, at Jena, and at Würzburg, until, shortly before graduation, he became compromised in the famous "Frankfurter Attentat" and had to flee the country.

In the spring of 1833 a conspiracy had been formed in Frankfurt-on-the-Main to avenge itself on the Federal Diet, which by its severely restrictive press laws had roused the citizens, particularly the younger portion, including many students in the several faculties, to something little short of madness. In this conspiracy Adolf Wislicenus, with Matthiä and others of the medical *Burschenschaft*, took a leading part—the design being to blow up the Diet. On April 3rd, 1833, the attempt was made. The guardhouse was carried by storm, and the conspirators were within an ace of effecting their purpose when the military appeared in the nick of time, arrested nine of the youths, and put the others to flight. Among those who, after hairbreadth escapes, eluded the emissaries of the law was young Wislicenus, who found his way to Switzerland, where at the University of Zurich he resumed the broken thread of professional study. He graduated with distinction, and in 1835 proceeded to the United States. Ultimately settling in practice at St. Louis, he rapidly formed an extensive *clientèle*, of which his compatriots were the nucleus, and realised a handsome income, which enabled him to give time to pure science and also to travel in and beyond the States. He made memorable visits to Mexico and the Rocky Mountains, and published most interesting records of his observations and experiences. By all classes he was looked upon as an enthusiastic and large-minded reformer, an honest and benevolent survivor of the "Vor Achtundvierziger" men—as the precursors of the revolution of 1848 are familiarly called, and steps, we understand, are being taken by the German colony, not in St. Louis only, to perpetuate by some suitable memorial his name and his life-record.

DONCASTER INFIRMARY AND DISPENSARY.—The annual general meeting of the governors and subscribers of this institution was held on Oct. 28th, the Mayor presiding. The report stated that the subscriptions amounted to £20 less than last year. The total income had been £1850, and the expenditure £1450. The report was adopted, and votes of thanks were passed to the medical staff and other friends and helpers.

Medical News.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—The following gentlemen, having conformed to the bye-laws and regulations and passed the required examinations, were, at a meeting of the College on Oct. 31st, admitted Licentiates:—

*Barker, J. Collier, St. Bart.'s.
Barker, J. Hamer, Manchester.
Bates, Stephen H., Univ. Coll.
Bentham, A. O., Manchester.
Bergin, George F., Bristol.
Bevan, T. Webb, St. Bart.'s.
Beyts, William George, Guy's.
Birkenhead, H., Manchester.
Boase, William G., St. Bart.'s.
Borrett, George Goss, London.
Cameron, Ewan G., Middlesex.
Carrell, G. N. Piccaver, Guy's.
Cato, A. McLean, Westminster.
Cayley, Cyril Henry, Middlesex.
Cheetham, S. W., Liverpool.
Cleveland, R. A., Univ. Coll.
Collett, H. G. O., King's College.
Collins, A. B., St. Bart.'s.
Conway, B. W., Manchester.
Cooke, J. A., Manchester.
Cuthbert, H. Pierce, London.
Dane, Robert, Middlesex.
Dewhurst, J. H., Camb. and St. Thomas's.
Dickson, T. H., Camb. and St. Thomas's.
Dowse, H. E., Westminster.
Duigan, William, London.
Edmonds, G., St. Bart.'s.
Edwards, J. H., St. Bart.'s.
Elam, George, Middlesex.
Elliot, R. H., St. Bart.'s.
Enraght, W., St. Bart.'s.
Evans, T. H. Fencott, St. Bart.'s.
Foley, C. N., St. Thomas's.
George, A. W., Edin. and St. Thomas's.
Gibbs, S. F., St. Bart.'s.
Giffard, G. G., St. Bart.'s.
Glinn, George F., St. Mary's.
*Godding, James, London.
*Griffin, John H., St. Bart.'s.
Heath, A. J., Univ. Coll.
Hickley, A. M., St. Mary's.
Higginson, J. W., Univ. Coll.
*Hooton, W. A., Manchester.
*Hughes, A. E. P., St. Thomas's.
Hugo, E. V., St. Bart.'s.
Jamieson, S., Edinburgh.
Kelbe, W. E., Guy's.
Khan, Masha Allah, London.
Kitchin, H. B., Univ. Coll.
Knox, Jas. K., Camb. and St. Mary's.
Lewers, Alexander, St. Mary's.
Lewis, L., Westminster.
Ley, G., Univ. Coll.
Lightbody, J. H., Liverpool and St. Bartholomew's.
*Livsey, W. E., Liverpool.
Major, A. C., London.
Manning, H. P. O., Guy's.
*Mansbridge, J., Charing-cross.
Martin, A. E., London.
Meyers, D. C., Toronto.
Milner, A. S., Charing-cross.
Morris, G., St. Bartholomew's.
Naylor, J., St. Bartholomew's.
Neill, B., St. Bartholomew's.
Norburn, A. E., Guy's.
Norton, E. E., Middlesex.
O'Leary, A. P. E., Bristol.
Olive, E. J. P., St. Bartholomew's.
*Ormerod, H. L., Bristol.
Osborne, O., London.
*Paget, P., Guy's.
Paul, M. E., London.
Pires, G., Bombay and Univ. Col.
Pollock, C. S., St. George's.
Powers, C. H., St. Mary's.
*Pratt, E. F., Birmingham and Newcastle-on-Tyne.
*Purnell, P., Guy's.
*Rayne, W. T., Westminster.
Rees, J. M., St. Bartholomew's.
Rendel, A. B., St. Bart.'s.
*Rowlands, H. P., Guy's.
*Rubinstein, D., Leipzig.
Rudyard, H. A., Univ. Coll.
Saunders, F. W., Cambridge and St. Bartholomew's.
*Scott, G. H., Leeds.
Shepherd, H. B., St. Thomas's.
Simmons, F. H., St. Bart's.
Simpson, G. W., Westminster.
*Smith, H. W., Birmingham.
Snape, E. A., Charing-cross.
Speechly, H. M., London.
Stabb, A. F., St. Thomas's.
Standage, R. F., St. Bartholo's.
Stokes, W. G. G., Camb. and St. Thomas's.
*Sullivan, E. Henry Charles, St. Thomas's.
Taylor, E. E., Edinburgh.
*Tindall, F. D. P., Guy's.
*Toller, S. G., St. Thomas's.
Tuppen, H. S., St. Thomas's.
*Verano, L. L., St. Bartholo's.
Walters, A. P., Univ. College.
Warde, W. B., St. Bartholo's.
Watkins, H. E., Manchester.
Wightman, H. T., Sheffield.
Williams, E. McK., Univ. Coll.
*Williams, E. G. H., Charing-cross.
Woodall, R. W., London.

* Candidates who have not presented themselves under the regulations of the Examining Board.

ROYAL UNIVERSITY OF IRELAND.—On the 28th ult. the following degrees were conferred by the Marquis of Dufferin, Chancellor of the University:—

Doctor in Medicine.—Richard Rolt Davidson, Chas. Donovan, Joseph Everard Dunlop, John M. Hall, James Hamilton, Henry Harley, William O'Donnell, William Latimer Storey.

Bachelor in Medicine.—John William Wolfe (with first class honours), Isaac Banks, James Byrne Coleman, Joseph Eldon, James Matthew Fagan, Thomas McDermott, Francis McKee, James Adrain, Joseph Patrick Clarke, William Ekin, Alexander Erskine, James Fulton, Hugh Todd Gill, William James Gregory, William Healy, Paul Patrick Jennings, Joseph John Loftus, Arthur Saul McComiskey, Horace Townsend Merrick, Alex. Thomson Morrison, Robt. Jackson Munn, Matthew Joseph O'Regan, Henry Kennedy Smyth, Joseph Smyth, James Taylor, Samuel Henry Withers.

Master in Surgery.—James Byrne Coleman.

Master in Obstetrics.—Patrick F. Graham, Hugh McMillan, George Matthew Thompson.

Bachelor of Surgery.—James Adrain, Isaac Banks, Joseph P. Clarke, James B. Coleman, Richd. Rolt Davidson, Charles Donovan, Joseph Everard Dunlop, William Ekin, Joseph Eldon, Alexander Erskine, James M. Fagan, James Fulton, Hugh Todd Gill, William James Gregory, John Moore Hall, James Hamilton, Henry Harley, Wm. Healy, Paul Jennings, Joseph J. Loftus, Arthur W. McComiskey, Thomas McDermott, Francis McKee, Horace Townsend Merrick, Alex. Morrison, Robert Jackson Munn, Wm. O'Donnell, Matthew Joseph O'Regan, Henry Kennedy Smyth, Joseph Smyth, William Latimer Storey, James Taylor, Samuel Henry Withers, John Wm. Wolfe.

Bachelor of Obstetrics.—James Adrain, Martin Atock, Isaac Banks, James Carroll, Joseph P. Clarke, James B. Coleman, Richard R. Davidson, Charles Donovan, Joseph Everard Dunlop, Wm. Ekin, Joseph Eldon, Alex. Erskine, James Fagan, James Fulton, Hugh

Digitized by Google

Todd Gill, Wm. James Gregory, John Moore Hall, James Hamilton, Henry Harley, William B. Hayes, William Healy, Paul Jennings, Joseph Loftus, Arthur McComiskey, Thomas McDermott, James Macdonald, Francis McKee, Edward Magennis, Horace Merrick, Alex. Thomson Morrison, Robt. J. Munn, Wm. O'Donnell, Matthew O'Regan, William Richardson, Henry Kennedy Smyth, Joseph Smyth, Wm. Latimer Storey, Jas. Taylor, Samuel Henry Withers, John William Wolfe.

Diploma in Sanitary Science.—John Gillespie Deacon, Robert Lynn Heard.

DONATIONS. — Mr. C. Kennedy, J.P., has given £250 and Dr. McSwiney £25 to Jervis-street Hospital, Dublin.

THE ROYAL MEDICAL BENEVOLENT COLLEGE has received £100 under the will of the late Baroness Clementina von Roemer.

MEDICAL MAYOR.—Mr. John Sherburn, M.R.C.S., on the invitation of the Hull Town Council, has consented to hold the Mayoralty for another year.

PUBLIC BATHS, GUILDFORD.—The Mayor and Corporation of Guildford formally opened these public baths, on the 25th ult., which have been erected at an outlay of £2800.

LUTON.—On Tuesday, Mr. Cyril Flower, M.P., opened a new Children's Sick and Convalescent Home at Luton, which has been established by a gentleman who desires to remain unknown.

CAVENDISH COLLEGE, CAMBRIDGE.—The opening of the new College Hall will take place on Saturday, Nov. 16th, at two o'clock. There will be a luncheon, at which the Marquis of Hartington will be present.

SCARLET FEVER IN BIRMINGHAM. — On the 30th ult. there were 440 patients in the hospital. The wards are not quite full, which is in some measure satisfactory to know.

HOSPITAL SUNDAY IN BIRMINGHAM.—Last Sunday was sadly interfered with by the continued wet and cold. The amount up to date is £4269 9*s.* 5*d.*, and it is proposed to supplement this by additional collections next Sunday.

OPEN SPACES.—Mr. Alderman Ward, Mayor of Leeds, formally opened on the 26th ult. a new recreation ground for the use of the inhabitants of Rodley. The present area of the site is nine acres, and the purchase money amounted to a little over £1400.

THE SOUTHERN (AMERICA) SURGICAL AND GYNÆCOLOGICAL ASSOCIATION.—The session of this Association will be held in Nashville, Tennessee, on Nov. 12th, 13th, and 14th, 1889, under the presidency of Dr. Hunter McGuire, of Richmond, Virginia. Members of the medical profession are cordially invited to attend. The secretary is Mr. W. E. B. Davis, M.D., Birmingham, Alabama.

THE CITY SCHOOL OF CHEMISTRY AND PHARMACY.—The winter session at the above school was opened at the commencement of this week. In all former years the school opened simultaneously with the metropolitan hospital schools, but this year an unavoidable delay occurred owing to the illness of the principal, Mr. Maurice Williams, who has now sufficiently recovered to resume his customary duties.

PARIS EXHIBITION PRIZES.—The well-known firm of M. G. Masson, medical and scientific publishers, has been awarded a "grand prix" at the Paris Exhibition in Class 8 (organisation, method, and material of higher education), and also in Class 9 (the press and library). In Class 14 (medicine and surgery) of the Exhibition "grands prix" have been awarded to Baretta, Mariand, Claude Martin, Raoul Mathieu, and Tramand, all of France. Fourteen gold medals and twenty-six silver medals were also awarded in this class.

NOTTINGHAM GENERAL HOSPITAL.—The 107th anniversary meeting of this institution was held on the 24th ult., at the county hall, the Duke of Newcastle, the president, occupying the chair. The report, which was adopted, showed that during the past half year the work of the hospital in all its departments had been efficient and satisfactory. The total number of patients under treatment was 788, against 783 in the corresponding months of last year. The financial condition of the hospital continued a source of anxiety to the Board. The appropriation, as income, of legacies which should have been capitalised has been an unavoidable alternative.

SUNDERLAND AND NORTH DURHAM EYE INFIRMARY.—The report just issued states that this infirmary has now been in existence for fifty-three years, and treats yearly 1000 new patients, receiving as many in-patients as the inadequate accommodation will allow—viz., five. The committee consider that, with what they have in hand, an additional £4000 would enable them to erect a suitable and adequate eye infirmary free of debt, and they accordingly appeal for assistance to that end.

LITERARY INTELLIGENCE.—The approaching publication of a work on the "Bibliography of Venereal Diseases," from the earliest writings on syphilis at the close of the fifteenth century to the present day, is announced by Hanstein, Bonn (London: Dulau and Co.). The work, which is compiled by Dr. G. K. Prosch, will consist of three volumes, and will contain analytical summaries of the vast field of literature now covered by this subject. The first volume is announced as being ready, and the others will appear in 1890.

DR. CHAUTEMPS. — Last Tuesday morning Dr. Chautemps, President of the Municipal Council of Paris, who is now on a visit to London, went over the French Hospital near Leicester-square, and under the guidance of Dr. Vintras, the head physician, examined the plans of the new building approaching completion in Shaftesbury-avenue, and which will be inaugurated next spring. Dr. Chautemps expressed gratification at what he had seen, and in the name of the Municipal Council of Paris made a donation of £40 each to the French Hospital and to the French Benevolent Society.

TAUNTON AND SOMERSET HOSPITAL. — At the annual meeting held in connexion with this institution last week, the report, which was adopted, stated *inter alia* that a long-felt want had been supplied by the provision of a casualty ward near the principal entrance. Important improvements had been made in the sanitary arrangements. The committee pleaded earnestly for liberal donations wherewith to rebuild the cottages which are now in a most dilapidated state, as well as to effect other important additions and improvements which were strongly urged by the medical staff.

VOLUNTEER MEDICAL STAFF CORPS: 1ST (LONDON) DIVISION.—The annual competition for the Challenge Shield took place on Saturday, Oct. 26th, at Westminster Hall. Three companies competed—viz.: No. 1, Surgeon V. Matthews; No. 4, Surgeon-Major J. A. Watson; No. 5, Surgeon J. E. Squire, M.D. Surgeon J. Falvey, M.S., Assistant Instructor to the Medical Staff Depôt, Aldershot, kindly acted as judge. The companies were put through various movements in bearer, company, and stretcher drill, and examined in bandaging and first aid to the injured. After a spirited competition the Shield was awarded to No. 1 Company, the contest, however, having been very close. Surgeon Falvey having addressed the officers and men of the corps, and complimented them on their work, Surgeon-Major Platt, V.M.S.C., in the absence of Surgeon-Commandant Norton, thanked Surgeon Falvey in the name of the corps for his kind services, bringing a most interesting afternoon's work to an end. The men of the winning company are recruited from the medical schools of King's College, University College, Charing-cross, Middlesex, and St. George's Hospitals.

SUCCESSFUL CLAIM AGAINST A SPANISH LIFE ASSURANCE COMPANY.—Spanish Life Assurance Companies are not, as it would seem, content with getting the medical attendant of one of their clients to fill up a paper of questions and to forward it to the office by post, as is usually the case in this country. They are apt to require the attendance of the doctor at the office, and to put him through a long string of oral questions in addition to making him fill up an elaborate form; and to crown all this, they never think of paying him a fee. They will, however, probably have to change their practice. A medical man, one of whose patients died recently while assured in a certain society, said to be one of the most wealthy of Spanish life assurance companies, having received a request to attend at the office of the said company, and, being detained a considerable time, astonished the manager shortly afterwards by sending in a bill for 125 fr. This the manager declined to pay, as he declared no medical man had ever before even asked for any remuneration. The doctor took the matter into court, with the result that the company was ordered to pay the amount charged, with the expenses of the action.

CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, VICTORIA-PARK.—On Monday, the 28th ult., an address was delivered at the above hospital by Sir J. Risdon Bennett, M.D., F.R.S., as an introduction to the course of clinical lectures and demonstrations which have lately been established by the staff with the object of utilising the large resources of clinical material which the practice of the hospital affords. The address (which we hope in a future number to print in abstract) was listened to with much interest by a crowded audience composed largely of former and present pupils and resident officers of the hospital, and the proceedings were fittingly concluded by a cordial vote of thanks to Sir Risdon Bennett, proposed by Dr. Thorowgood and seconded by Mr. Julian Hill, one of the lay committee, who made graceful allusion in so doing to the cordial relations which had invariably subsisted between the committee and the medical staff.

ROYAL ACADEMY OF MEDICINE IN IRELAND.—The following is the list of office-bearers for the ensuing year:—President: Samuel Gordon. Medical Section—President: L. Atthill. Council: J. H. Benson, E. McD. Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editors."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed to the Sub-Editor.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "to the Publisher."*

We cannot undertake to return MSS. not used.

SALARIES AND REPORTS OF MEDICAL OFFICERS OF HEALTH.

To the Editors of THE LANCET.

SIRS,—In your paragraph in last week's issue of THE LANCET on the above subject, you seem to infer that medical officers of health are only required to send their annual report to the Local Government Board, whereas the Act of 1888 distinctly states (Section 19) that a similar report must be sent to the clerk to the County Council.

I am, Sirs, your obedient servant,
J. HENRY ASHWORTH,
Med. Officer of Health, Halstead Rural Sanitary Dist.

Halstead, Essex, Oct. 29th, 1889.

*** Our annotation of last week dealt only with the point raised in Section 24 of the Local Government Act, 1888—namely, that half of the salaries of such officers of health as had not yet sent in to the Local Government Board "such report and returns" as are required of them for the past year was now liable to be forfeited. It is not until the beginning of next year that the requirement as to sending a copy of the annual report to the County Council, under Section 19, comes into operation.—ED. L.

Mr. A. Greenleaves.—There is no practical difference in the nutritive value of meat which has been frozen in the fresh state and that which is sent to market in the ordinary way. The only loss that meat sustains by being frozen is said to be that the flavour is slightly impaired.

Mr. Henry C. Wilkie.—Cobbold, Leuckart, Kuchenmeister, Davaine.

EXAMINERS IN VACCINATION FOR WALES.

To the Editors of THE LANCET.

SIRS,—Having been away from my native country for many years, and not having availed myself of the opportunities offered during my studentship for acquiring the necessary licence in vaccination, I find that I must cross the Channel (this being the nearest point) before I can meet with a person authorised to grant this formal document. Why Wales has not been honoured with such a representative I do not know. It certainly cannot be on the ground of incompetency. If examiners were appointed nearer home it would be a convenience, as well as a saving of expense, to those candidates who have, like myself, neglected a past opportunity. Great centres like Cardiff or Swansea ought to possess the necessary attractions.

I am, Sirs, your obedient servant,
JOHN HARRIS JONES.

Swansea, Oct. 26th, 1889.

RESPONSIBILITY UNDER THE NOTIFICATION ACT.

To the Editors of THE LANCET.

SIRS,—May I ask, in reference to the notification of disease, how it would happen (1) if a medical man did not recognise the nature of the disease, which it is often difficult to do; and (2) if he gave notification of a disease which did not turn out to be infectious? In the latter case might he be liable to prosecution by the patient or his relatives for damages, or is the responsibility to rest on the medical officer of health?

I am, Sirs, yours truly,

Oct. 26th, 1889. A. H. NEWTH, M.D.

* The questions put by our correspondent are important. 1. Undoubtedly the responsibility of certification rests with the person who certifies. There is nothing in the Act to require him to certify till he shall have "become aware that the patient is suffering from an infectious disease." In difficult or dubious cases he must give the patient the benefit of the doubt; but he must be careful that the dubiousness is in the case and not in his own mind and knowledge. A medical man would not be punished, we apprehend, for an honest reasonable doubt in a difficult case.—2. If he makes a mistake and "notifies" a disease which turns out to be non-infectious he must bear the burden of it. There is nothing in the Act to throw the onus of diagnosis on the medical officer of health, though no officer of health would, we think, refuse his assistance in a serious difficulty. We repeat in doubtful cases the patient must have the benefit of the doubt. The Act will bring delicate and difficult duties, and will give an occasional illustration of the fallibility even of medical men. But honest and fair mistakes will not be severely judged by reasonable patients or judges.—ED. L.

G. J. M. wishes for information as to where a boy aged eleven years, middle class, requiring care and supervision, can be placed (institution or otherwise). He is not deaf, but dumb, and inclined to be unruly, but up to the present has been managed at home by an ordinary nurse girl, with a little sister. It is doubtful if he can be taught anything.

D.—Most offices would accept such a life, probably at little, if any, advance on the ordinary rates.

Mr. A. W. Macdougall.—The discussion of the subject is closed.

PRACTICE AT THE CAPE.

To the Editors of THE LANCET.

SIRS,—In answer to the query as to the prospect of practice at the Cape, will you allow me to say that a smart man can always get on out there? We have not many London M.D.'s; these gentlemen generally procure extensive practices. What are wanted there are really smart men. We have many ordinary practitioners, and even these seem to succeed. I doubt whether a man with ordinary qualifications could do worse than go to Africa. The field for work is extensive, and where one practitioner will fail another may prosper. Of course, care must be taken to avoid certain overcrowded localities, as the following extract out of the latest Cape papers will show:—"There are fifty-six medical men practising—or trying to do so—in Johannesburg." This rush of medical men is, of course, on account of the gold discovery; but by a little reasoning one is soon convinced that they must have had a practice somewhere in the colony, and that the said practice is now vacant, and open to any smart, energetic man. Again, I must say we want the best qualifications. As to the climate, nothing can be better; it will at times be found hot, but one soon becomes used to that. I would not advise the abandonment of a fair London practice.

I am, Sirs, yours truly,

London, Oct. 23rd, 1889. NITCH SMITH, M.S. (of Africa).

THE LATE ALBERT SMITH'S WORKS.

To the Editors of THE LANCET.

SIRS,—In answer to Mr. Alfred Corrie, I beg to state that "The Medical Student," by the late Albert Smith, was published at a shilling by Messrs. Routledge, Warne, and Routledge, to which firm your correspondent had better address himself. The cardboard cover of the book bears the *fac-simile* of a capped phial, with the labelled direction, "Half to be taken immediately, and the other half in an hour if the depression is not removed." I may say that it is my intention to introduce a few extracts from this hilarious volume into my forthcoming paper on "Mirth and Medicine; or, the Philosophy and Physiology of Fun and Physic."

I am, Sirs, yours truly,

Leeds, Oct. 29th, 1889. CLARENCE FOSTER.

To the Editors of THE LANCET.

SIRS,—Staff-Surgeon Corrie will, I think, obtain a copy of "The London Medical Student" by either advertising in the "Secondhand Books" columns of the *Publishers' Circular* (Sampson Low, Limited), or addressing a post-card to each of the various dealers whose names are given in the list. I saw the book myself only a short time ago, whilst "hunting" for others on a "stall," but I cannot recollect where. It is strange that a new edition of this highly successful, clever, and amusing work has not been issued by some enterprising publisher or other.

I am, Sirs, obediently yours,

Bloomsbury-place, W.C., Oct. 26th, 1889. CHARLES F. RIDEAL.

THE INTERMARRYING OF CONVICTS.

IN Italy, where all "questions" relating to the detention, employment, and disposal of an abnormally numerous convict population may truly be described as "burning," our annotation, which appeared on Aug. 10th, on the above topic has attracted considerable notice. Our attention has just been directed to a recent number of the *Opinione*, the organ of the Italian Right which perpetuates the liberal traditions of Cavour, and which translates the annotation *in extenso*, and introduces it with the following observations:—"Readers of the *Opinione* are probably aware how the French Republic has constituted itself the apostle of marriages between felons, and it may not be without interest to them to know the comments made on this wild legislative measure by the most authoritative of the English medical journals, which also ranks among the most celebrated of the two hemispheres—THE LANCET. It is superfluous to state that everyone even moderately schooled in medicine, or in any degree acquainted with the laws of atavism, which mould in their evolution with equal potentiality the cellule and the moral life, must, whatever his theory of those laws, acquiesce unreservedly in the pointed remarks of the most accredited British journal" (*l' accreditatissimo giornale Britannico*). Then follows a summary of the official *apologia* of the French Government in its new legislative departure, and the translation of the reply which "il celebre periodico medico inglese" makes to it. To the *Opinione's* article are appended the initials of a distinguished Venetian consultant, who effectively reinforces the doctrine of which Dr. Lombroso in Italy (like Sir James Coxe and Dr. Bruce Thomson before him) is now the most vigorous vindicator, as to the best mode of diminishing crime.

Veritas.—The passage complained of in the obituary notice of Dr. Habershon, published by us last week, was not intended to present a partisan view of the merits of the dispute at Guy's Hospital, but simply to record the circumstances which led to the resignation by Dr. Habershon of the physicianship of that institution.

Mr. Montagu Palmer.—The "bother" complained of is great, but we should not advise making it a subject of newspaper complaint. The remedy would be worse than the disease.

Dr. Geo. B. Beale.—THE LANCET, Sept. 14th, 1889.

THE EXAMINATION FOR THE MEMBERSHIP OF THE ROYAL COLLEGE OF SURGEONS.

To the Editors of THE LANCET.

SIRS,—Kindly permit me to make some remarks on behalf of intending candidates for the M.R.C.S.

I was a candidate at the recent examination for the M.R.C.S., but I was referred for six months. Why? At both tables I was questioned on Pott's disease in connexion with the section on pathological anatomy. The examiners appeared satisfied with my answering on the nature of the disease and on the mode of formation of a psoas abscess. But when I was asked the treatment of a psoas abscess, the candidate disagreed with the examiner, unfortunately, on this point. I have altogether spent about six years in the surgical wards under the most celebrated surgeons of the day, and I have consulted most handbooks, and compared my teaching carefully with these handbooks. I had no hesitation whatever in saying that I would open a psoas abscess; the patient would be quickly relieved, and if Listerism were carefully carried out no evil result would supervene. But "No," said the examiner "leave it; the liquid will become absorbed, and only a slight hard swelling remain." I was thunderstruck, and could not further proceed with my examination. I was questioned on the direction of Colles' fracture in connexion with the clinical part of my examination. The examiner disagreed with me when I said it was usually transverse; but, strange enough, at my pathological examination I thought I had better hush my conscience on being asked the direction of this fracture, supposing that English people always had their bones broken obliquely, and thus I answered, whereupon the examiner handed me a specimen, which, of course, was transverse.

If I did not suppose that I am trespassing too far, I could cite some more examples like those I have quoted. I think a candidate should get full credit for his answer, provided that answer comes from good authority, even though it be not consistent with the views or whims of the examiner. At all events, it would be to the advantage of candidates if the examiners for the M.R.C.S. could agree among themselves; for then the candidates would have more faith in them, and would consider them greater authorities than were their teachers.

I am, Sirs, yours truly,

Oct. 28th, 1889. PSOAS.

PHARMACEUTICAL SOCIETY OF GREAT BRITAIN.

To the Editors of THE LANCET.

SIRS,—I note that in your annotation, "Remarkable Suicide with Prussic Acid," you speak of Mr. Pollard as an Associate of this Society. This is incorrect, as he is not connected with the Society.

I am Sirs, yours truly,

Oct. 29th, 1889. RICHARD BREMRIDGE, Registrar.

TELEGRAPHIC ADDRESSES IN THE MEDICAL DIRECTORY.

To the Editors of THE LANCET.

SIRS,—Your correspondent in last week's issue had no authority for the assumption that unregistered telegraphic addresses would be inserted in the Medical Directory. Only registered addresses are inserted, and we require the certificate of registration to be forwarded, with stamped directed envelope for its return.

We are, Sirs, yours faithfully,

The Medical Directory Office, 11, Burlington-street, W., Oct. 29th, 1889. THE EDITORS.

CIRCUMCISION.

To the Editors of THE LANCET.

SIRS,—Your correspondent, Mr. Lancelot Newton, will find a description of the operations for restoring the prepuce in Celsus, book vii., cap. xxv. The second one was that used for the purpose referred to.

I am, Sirs, yours obediently,

Wimpole-street, W., Oct. 30th, 1889. WALTER G. SPENCER.

ERRATUM.—By a typographical error in the notice last week of Dr. Ricord he is represented as having returned to Paris from the provinces in 1888; it should have been *1828*.

An Address
ON
A NEW ANTISEPTIC DRESSING.

Delivered before the Medical Society of London, Nov. 4th, 1889,

BY SIR JOSEPH LISTER, BART., F.R.S.,
PROFESSOR OF CLINICAL SURGERY IN KING'S COLLEGE.

MR. PRESIDENT AND GENTLEMEN,—When I last had the honour, five years ago, of addressing this Society at the request of its President, I brought before you an attempt I had made to utilise the powerful antiseptic properties of corrosive sublimate without the great disadvantages attendant upon its highly irritating qualities. I had ascertained that when corrosive sublimate precipitates albumen the precipitate is not, as had been generally supposed, an albuminate of mercury—that is to say, a combination of albumen as an acid with mercury as a base; in other words, that the albumen does not displace the chloride from its combination, but that the bichloride of mercury retains its properties intact, the albumen being loosely associated with it, in a species of solid solution, if I may so speak.

Further, I had found that this precipitate, even after drying, is capable of being dissolved in the serum of the blood, and that the solution in blood serum is powerfully antiseptic while not irritating. I proposed and brought before you a new dressing in the shape of what was termed the sero-sublimate gauze, charged with a solution of corrosive sublimate in the serum of the blood. This gauze gave very satisfactory results, both in my own hands and in those of surgeons in places so far distant as Poland and Spain. Nevertheless, it was not all that could be desired by any means; it was somewhat harsh mechanically; it was not very absorbent (a serious defect), and one of the materials of which it was made (the serum of horse's blood) was not always easily obtainable. I was, therefore, well disposed to look for something superior.

A few weeks after that communication was made to the Society, a firm of manufacturing chemists, Messrs. Gibbs, Cuxson, and Co., wrote to me saying that they had found that if chloride of ammonium or sal ammoniac in quantity equal to one-fifth part of the weight of the bichloride of mercury was added to the mixture of bichloride of mercury and blood serum, the result was a much more fluid preparation than I had obtained. If I used a preparation of one part of bichloride of mercury to 100 of blood serum, I got a thick liquid somewhat difficult to diffuse in gauze. They therefore suggested that by adding sal ammoniac in that proportion I should get a much more workable arrangement. On consulting chemical works I found that one-fifth of sal ammoniac was exactly sufficient to produce with bichloride of mercury the salt long known to chemists as sal alembroth, a double salt of bichloride of mercury and chloride of ammonium. I naturally wished to ascertain whether this addition of sal ammoniac would impair or even destroy the antiseptic properties of the bichloride of mercury. I therefore made experiments on the point, and I found that the sal ammoniac associated in the form of a double salt with the bichloride of mercury did not by any means impair its antiseptic properties; on the contrary, it improved them, so far at least as concerned that which we have to deal with as surgeons, an albuminous fluid like the serum of the blood. Sal alembroth and bichloride of mercury proved to be exactly equivalent weight for weight as antiseptics in such a fluid. Each had to be used in normal serum of specific gravity of about 1025 in the proportion of about $\frac{1}{1000}$ in order to prevent altogether the development of micro-organisms. Those who are acquainted with Koch's researches will consider this a very high proportion. Koch has shown that in a solution destitute of albumen $\frac{1}{100000}$th part of bichloride of mercury is sufficient to prevent the development of organisms; but when we have albumen present in the solution the case becomes altogether altered. Albumen interferes with the antiseptic action of corrosive sublimate, and thus in serum of the blood of specific gravity 1025 we require, as I have already said, as large a proportion as about $\frac{1}{1000}$ instead of $\frac{1}{100000}$.

When the albumen is small in amount, less corrosive sublimate proves efficient. Thus, in a case of spermatocele, where the specific gravity of the fluid was exceedingly low—only 1007—I found that $\frac{1}{10000}$, just intermediate between the proportions required for blood serum and water, was efficacious. On the other hand, when blood-corpuscles are mixed with the serum in the same amount as in the circulating blood, making the albuminoid substances much more abundant than in serum, we require proportionately more of the corrosive sublimate; at least 1 to 500 is required for the purpose of preventing development. This is a most important consideration after an operation. In the first twenty-four hours the discharge contains a large amount of blood-corpuscles as well as the serum; whilst, at the same time, it is the most copious—more copious than it will be in any subsequent day, provided all goes well aseptically. It is, therefore, an exceedingly serious consideration that in the first twenty-four hours we have a discharge which in both these respects tests our antiseptic more severely than it will ever be tested again, both from its abundance and from its quality. Still, the sal alembroth, whether used with blood serum or with a normal mixture of serum and corpuscles such as that obtained by whipping the blood of the ox so as to get rid of the fibrin, proved equivalent antiseptically to bichloride of mercury.

I may perhaps say in a few words how the experiments were conducted. For the purpose of ascertaining whether a given antiseptic can or cannot prevent development of organisms, a very simple mode of experimentation suffices. What we have to do is to ascertain whether it is *inhibitory*, not whether it is *germicidal*. The only special apparatus required for such experiments is a warm chamber which can be kept pretty constantly about the temperature of the human blood. Beyond this a few stoppered bottles, with well-fitting stoppers—perhaps half-ounce stoppered bottles—are really all that is required. Into a series of such bottles serum of the blood, to the amount, say, of 150 grains, containing solutions of the antiseptic of different strengths, is introduced. These are all inoculated by means of a small syringe pipette with the same quantity, say, $\frac{1}{10}$th of a minim, of some potently septic liquid, such as blood serum in a state of advancing putrefaction. The bottles are placed in the incubator, and then, if development takes place, that is evidence that in the bottle in which it occurs such proportion of the antiseptic as that bottle contains is inadequate; if no development occurs, we have proof of antiseptic efficacy. The transparency of the serum permits a recognition of the development of the organisms, which invariably causes opacity. If we have no change in this respect, if the serum maintains its transparency, at the same time keeping its odour unimpaired, and, further, if microscopic examination of any little sediment there may be shows that it contains no organisms, we have clear evidence that the antiseptic in the proportion concerned has proved efficacious.

Now if the sal alembroth was equivalent to the bichloride of mercury, weight for weight, that shows that the sal alembroth was really more efficacious as regards the quantity of bichloride of mercury it contained. The bichloride of mercury having the sal alembroth added to it, and also water in the double salt that is formed, is increased in atomic weight very considerably; and therefore if an equal weight of alembroth is equivalent in antiseptic action to bichloride of mercury, that shows that the bichloride of mercury is made more efficacious in the blood serum by the addition of the chloride of ammonium. The chloride of ammonium in combination protects the bichloride of mercury, so to speak, to a certain extent, from the interfering influence of the albumen.

At the same time, the sal alembroth proved much less irritating than bichloride of mercury. Experimenting on my own skin, I ascertained that it has certainly not half the irritating property of corrosive sublimate. The chloride of ammonium attached to the bichloride of mercury, while it protects the bichloride in some degree from the influence of albumen interfering with its antiseptic operation, prevents it also from acting so powerfully on the human skin. And thus the union of sal ammoniac with corrosive sublimate had the double advantage of rendering it both more efficacious antiseptically and much less irritating.

Hence I was at first much pleased with sal alembroth. But it soon appeared that there were certain disadvantages attending it. These depend very much upon its excessive solubility. It is essential for a satisfactory antiseptic dressing that the antiseptic should not be readily washed out of it by the discharge. Sal alembroth is so exceedingly soluble that it is washed out with the greatest ease; thus we were always, even if we used large masses of sal-alembroth gauze, in fear that when the discharge was copious the antiseptic would disappear, say, within the first twenty-four hours, and then the septic mischief would have an opportunity to enter. There was another disadvantage from this great solubility. When the discharge entered a mass of the sal-alembroth dressing it dissolved out the alembroth from it, passed into another part of the dressing, and there took up another portion of the sal alembroth, and so went on from part to part of the dressing, until if the discharge was copious and the dressing large, as it must be when the discharge is copious, before the discharge got to the edge of such a dressing it became so concentrated a solution of the sal alembroth as to be highly irritating. We have seen, for instance, after the removal of the mamma, when the first dressing was changed on the following day, that there has been over the scapula and the neighbourhood a huge blister. No doubt that was only a temporary inconvenience. We never had the discharge again so great as in the first twenty-four hours, but still it was a great inconvenience.

Such being the disadvantages of sal-alembroth dressing, I was disposed to seek for something better. I may say that I myself have never published anything in favour of sal-alembroth dressings; I have never been satisfied with them. It has leaked out that I have used them, and they have come into extensive employment, but never with my published sanction.

In the course of the following year I made various experiments in the hope of rendering sal alembroth more useful in different ways, with which I need not trouble you, but without much success. In February, 1886, my attention was drawn by Mr. Martindale, of New Cavendish-street, to cyanide of mercury as possibly a valuable antiseptic, and, if so, having this advantage, that it did not coagulate albumen. I therefore proceeded to make experiments with cyanide of mercury, and I found, indeed, that in inhibitory power it was remarkably efficacious. I have said that with blood serum sal alembroth or bichloride of mercury is required in about $\frac{1}{10000}$th part. I found that the cyanide of mercury kept blood serum with only $\frac{1}{10000}$th part perfectly free from organic development, in spite of inoculation with potent septic fluid, for a month, when the experiment ended. I may remark that we have in the cyanide of mercury a striking instance of the discordance that there may be between inhibitory power and germicidal power in an antiseptic. In inhibitory power the cyanide of mercury is, as we have seen, exceedingly high; but in germicidal power it turns out to be very low. Mr. Cheyne has made experiments for me, which have shown that even $\frac{1}{1000}$th part in water is incapable of destroying the germs of bacteria. Still, the inhibitory property of cyanide of mercury was a most important point if in other respects the salt were not disadvantageous; but, unfortunately, it proved to be so highly irritating that the greater irritating property of the cyanide of mercury more than counterbalanced its superior inhibitory power. It naturally occurred to me that the cyanide of mercury might perhaps combine with some other cyanide and form a double salt, having advantages corresponding with those presented by sal alembroth as compared with bichloride of mercury. I tried the soluble double cyanide of mercury and potassium, but found it quite too irritating. I here again consulted Mr. Martindale, and he mentioned to me that in "Watts's Dictionary of Chemistry" it is stated that a double cyanide of mercury and zinc of very slight solubility may be formed by mixing together a solution of the double cyanide of mercury and potassium with a soluble salt of zinc, the zinc taking the place of potassium. I therefore obtained some of this material, and proceeded to make experiments on it. I found, in the first place, that it was quite insoluble in water. This seemed at first extremely unpromising. It was soluble in about 150 parts of glycerine, but insoluble in water. I found, however, that it was soluble in about 3000 parts of blood serum, and therefore it was possible that it might work antiseptically. I made experiments to ascertain whether such was the case or not, and I found that this zinco-cyanide of mercury, as we may call it, had really most important antiseptic properties; that in the proportion of $\frac{1}{10000}$th part it kept blood serum perfectly free from the development of organisms for eighteen days, in spite of potent septic inoculation.

I then tried experiments with serum and blood-corpuscles as presented in the whipped blood of the ox. On instituting comparative experiments between sal alembroth, cyanide of mercury, and this double cyanide, I found that with the alembroth all proportions lower than $\frac{1}{100}$th putrefied within twenty-four hours after septic inoculation, while with the cyanide of mercury $\frac{1}{800}$th part sufficed to preserve the serum and corpuscles from putrefaction. At the same time, with the double cyanide I was much surprised and much pleased to find that $\frac{1}{1600}$th, half as little again, was sufficient to keep the mixture of serum and corpuscles permanently free from putrefaction. It may be said that the absence of putrefactive odour is but a rude test. There may be organisms developed without any putrefactive odour being present; that is perfectly true. At the same time, if in a given experiment we find that with one agent putrefaction occurs within twenty-four hours with $\frac{1}{100}$th part, while with another salt there is no putrefactive odour after the lapse of weeks with $\frac{1}{1600}$th part, we have pretty conclusive evidence that, so far as the mixture of corpuscles and serum is concerned, you have a more efficacious antiseptic in the latter. I therefore proceeded to prepare dressings of this new substance, diffusing it—for it is an exceedingly fine powder—in water with a little glycerine added to fix it, to prevent it from dusting out. If you simply diffuse it in water, and pass gauze through it, with nothing more than the water, the result is that you have gauze which, with the slightest touch, gives out the double cyanide in a cloud of dust, which produces not only inefficacy of your dressing by loss of the proper proportion of the substance, but becomes in the highest degree irritating to the nostrils of those who are near. A little glycerine, however, prevented the double cyanide from thus dusting out. I proceeded to try it in practice. I confess I did not dare to use it—considering its very slight solubility in serum—unmixed, and I associated with it some of the very soluble cyanide of mercury; and with this cyanide gauze we tried various experiments in the way of dressing, and got some admirable results. But then, on the other hand, there were disappointments. We found, for one thing, now and then very troublesome pustules as the result of a peculiar kind of irritation. Another disadvantage was that occasionally we got suppurations, coming on at a late period in the case, such as we had never been accustomed to with our carbolic dressings. A case might go on perfectly well for, say, ten days, and then suppuration might occur about a stitch track and spread perhaps further; and sometimes the healing of cases was greatly protracted by this late suppuration. In consequence of these two circumstances I gave up the use for the time being of this material.

I then directed my attention to biniodide of mercury, which has been highly spoken of for its antiseptic powers, and which has the advantage over alembroth of being comparatively little soluble either in water or in serum. I found that the iodide of mercury gauze answered our purpose very well so far as its antiseptic properties were concerned, but that it had the great disadvantage of producing irritation, which it was extremely difficult to control. In order to control it, we interposed between the iodide of mercury gauze and the skin unprepared gauze, except in so far as it was steeped in a weak solution of bichloride of mercury (1 to 4000). But we found that different skins differed greatly in liability to this irritation. The iodide of mercury, which is so very slightly soluble, as you know, in water, is much more soluble in serum, and the solution in blood serum becomes irritating. In consequence of this, we had the same disadvantages from irritation as we had with the alembroth; and although, as in the case of the alembroth, this was only a transient inconvenience, I became dissatisfied with the iodide of mercury gauze. There was, however, one point of considerable interest, both theoretically and (as it turned out afterwards) practically, which we found in this investigation with the iodide of mercury. If we simply charged with iodide of mercury, say, from a solution in spirit of wine, and then applied the gauze so prepared, we found that the particles of iodide of mercury tended to gravitate down towards the skin, and there produce the most fearful irritation. It was absolutely necessary that

Digitized by Google

it should be fixed. I tried various means, and among the rest a solution of starch, and then there came out this remarkable fact, that if a solution of starch is used with one of the ingredients employed for forming the biniodide of mercury by mixing a solution of iodide of potassium with solution of bichloride of mercury — if you dissolve the iodide of potassium in a weak solution of starch—the iodide of mercury thus formed in the nascent state associates itself with the starch particles in the most intimate manner, and the starch becomes entirely precipitated along with the iodide of mercury. If you take a drop of the red fluid formed by mixing these two solutions, and place it on a piece of calico, the watery material is absorbed by the calico and passes into the surrounding parts without colouring them, while the red spot with its insoluble iodide remains. If now you take a little iodine water, and apply it to the part of the calico moistened by the fluid that has exuded, you find that the iodine water produces no blue colour of iodide of starch, showing that there is no starch in the fluid that thus oozes out and leaves the iodide of mercury behind; whereas, if you take a solution of starch and apply it as such to a piece of fabric, as far as the fabric becomes moistened so far do you get a blue colour with the iodine. Here we have, as it seems to me, a somewhat analogous case to the so-called albuminate of mercury. We have the starch particles associated with the particles of iodide of mercury; the starch remains as such, the iodide of mercury remains as such, still they are attached to each other. And so the result was that when such a red solution produced by these two liquids was used for charging a gauze, the iodide of mercury was stuck to the gauze by means of the starch, and we had a most satisfactory arrangement in that respect. The iodide of mercury could not be washed out by water, nor did it in the least dust out. The value of this observation with reference to our present subject will appear shortly.

Being dissatisfied with the iodide of mercury, I turned my attention again to the double cyanide of mercury and zinc. Looking back to my notes, I found such evidence of its superior antiseptic properties that I felt that we had deserted this material too readily. In the interval we had had other experience of importance with the alembroth gauze. Occasional late suppurations had at first occurred under its use, just as was the case with the double cyanide gauze. These, however, had ceased to trouble us after my attention had been directed to the expediency of always using mercurial dressings in a moist condition. If they are used dry, the mercurial salt having no volatility, and having no power, therefore, of destroying any micro-organism in contact with it, whether derived from the manufactory or elsewhere, there could be no security that the dressing when applied was free from living organisms. This important object could, however, be infallibly attained if the dressing were used moist with an efficient germicidal solution. I put this idea into practice, and during the two years that have since elapsed we have never on any single occasion had to complain of these late suppurations. Might not the same immunity attend our cyanide gauze if we adopted with it the same expedient?

The other objection to this double cyanide gauze had been the irritation which it occasioned. Might not this have been due to the simple cyanide, which, as I have said, I used along with the double cyanide? The simple cyanide is highly irritating, and, just as with the sal alembroth, being freely soluble, it can be taken up by successive portions of discharge, and, when the discharge is free, may come to be in so strong a solution as to irritate. On the other hand, experiments on my own person had shown that the powder of the double cyanide might be kept applied to the skin for an indefinite time, whether moistened with water or with blood, without occasioning any irritation whatever. If this was really the explanation, and if, as our experiments seemed to indicate, the double cyanide could be trusted of itself, we might easily get rid of all irritation by using a double cyanide dressing moistened with a weak solution of bichloride, say, 1 to 4000, which, while it is securely germicidal, can never irritate. But here arose a new difficulty. I have told you that when we tried this double cyanide in a gauze at first, in order to prevent the dusting out, with its great inconveniences, we used glycerine; but if we were to moisten the gauze with 1 to 4000 solution of corrosive sublimate, we should run great risk of washing out the glycerine, and then the double cyanide would be free to dust out on drying. And, besides that, it must be admitted that the glycerine arrangement was not a good one, independently of that consideration, inasmuch as when the discharges flowed into the gauze they would wash away the glycerine, and then the double cyanide might be washed out also, and so fail in one of the most important requisites of an efficient antiseptic dressing—the storage of the antiseptic in the dressing in spite of the discharge. How was this difficulty to be overcome?

Now came to our aid our experience with the iodide of mercury and the starch. Might it be that the particles of the double cyanide would attract starch as those of the iodide had done? It did not seem very likely, seeing that cyanogen is not known to have the special affinity for starch that iodine has. Still, I thought I would try the experiment. I prepared the double cyanide by mixing a solution of the double cyanide of mercury and potassium with a solution of sulphate of zinc. I tried this with one of the ingredients dissolved in a starchy solution, and, to my great satisfaction, I found that the precipitated double cyanide left a supernatant liquor almost absolutely free from starch, and that the particles which thus fell, the double cyanide with the starch associated, fixed themselves to a gauze in such a way that it did not in the least dust when dry. Not only so, but immediately after being charged with the precipitate diffused in water it might be washed in the wet state without the double cyanide being washed out of it, so closely did the starchy particles stick the double cyanide to the fabric. It is of great importance that in some way or other the double cyanide should be washed, because at the same time that an insoluble double cyanide is formed there are produced other double cyanides which are soluble, and which are in the highest degree irritating; they must be washed out.

Well, I thought I had thus attained my object, and that by mixing starch with one of the two solutions necessary for forming this double cyanide and allowing the precipitate to deposit itself, then pouring in more water, and, after precipitation, decanting and repeating the process another time, so as to get rid of all the irritating soluble salts, and then diffusing the precipitate through a gauze, I should have all that I desired. But when I tried to get this done by a manufacturer I found that I got blundering after blundering in such a way as to make the thing practically hopeless. There was nothing for it but in some way or other to get the double cyanide from the chemist as a definite article, and then in some way devise a means of fixing that powder of the double cyanide to the fabric. I therefore naturally tried whether a solution of starch would answer this purpose, whether the starchy particles would associate themselves with the double cyanide particles, not only in the nascent state, which we had before tried, but also when the already formed double cyanide was mixed with the starchy solution. I found that it did so; that when a starchy solution was stirred up with the double cyanide in the proportion of one part of starch to two of cyanide, the starch was almost all precipitated, and the precipitate so formed adhered to the gauze in the most satisfactory manner.

But, though its adhesion was satisfactory enough, it turned out that the precipitate thus formed aggregated into a tenacious mass, which could not be diffused uniformly through the gauze, and here I was again at fault. This difficulty was overcome by first charging the gauze with the double cyanide powder diffused in water, and then transferring it to a starchy bath. This at once fixed the cyanide in the gauze; and, whereas, before it was placed in the starchy bath, the slightest squeeze made a milky fluid exude, no sooner had it been well penetrated by the starchy liquid than you might squeeze it as you pleased, and nothing came out but a clear fluid. I was much pleased with this, and it is in this way that I have prepared the gauze that I have used for the last twelve months, both in the hospital and in private practice. Still, this method had its disadvantages. When the gauze had been passed through the fluid in which the double cyanide had been diffused without any starch, it required very tender handling. If you gave it a squeeze, out came a quantity of double cyanide; and it was plain that, although one might do it oneself satisfactorily, if we trusted to the manufacturers there would be an utter uncertainty as to what quantity of material might ultimately remain in the gauze.

Only lately has this difficulty been surmounted. It occurred to me that perhaps if the starch were first blended with

Digitized by Google

the double cyanide and then dried and reduced to powder, if water were afterwards added to this dried dissolved starch associated with the cyanide, there might not be the same tendency to lumpiness and difficulty of diffusion. I found that the process did not answer quite as I hoped in the first instance, in this respect; that the dried starch and double cyanide were extremely difficult to scrape off from any plate on which they were put to dry, and also very difficult to pound up and to diffuse for charging the gauze. But I got rid of these inconveniences by means of sulphate of potash, used for the same reason as in the preparation of Dover's powder—viz. that it is an inert substance, but with sharp, gritty particles. Mixing a pretty strong solution of starch with the double cyanide powder, and adding to this a quantity of pounded sulphate of potash, the result is that you get a material which, after drying, is easily scraped off by the manufacturer, and easily reduced by him to an impalpable powder, which is then readily diffused in water, and makes a perfectly uniform gauze; being mixed in large quantity with water in order to charge the gauze, the sulphate of potash is practically got rid of, and if any of it remains it does no harm, because it is inert. Thus we have the means of easily charging fabrics with this double cyanide.

I have spoken of diffusing this preparation in water, but in reality we employ for this purpose the 1 to 4000 solution of bichloride of mercury, which fortunately does not in any way interfere with the process. I may remark that the double cyanide, like the simple cyanide of mercury, though very efficient as an inhibitor, cannot be trusted as a germicide. There are different ways in which absorbent gauze such as this may be charged. One is to pass it folded in about sixteen layers through a trough, such as the one before me, which I have myself used, having a bar near the bottom to ensure the gauze being kept well under the liquid. It is then, as soon as you please, squeezed to press out superfluous liquid, and then, if wanted for immediate use, a simple way is to place the masses of gauze—say, six-yard pieces—in a folded sheet, turn the folded sheet over them, and roll it up. The folded sheet then absorbs the still redundant liquid, and you have moist gauze ready for use in five minutes. For the use of the ordinary surgeon it will probably be best to have the gauze dried, on the understanding that it is again moistened with 1 to 4000 sublimate solution before being used. Here is a sample of the gauze in the dry state, which, you see, does not give off dust even when freely handled.

Other articles may be charged as well as gauze with this substance. The double cyanide being perfectly unirritating in its own substance, there is no objection to having an excess of it. If you take, therefore, some of the preparation and stir it up with 1 to 4000 sublimate lotion, so as to produce an opaque liquid, and put linen rags into it, and then place them in a folded towel to take out the excess of liquid, you have your dressing ready prepared then and there. It can thus be very easily worked on an emergency.

We have seen that the double cyanide requires about 3000 parts of blood serum to dissolve it. If, therefore, it is present in a gauze in the proportion of about 3 per cent., you will easily understand that blood serum may soak through such a gauze time after time without washing the ingredient all out; so that it is a material which is admirably stored up in the dressing. That is one of its three great advantages, the others being that, while trustworthy as an antiseptic, it is completely unirritating. In actual practice the few layers placed next to the wound are washed in a solution of carbolic acid 1 to 20; this washes out the corrosive sublimate, which, though present in small amount, might irritate the wound to some extent. The carbolic acid soon flies off, and there is left in the application next the wound merely the unirritating double cyanide, and under this we find that not only do wounds, the edges of which are brought accurately together, unite beautifully by first intention, but even granulating sores heal by the gradual process of cicatrisation from the edges—heal by scabbing in a way that we have never seen so satisfactory under any other dressing.

Having satisfied myself that this was really a useful material, I proceeded to request a manufacturing chemist to provide it for me on a large scale. Messrs. Morson and Son, of Southampton-row, kindly undertook to do this, and I have to thank them for the great pains they have taken in carrying out experiments on this subject at my suggestion. Their manager, Mr. Taubman, soon informed me that in his opinion there was exceedingly little mercury in this so-called double cyanide of mercury and zinc. Very little mercury could be got from it on testing in comparison with what would be obtained if it were a true double salt. He asked if I was sure that the cyanide of zinc was not, after all, the thing that was efficacious? Was the idea of the double cyanide altogether a delusion? I need not say how much pleased I should have been if such had been the case—if we could have had the cyanide of zinc without any poisonous mercury in it as an antiseptic. The cyanide of zinc was a perfectly definite compound, there could be no mistake about it. I proceeded to make experiments, and I found, indeed, that cyanide of zinc had antiseptic properties. I made, for instance, experiments of this kind: I took a piece of glass tube like that which I hold in my hand, and packed it in two inches of its length with a piece of gauze charged with cyanide of zinc only, and then, holding it vertically, poured serum of horse's blood into it till the gauze was fully moistened; and then poured more in, till a quantity dropped out from the lower end equal to that which had produced saturation, the upper part of the gauze being thus thoroughly washed with the serum.

I then inoculated the top of the gauze with a potent septic drop. I had another such tube packed with gauze that had no cyanide of zinc in it, and I inoculated that in the same way after pouring serum upon it. I then put each into a well-fitting stoppered bottle, so as to prevent any evaporation, and placed them in the incubator. At the end of four days I opened the two bottles. That which contained the gauze without the cyanide of zinc stank, and, on taking portions of the gauze from either one end or the other, squeezing them and examining under the microscope the fluid that escaped, there were seen teeming multitudes of bacteria of various sorts. The bottle with the cyanide of zinc gauze, on the other hand, had a pure odour of hydrocyanic acid, which this gauze always has when moist. I then examined drops squeezed from both ends, and I found no bacteria in the clear serum that was pressed out, not only from the lower end, but even from the upper end, in the immediate vicinity of the inoculating drop, and where the gauze had been drenched repeatedly with the serum.

Now that, so far, is a result that no other antiseptic had ever given me. Take iodide of mercury, for example. Comparatively insoluble as it is, if you pour blood serum upon it in such profusion you wash the iodide of mercury out, and if you inoculate septically the part so washed you induce bacteric development. The test applied was, of course, an extremely severe one. In actual surgical practice the discharge which pours into the dressing is pure to begin with, supposing the wound to be aseptic at the outset. The septic agency only acts from without where the dressing has not been washed by the discharge, and in a far milder form than here, where a potent septic drop was used. Thus we had clear evidence that the cyanide of zinc really is an antiseptic. On the other hand, it turned out to be not so powerful antiseptically as our double cyanide so-called. In order to compare the two salts I made another experiment similar to that last described. I packed three pieces of glass tube with gauze in two inches of their length, one of the gauzes being charged with cyanide of zinc, and another with the so-called double cyanide (neither of these gauzes having been treated with solution of bichloride of mercury), while the third gauze was unprepared. Serum of horse's blood was poured into the upper end of each vertically-held tube till it thoroughly soaked the mass of gauze, after which each gauze was inoculated septically at the centre of its upper end. The tubes were then placed vertically in stoppered bottles in the incubator. It happened that in the septic liquid used for the inoculation that I used there was, among other organisms, a species of streptococcus which had a remarkable power of producing an acid fermentation in blood serum. After four days I proceeded to examined the contents of the three tubes. In the unprepared gauze there was utter putrefaction. In the gauze prepared with cyanide of zinc only, no putrefaction had taken place, but acid fermentation had occurred: both at the upper and lower end of the gauze litmus paper was reddened on application to the serum. In the putrid gauze turmeric paper was most intensely reddened, much more so than by normal blood serum, an alkaline fermentation having occurred there. On the other hand, with the gauze that contained the double cyanide, with mercury as well as zinc, both at the upper and lower end the turmeric paper was reddened exactly as it was by

Digitized by Google

the normal blood serum. This state of things continued the next day; but on the following day, six days after the commencement of the experiment, I found that at the upper end, in the vicinity of the inoculated spot, this double cyanide gauze purpled litmus, while at the lower end it still reddened turmeric. At the end of seven days the same condition persisted. After eight days, however, both the upper and lower end of the gauze purpled litmus. This peculiar septic organism, with the power of producing acid fermentation in serum, had gradually worked its way, in spite even of the cyanide of zinc and mercury; but the cyanide of zinc and mercury, you observe, had been much more efficacious than the cyanide of zinc alone. The cyanide of zinc had prevented the development of organisms that produced putrefaction, and only permitted the development of the coccus that produced acid fermentation. Cyanide of zinc and mercury had for several days prevented all development. This was proof, therefore, that the mercurial element in our compound was valuable, and that we could not dispense with it.

It may be thought an unsatisfactory thing that there should have been any organism able to work its way thus through a gauze charged with our antiseptic. But I may remark, in the first place, that, as above stated, we tested the material exceedingly severely; in the second place, that it was a long while before the organism penetrated the gauze even for a short distance; and, in the third place, that penetration of micro-organisms through such a dressing into wounds does not seem to occur in practice, seeing that in the year during which I have used this antiseptic in my surgical work at King's College Hospital we have had no single instance in which we have had any reason to suspect septic change in the deeper parts of our dressing; we have had no instance in which deep-seated suppuration has occurred in an operation wound made through unbroken integument. If we have had any pus at all in such cases, it has been from the surfaces exposed between stitches or at situations where drainage-tubes have been inserted, where what I have termed antiseptic suppuration has occasionally shown itself, and even this in very slight degree. Such being the case, I feel not only permitted, but bound to bring this material under the notice of my professional brethren.

As to the composition of this so-called double salt, it is for the present uncertain. This much is already established: that the cyanide of mercury is in very much smaller proportion to the cyanide of zinc than "Watts's Dictionary" would lead us to expect from a true double salt. But what the precise composition of the salt is we do not yet know. I am having it investigated by the Pharmaceutical Society, who have kindly undertaken the work.

There is another use for this material besides the charging of dressings. The powder moistened with a weak solution of corrosive sublimate may be rubbed into hairy parts, when it will convert the hairs into an antiseptic dressing. Not long ago a medical friend of mine brought his wife to me with no less than seven sebaceous cysts in the scalp, requesting me to remove them. Having washed the hair with 1 to 20 carbolic acid solution, I simply passed a comb over each tumour in the line where I was about to transfix without shaving at all; and, after taking out the cysts, rubbed in some of the moistened powder into the hair in the vicinity. I then applied a dressing of cyanide gauze, and I was glad to learn that all the seven wounds had healed without disturbance.

We have now in the hospital a case of psoas abscess, shown to be of spinal origin, not only by the history of the case and the symptoms, but by the discharge of a portion of bone with the pus. That case is pursuing a course which, allow me to say, psoas abscesses will pursue in the great majority of cases, if the surgeon uses a trustworthy antiseptic, and takes the same pains with dressing to the last as at the outset; that is, he will find his trouble rewarded by the complete cure of these formerly incurable cases. I say this because I grieve to think that psoas and lumbar abscesses still seem to be regarded as hopeless affairs by many surgeons. In this man's case the temperature has never been affected in the least; he has put on flesh rapidly; the discharge, after the purulent and curdy matter that existed originally in the abscess was got rid of, has been of a serous character, and is in small and diminishing quantity. But the opening made for the discharge is in the vicinity of the pubes, and the pubic hairs used, under such circumstances, to be a constant source of anxiety to us unless frequently shaved away. Here we rub in at each dressing a little of the moistened cyanide, and convert the hairs into an antiseptic application.

I will not at present enter into the details of the preparation of this material; these will be supplied in a note on a future occasion.[1]

The sketch which I have given you of this investigation, though it has, I fear, wearied you, conveys but a small idea of the toil it has involved. There are those who still believe that the use of antiseptic substances in surgical practice is always useless, if not injurious. The germ theory of septic diseases is indeed now happily established incontrovertibly. All now admit that septic mischief in our wounds depends upon the development of micro-organisms in them derived from without. But the gentlemen to whom I refer are, more or less logically, disposed to trust everything to the antiseptic powers of the human tissues.

I believe I happened to be the first to direct attention to the antiseptic agency of living structures, and there is, perhaps, no one who attaches greater importance to it than I do. Without it, surgery in former days would have been absolutely impossible. Still, I know too well from experience that it cannot always be trusted, and that the use of antiseptic adjutants is in the highest degree important; and I have the satisfaction of knowing that there is among you a constantly increasing number who, when they have operated on an unbroken skin, with a fair field around for the application of their dressings, if they see septic inflammation occurring in the wound with its attendant dangers, know that it is their fault or the fault of the antiseptic appliances at their disposal. To those among you who are impressed with this conviction I offer the dressing which I have described as the most satisfactory that I have hitherto met with; and I venture to hope that you will regard it as a not unwelcome addition to your resources.

OSTEO-ARTHRITIS AS AN IMMEDIATE SEQUEL OF RHEUMATIC PYREXIA.[2]

BY J. KENT SPENDER, M.D. LOND.,
PHYSICIAN TO THE ROYAL MINERAL WATER HOSPITAL, BATH.

CLINICAL observation has established a pathological connexion of great practical interest. It has been long known that chronic rheumatism and gout may prepare the way for osteo-arthritis by lowering the textural force of the joint structures, and thus leading to morbid change of a degenerative kind. In people of the so-called tubercular diathesis, or who have near kinsfolk distinctly "consumptive," repeated rheumatic attacks may beget a condition commonly called *rheumatoidal;* and this, again, may gradually pass into the more complete and incurable state which enjoys the official title of Osteo-arthritis.

This clinical doctrine being fully recognised, the precise point of this paper may be formulated as follows:—A man or woman in early middle life has two or three attacks of acute rheumatism close together, affecting (perhaps) knees, elbows, or wrists; he is more or less in bed for several months; the pyrexia is rarely higher than subacute; and there are periods of quiescence during which he not only feels comparatively well, but really *acts* well in the sense of "muddling about," somewhat crippled it may be, but with a convalescent energy deserving praise. Nevertheless, the patient does not wholly emerge from a quasi-rheumatic condition. And it is of such sufferers that we constantly ask ourselves, especially in our Mineral Water Hospital, *is this case going off rheumatoidally?* is he marching in the direction of osteo-arthritis? An exceedingly practical question. Two groups of clinical phenomena appear to coalesce; the latter looks a mere postscript of the former, continuous in time and quality; in reality it is so different that the treatment calculated to moderate the one may only increase the other. The pyrexia is gone, but the pulse remains quick, or even quicker; the true rheumatic sweating has passed away, but a new type of sweating begins; and we are conscious of a fresh series of clinical phenomena, some of which are a mere continuation of the old (such as pain and enfeeblement of joints), and

[1] This note will appear in our next issue.

others are the commencement of an entirely different order of symptoms.

Now our plea at the outset of this discussion is, that what has been described as acute rheumatoid arthritis has no clinical existence. The state of things so denominated is merely a *rheumatic prodroma of rheumatoid arthritis*, preparing the way and leading on to it in subjects predisposed. There is no such predisposition in the vast majority of cases; rheumatic pyrexia comes and goes, leaving perhaps some trace of medical damage, which is usually quite remediable.[3] But, after coming and going two or three times, the true rheumatism may become something else, not merely something chronic in the room of something acute, but a slow grade of an essentially different arthritic trouble, the steps of sequence to it being caught only by a practised eye. So far as joints are concerned, the transition is probably not marked at all; what was swollen and painful remains swollen and painful; the objective lesson is not easy to read. But we pick up the threads of diagnosis by studying the concurrent facts. The pyrexia is slight, and obeys other laws; pigmentary stains and spots appear, and the neural signs of pain and muscular atrophy possess new significance. The weakness and incapability of movement increase quickly. In doubtful cases the dynamometer should be always used; little impression is made upon it by the palsy-stricken muscles of the hands. But it must be confessed that, through inattention or lack of insight, the clinical condition of the patient may undergo an entire change, without a single note being made of it by anyone.

The therapeutic issue of these considerations is of the highest moment. When the true rheumatic storm has subsided, it is not only injudicious but very hurtful to go on prescribing salicin and the salicylate salts, and potash or soda in any guise. The iodides are equally useless, and perhaps equally injurious. Salicin is bound up with rheumatism by the closest ties; it is one of the magnificent advances of recent years; and so it follows that any arthritic affection which looks like rheumatism suggests a salicin treatment. Or if a distinct gout has preceded the osteo-arthritis, the chance is that colchicum and alkalies are continued. The case is now called "suppressed gout," or "latent gout," or any other dark veil of words which are algebraic signs of what we do not understand. The physician who is blind to what is going on before him had far better leave his patient alone. I cannot speak too strongly of the mischief done by this wrong system of medicine. The drugs thus wrongly given are not "phantom" drugs, idle for good or harm, but agents of positive evil. They lower the nerve tone and impoverish the blood quality; and, worst of all, they occupy that precious time during which the ingravescent osteo-arthritis should be fought with its proper weapons. When the mistake is found out, the sad legend "too late" has to be written. The unhappy patient is a life-long mourner of an irrevocable fate; and the doctor who errs from want of experience has leisure to think over an imperfect diagnosis.

To grasp the point of time when one pathological current stops and another begins is to hold the key of the position. We push aside the so-called specific remedies; we tranquillise the nervous and vaso-motor systems by quinine, belladonna, and strychnine; as soon as possible cod-liver oil and arsenic are brought to bear, to be followed at no long interval by a stable preparation of iron. There must be corresponding changes in the diet, which ought to be rich in nitrogenous and fatty material. And if we have been so unwise as to order alcohol under the poisonous garb of brandy or whisky, we shall now recommend a moderate amount of generous wine—at least four ounces daily of dry old port or of matured burgundy.

And now comes the hygienic and therapeutic touch of the Bath thermal Waters. Let them be used with every care. I am obliged to admit that hydro-therapeutics and shampooing are sometimes overdone. The delicate atrophied creatures who submit to these processes require to have them performed in the gentle manner of reclining baths, quiet douches, and domestic *massage*. Most good is to be expected from our thermal Waters when there is an antecedent history of rheumatism or of gout. In other cases, when osteo-arthritis is distinctly a sign of local or general deterioration, internal medicinal treatment is of at least equal value. One more caution. So-called counter-irritation (with iodine, for example) should never be done *immediately over* an affected joint. Such a process is essentially unscientific, for it creates an artificial excitement and hyperæmia in the very structures which we should try to keep in a quiescent mood.

The accumulation of clinical material at our thermal Spa affords a splendid school of study in osteo-arthritis. The subject is complex, with many bye-paths reaching among the thickets of physiological pathology. A complete scheme of the neurology of osteo-arthritis has yet to be unfolded. The arthritic disease, paradoxical as it sounds, may not be the central lesion at all; it may be only one member of a group of lesions, and not the most important. The writings of Sir Dyce Duckworth and Dr. Ord have contributed much to the solution of our difficulties; and rays of light are coming from many other quarters.

Bath.

[3] The term chronic rheumatic arthritis should be strictly confined to the arthritic lesions produced by true rheumatism; the confusion of our terminology has caused confusion of ideas.

ELEVEN CASES OF INTUBATION IN YOUNG CHILDREN.

By W. H. C. STAVELEY,

HOUSE SURGEON TO THE VICTORIA HOSPITAL FOR CHILDREN, CHELSEA; LATE HOUSE SURGEON TO ST. THOMAS'S HOSPITAL.

IN publishing the following small number of cases, I do not wish to claim that the results are more satisfactory than those of tracheotomy, but having had the opportunity of watching the cases constantly, my object is to bring into prominence the more important events which occurred during the treatment of cases of laryngeal obstruction by intubation. O'Dwyer's instruments were used in all, the size of the tube selected being in accordance with his scale. It will be seen that tracheotomy was resorted to in those cases in which it seemed that an open wound would give better hopes of relief.

CASE 1.—Frances H——, aged thirteen months, was admitted to hospital on Dec. 12th, 1888. Previous history: Patient, who was not completely weaned, was seized with cough on the day previously to admission, and had an attack of dyspnœa during the evening. An emetic was given with partial relief. When admitted at midday her condition was that of a feeble, rickety child, with stridulous breathing, retraction of chest wall, and cyanosis; membrane on both tonsils. Intubation was immediately performed, with complete relief of dyspnœa and retraction. At 4 P.M. the tube was coughed out; she breathed well for one hour, then dyspnœa returned, and at 6 P.M. the tube was replaced with complete relief. Temperature 104·4°.—13th: At 5 A.M. much coughing and slight dyspnœa. The tube was removed, cleaned, and replaced. Breathing was then rapid but easy. Crepitations heard at right base. Temperature 105·4°. Taking food well.—14th: No return of dyspnœa, but sank and died at 2 A.M.—*Necropsy:* Patches of membrane were found the whole length of the respiratory tract. Pneumonia and consolidation of lower lobes of both lungs.—*Remarks:* A feeble child with urgent dyspnœa; the symptoms referable to laryngeal diphtheria completely relieved by intubation.

CASE 2.—Lilian B——, aged four months, was admitted to hospital on Jan. 8th. Previous history: Had been suffering from bronchitis for a month. Croupy cough began on the morning of the day of admission. Much dyspnœa, stridulous cough, and recession of the ribs when admitted. No membrane seen on fauces. Coarse râles heard over both lungs. Temperature 100°.—Jan. 9th: Dyspnœa diminished, but increased during afternoon, with extreme recession of the chest wall. The ordinary emetics failed to induce vomiting, so an O'Dwyer's tube was inserted, but without relieving the symptoms, and was removed after a brief period. Temperature 100°.—11th: Temperature rose to 105°, and the patient died at 6 P.M.—*Necropsy:* Intense congestion of the larynx and treachea, and numerous patches of membrane. Both lungs solid, with acute pneumonia.—*Remarks:* In this case the probabilities of the dyspnœa being due to the condition of the lungs was fully recognised. Intubation was performed more as a means of diagnosis than with any real hope of relieving the symptoms.

CASE 3.—Maud S——, aged two years and two months, was admitted to hospital on Jan. 13th. Previous history: Sick on Jan. 11th, dyspnœa began on the 12th. On admission,

Digitized by Google

at 4 P.M., the patient was suffering from extreme dyspnœa and recession. The fauces were coated with membrane. Temperature 101°. Intubation was performed immediately, with complete relief. She took food freely. At 10 P.M. the tube was coughed out; but she breathed well until 2.30 A.M. on the 14th, when dyspnœa returned, with frequent cough and much mucus. Intubation was again practised, but with very partial relief, so tracheotomy was performed, with marked improvement resulting. Fine crepitations heard in lungs. Temperature 103°.—15th: No return of recession, but she sank and died at 2 A.M.—*Necropsy:* A continuous lining of membrane throughout larynx, trachea, and small bronchi. Lungs collapsed, slight pneumonia. Bronchial glands large and caseous.—*Remarks:* In this case, as in Cases 4 and 8, owing to the presence of much mucus, an O'Dwyer's tube failed to relieve the dyspnœa, so tracheotomy was resorted to, the larger lumen of the tube affording a freer vent.

CASE 4.—Ernest W——, aged sixteen months. Previous history: The patient had been in this hospital since September, 1888, with repeated attacks of broncho-pneumonia.—Jan. 22nd: During early morning the voice was hoarse, and in the afternoon marked stridulous breathing and recession with extreme dyspnœa occurred. No membrane seen on fauces; no enlargement of glands. At 4.30 P.M. an O'Dwyer's tube was inserted, followed by violent coughing and increased recession. The tube was removed, and for a brief period the breathing was easy, but the cough frequent and much mucus. At 5 P.M. the dyspnœa again became urgent, and tracheotomy was performed, small pieces of membrane being removed with a feather. The tracheotomy gave immediate relief, and the patient progressed favourably until the 24th, when he seemed to lose strength, and died on the 25th.—*Necropsy:* No membrane on fauces, but below the level of the vocal cords a continuous lining of tough membrane. Lungs studded with tubercular deposits; bronchial tubes dilated to the size of a goosequill.

CASE 5.—Ellen B——, aged eighteen months, was admitted to hospital on Feb. 13th, 1889. Previous history: Patient had recently recovered from scarlet fever. She seemed feverish, and croupy cough began on the evening prior to admission. When admitted, at 9.30 P.M., there were urgent dyspnœa, cyanosis, and marked retraction. Temperature 101°. Intubation was at once performed, with immediate and complete relief. She took food well during the night, but gradually became weaker, and died at 10 A.M. on the 14th.—*Necropsy:* Extensive deposit of membrane and double early pneumonia.—*Remarks:* The same remarks apply here as in Case 1. No return of dyspnœa, and death occurred from asthenia.

CASE 6.—David H——, aged three years and four months, was admitted to hospital on April 6th, 1889. Previous history: "Feverish attack" on April 1st. Shortness of breath on the 3rd. Had a "choking fit and became livid" on the 6th. When admitted, at 10 P.M., he was suffering from cyanosis, marked dyspnœa and retraction, and crowing inspiration. Intubation was performed immediately, with marked relief. Fell asleep soon afterwards. Temperature 100 8°.—April 7th: Slept quietly all night. Fit of coughing at 9 40 A.M. and the tube was thrown out. Continued to breathe quite easily for two hours, when the dyspnœa returned, and the tube was replaced. In introducing the tube, a cylindrical cast of the trachea was found in the throat and removed. Temperature 101°.—8th: Tube removed at 10 A.M.; the cough continued croupy for some days, but intubation was not again required.—May 2nd: Discharged well.—*Remarks:* Intubation was performed twice. The tube was *in situ* thirty-four hours altogether, with an interval of two hours' relief after having been coughed out.

CASE 7.—Grace T——, aged four years and six months, was admitted to hospital on April 12th. Previous history: Had suffered from enlarged tonsils since previous summer; sore-throat one week. Had breathed badly for twenty-four hours. When admitted, at 11.15 A.M., the child was fat, with blue lips, crowing inspiration, and retraction of ribs. Fauces and pharynx were covered with membrane. After intubation the child coughed for a few minutes, then complete relief followed. Temperature 99°. At 10.20 P.M. there was frequent coughing, with much mucus. The tube was removed. Some membrane and much mucus were coughed up. The dyspnœa returned, and the tube was replaced after one hour.—13th: Passed a good night. Took food freely. Temperature 103°.—14th: Breathing quite easy; tube removed, but after one hour dyspnœa returned, and the tube was replaced.—16th: Tube coughed up during the evening, and dyspnœa returned very rapidly; after fifteen minutes tube replaced.—19th: An attempt was made to get her to do without the tube, but it had to be reinserted half an hour afterwards.—21st: Tube taken out, and was not again required.—May 3rd: Discharged well.—*Remarks:* Intubation was performed five times. The tube was coughed out once, and removed three times (once for the purpose of cleaning), before it was no longer required. The tube was worn nine days altogether.

(To be concluded.)

ON THE

SYMPTOM OF PAIN IN SLOW INTRA-PERICARDIAL HÆMORRHAGE.

BY W. J. NAISMITH, M.D. EDIN., F.R.C.S.E (EXAM.),
MEDICO-LEGAL EXAMINER IN CROWN CASES FOR SOUTH AYRSHIRE, SURGEON TO THE AYR COUNTY HOSPITAL.

II.

IN a previous number of THE LANCET—in that, namely, of July 11th, 1885—I had occasion to direct attention to certain cases of slow intra-pericardial hæmorrhage, in which severe abdominal pain appeared, *inter alia*, to be the most salient and distressing symptom. Three instances were there adduced, occurring in the course of medico-legal practice, which had been caused respectively, (1) by rupture of an aortic aneurysm; (2) by rupture of the right auricle; and (3) by a stab of the left ventricle; a brief description of each case, with the detailed result of its post-mortem verification, being duly appended. It is to be noted that while, on the one hand, no attempt was made to ignore or minimise the just signification of certain other of the more usual and recognised symptoms of this mishap, so on the other hand the suggestion was carefully avoided that intense abdominal pain in these cases was to be regarded as at all an invariable or even common accompaniment. And this with good reason, or we should have heard more about it. Indeed, in the very last case of which I have cognisance, ably reported in a contemporary by Mr. Samuel Clarke Noble of Kendal, the patient, who lived five days and a half with a ruptured left ventricle, "only complained of pain at the præcordia," and had, therefore, deductively, no abdominal pain at all. My sole endeavour was to set forth that it was at least an occasional feature of this form of thoracic hæmorrhage, occurring with such concentrated intensity as to mask the real issue, and, in short, prove diagnostically misleading; "that," I quote the passage, "there may also occur in a certain proportion of cases of slow intra-pericardial hæmorrhage this symptom of abdominal pain, so marked as to lead either to a diagnosis of peritoneal or enteric (inflammatory) mischief, or to the refusal of a death certificate" (on suspicion of poison). Now I have another case (the fourth), attended by Dr. Lawrie of Ayr, and reported with his approval, which further illustrates this proposition. I had no knowledge whatever of its history or details till, after death, it became the subject of medico-legal investigation on the part of the Crown.

At 6.30 A.M. of May 7th, 1888, Mrs. F. B——, a field worker, about forty-eight years of age, walked a distance of three miles and a half to her work in the fields. The police information states that for some years she had had occasional attacks of pain in the chest and breathlessness, but in the intervals was apparently well and fit for her usual employment. At 8 A.M.—that is, an hour and a half after leaving home—she became suddenly very ill, vomiting repeatedly, and complaining of much pain in her "belly." She was taken home in a cart, but medical aid was not obtained till next day. Dr. Lawrie, who then saw her, depones: "I saw deceased at 10.30 A.M., and found her in bed complaining of very severe pain in the epigastric region, but not in the heart. She told me she had been taken ill in the fields the morning before, and had suffered the same pain as she had now; that she had vomited before being brought home, and had done so considerably since (no vomited matters had

Digitized by Google

been preserved); and that she had suffered this epigastric pain all night long, indeed since ever she took ill. She was in so much agony as to be unable to explain anything. I thought her suffering from inflammation of the stomach or peritoneum, and said so, ordering stimulants, as there was great debility, and poultices to the abdomen. There was nothing noticeable in the character of the breathing. I had barely left the house, not having gone far, when I was recalled, and was only in time to see deceased expire, after an illness, I understand, of about twenty-six hours. It subsequently occurred to me that the death might have been due to irritant poisoning, though, from the absence of marks on the mouth, not by the more usual corrosives. I understood the vomit had all gone on the floor." In short, a certificate of death from natural causes being, in the circumstances, properly refused, I was instructed by order of the Procurator Fiscal, to make, in conjunction with the medical attendant, whose precognition I have just quoted, a post-mortem examination.

The following are detached excerpts from the report, selected solely in respect of their relevancy, and irrespective of their order of sequence in the body of that document.

"The body, which was that of a female about fifty years of age, was well nourished, bordering on obesity. ..... There were no marks of vomiting or staining of the lips, tongue, or hands. ..... The stomach and gullet, which were ligatured and removed for separate examination along with the upper portions of the small intestine, were all empty, healthy, and normal, exhibiting no erosion or inflammatory action on their lining surfaces. Some adhering mucus in the stomach had the usual acid, but no other distinctive, odour.... The other abdominal organs and the peritoneum were healthy and normal. ..... On opening the chest the pericardial sac was observed to be livid and tensely distended with large clots and dark fluid blood, which entirely surrounded and compressed the heart. This effusion was discovered to have found exit through a minute opening in an aneurysm of the size of a bantam's egg, involving the base or commencement of the aorta, that portion of it—namely, which is situate within the pericardial precinct. The aneurysm occupied the front and left lateral portion of the vessel, but may be considered to be of the spurious, diffuse, or consecutive type; for by a process of ulcerative thinning an opening of the size of a threepenny-piece communicated with a sacculated condition of the corresponding portion of the pericardium itself. The outer or cardiac wall of the tumour, therefore, consisted of the pericardium only; and it was found that, on its anterior aspect, a minute opening not larger than a single grain of rape seed, was the point where the hæmorrhage had gained access to the pericardial cavity. The aorta exhibited the usual appearances of atheromatous disease. ..... The heart was of normal size, but pale, soft, and friable; its right and left cavities almost empty and partially contracted, its valves fairly competent; pericardial serosity, of course, ungaugeable. ..... Opinion: From the foregoing examination of the body of the said F. B., we are of opinion that death was caused by the rupture of an aortic aneurysm; and, from the small size of the rupture, that death did not occur suddenly, but after the lapse of some hours."

This is the case, and it only remains to add that for its elucidation it is a fortunate circumstance that a post-mortem was ordered. It certainly would not have been but for the suggestion of poison which I have recorded. My Scottish *confrères* will bear me witness when I affirm that in this country the medico-legal post-mortem examination has, from a scientific or pathological point of view, ceased, within the last few years only, to exist; and that in respect of its criminal relation it is, in effect, no longer investigatory and detective in its function, but has degenerated to a merely confirmatory procedure. That is to say, that the fact of a death being sudden and unaccountable is now no longer held, as formerly, to demand or justify a post-mortem examination; that as the authorities are not concerned to know the exact scientific cause of death, the mere looking at the outside of the body, and thereafter granting a certificate of "death from natural causes," is all that the nearest medical practitioner is expected to do when directed to proceed to examination, and he is, without the smallest experience, quite as competent as the most highly trained medical jurist for the task; so, indeed, is the nearest village constable. It is, in point of fact, now laid down—which of course disposes of the discretionary power which procurators fiscal are assumed by their instructions to possess—that no post-mortem examination shall be ordered in a given case, unless some "circumstance of suspicion" appears in the police report. On the criminal aspect of this subject I may have something to say on another occasion, and have only referred to it here in order to accentuate the value of medico-legal investigation on pathological grounds.

Ayr, N.B.

ON THE

EFFECT UPON THE HUMAN BODY OF A DIET CONSISTING ENTIRELY OF LEAN MEAT AND WATER.

BY GEORGE HERSCHELL, M.D. LOND.

CAN life and health be sustained indefinitely upon a diet of lean meat and water without any farinaceous food at all? Physiologists tell us that it cannot; experience seems to negative their assertion. It is highly desirable that this question should be cleared up and finally set at rest, both from a practical and from a purely scientific point of view. A diet of lean meat is now being advocated for several purposes in practical medicine, and it is of the highest importance that we should know for certain for what period it can be carried on without injury to the patient. In this country it is being used chiefly for the reduction of obesity, but in New York Dr. Salisbury and several other physicians are making an extensive use of a diet consisting entirely of lean meat and water, not only for that purpose, but also in the treatment of dyspepsia, phthisis, ectasia of the stomach, and in the absorption of new growths. In the latter case Dr. Salisbury claims that by increasing the metabolism of the body recently formed tumours can be absorbed. In order to procure these results, he and his followers continue the use of a diet consisting entirely of lean meat and water for a period of at least several months, and, they state, not only with perfect impunity, but with absolute benefit to the general health of the patient.

Let us now turn to Landois and Stirling, which we may accept as one of the most recent of the standard text-books on physiology, and see what they say upon the subject. On page 482: "To obtain the 448 grms. of carbohydrates necessary to support him, a man must eat 2261 grms. of beef." Again, on page 485: "A man is not able to maintain his metabolism in equilibrium on a purely flesh diet; if he were compelled to live on such a diet, he would succumb. ..... If a man is to obtain 280 grms. C. from a flesh diet, he must consume, digest, and assimilate more than two kilos in twenty-four hours. *But our digestive organs are unequal to this task for any length of time.*" The reason why I am bringing this subject before the notice of the profession is that there are now being exhibited at the Westminster Aquarium a family of savages who have lived all their lives on nothing except lean meat, fish, and water, without succumbing, as we are told they ought to have done. Those interested in the physiology of diet have now an opportunity which they have never had before in this country of investigating a purely carnivorous man.

They are a family of cannibals from Terra del Fuego, belong to the tribe of Onas, and consist of five adults and two children. The adult male is thirty years of age, of normal weight and development, takes little or no exercise, and eats every twenty-four hours 5½ lb. of lean cold boiled horseflesh, 2 lb. of raw fish, and one or two eggs, and drinks about four pints of water at the most, probably rather less. As near as can be ascertained, he passes about the normal quantity of urine in the twenty-four hours, and a sample passed about three hours after his last meal at night yielded the following results on examination. Sp. gr. 1020; faintly acid, no albumen, no sugar, an excess of phosphates, but urea fifteen grains to the ounce, and uric acid one-sixth of a grain per ounce only!

A careful study of the case presents to us the following facts for our consideration. 1. It is generally admitted that the inhabitants of cold climates must eat more fat and farinaceous food than those of warmer parts. Now in the island where these people come from there is nearly always snow on the ground, and notwithstanding that they reject
